Inversion symmetric non-Hermitian Chern insulator

H. C. Wu, L. Jin and Z. Song
School of Physics, Nankai University, Tianjin 300071, China

We propose a two-dimensional non-Hermitian Chern insulator with inversion symmetry, which is anisotropic and has staggered gain and loss in both $x$ and $y$ directions. In this system, conventional bulk-boundary correspondence holds. The Chern number is a topological invariant that accurately predicts the topological phase transition and the existence of helical edge states in the topologically nontrivial gapped phase. In the gapless phase, the band touching points are isolated and protected by the symmetry. The degenerate points alter the system topology, and the exceptional points can destroy the existence of helical edge states. Topologically protected helical edge states exist in the gapless phase for the system under open boundary condition in one direction, which are predicted by the winding number associated with the vector field of average values of Pauli matrices. The winding number also identifies the detaching points between the edge states and the bulk states in the energy bands. The non-Hermiticity also supports a topological phase with zero Chern number, where a pair of in-gap helical edge states exists. Our findings provide insights into the symmetry protected non-Hermitian topological insulators.

I. INTRODUCTION

The topological phase of matter in condensed matter physics has been attracting considerable research interest and has been widely explored [1–7]. Open systems ubiquitously exist in physics [8–10], particularly, the optical and photonic systems; these are mostly non-Hermitian because they interact with the environment [11–16]. Currently, topological systems extend into the non-Hermitian region [17–21], and the nontrivial topological properties are studied in one-dimensional (1D), two-dimensional (2D), and three-dimensional (3D) systems, including the Su-Schrieffer-Heeger (SSH) model [22–24], Aubry-André-Harper (AAH) model [25–27], Rice-Mele (RM) model [28–30], Chern insulator [31–34], and Weyl semimetal [35–37].

Edge states in the parity-time ($\mathcal{PT}$)-symmetric systems are considered absent because the edge state with its probability localized at one system boundary is not $\mathcal{PT}$ invariant [21]. However, $\mathcal{PT}$-symmetric interface states can localize at the interface or domain wall of two configurations with different topologies [35–36]; a zero mode can appear at the interface of lattices in the same topological phase but with different non-Hermitian phases [37]. Both the types of interface states are topologically protected and robust to disorders. Topological edge states lasing in 1D [38–41] and 2D [42–45] have been reported recently; robust single-mode lasing prevails due to the topological protection. Non-Hermitian topological systems with $\mathcal{PT}$ symmetry are of primary focus [46–52]. Other symmetries, such as chiral-time ($\mathcal{CT}$) and charge-parity ($\mathcal{CP}$) symmetries, have been investigated recently [21, 41, 45, 48, 49, 51]. The topological aspects of non-Hermitian systems, including edge modes [34, 35], topological invariant [33, 34, 36, 42], band theory [32–34, 45–47], topological pumping [36, 39, 40, 48], classification [39, 50], high-order non-Hermitian topological systems [106, 111], semimetals [112, 117], and symmetry-protected topological phases and localized states have been investigated [90, 118–121]. The exceptional points (EPs) of non-Hermitian systems are connected by Fermi arcs [122–123] or form EP rings and surfaces [61, 126–128].

Notably, the bulk-boundary correspondence fails in some non-Hermitian topological systems [57, 61, 89, 129–132]. The spectrum under the periodical boundary condition (PBC) significantly differs from that under the open boundary condition (OBC), and the eigenstates under OBC are all localized at the system boundary (the non-Hermitian skin effect) [133]. The topological invariant can be constructed either from the biorthogonal norm [137], the non-Bloch bulk [133], or the singular-value decomposition of the Hamiltonian [140]. The reason for the breakdown of bulk-boundary correspondence is that an asymmetric coupling induces an imaginary Aharonov-Bohm effect [134, 135], the validity of the bulk-boundary correspondence can be maintained by chiral-inversion symmetry [136]. The boundary modes in non-Hermitian systems have been discussed on the basis of the transfer matrix method [133] and the Green’s function method [89, 134, 135]. The interplay between non-Hermiticity and non-Abelian gauge potential has been discussed [140]. In contrast to the topological phase transition, the invalidity of bulk-boundary correspondence, and the non-Hermitian skin effect, non-Hermiticity may not alter the topological phase transition and system topology [147]. A graphical approach has been proposed to visualize the topological phases in non-Hermitian systems [148].

Different from the non-Hermitian Chern insulators in Refs. [58–62], an inversion symmetric 2D non-Hermitian Chern insulator is proposed and the validity of conventional bulk-boundary correspondence is predicted in the end of Ref. [134]. However, more physical aspects including the topological invariant and the edge state are not discussed. In this study, the inversion symmetric non-Hermitian Chern insulator is investigated in detail; in
particular, the topological properties of the gapless phase as well as the technical aspect of topological characterization are systematically analyzed. Notably, the gain and loss are alternately added in the $x$ and $y$ directions in the inversion symmetric non-Hermitian Chern insulator. The non-Hermitian Aharonov-Bohm effect and skin effect are prevented by the inversion symmetry, and the conventional bulk-boundary correspondence is valid. The Chern number constructed from the system bulk is a topological invariant used to predict the topological properties of the Chern insulator. Different from the anomalous edge states that are localized in a single unit cell \[129\], and those that cannot be predicted by the bulk topology \[60\], a pair of helical edge states appear in the topologically nontrivial phase of the inversion symmetric Chern insulator under OBC. The gapless phase has band touching points in the Brillouin zone (BZ). The locations of the band touching degenerate points (DPs) are fixed and they do not change into pairs of EPs \[124\]. The band touching EPs are isolated and topologically protected, moving in the BZ and merging when they meet in pairs. Band touching varies the system topology and the existence of helical edge states. Moreover, non-Hermiticity creates a pair of topologically protected in-gap helical edge states in a novel phase with zero Chern number.

The remainder of the paper is organized as follows. In Sec. \[II\] we introduce the inversion symmetric 2D non-Hermitian Chern insulator. In Sec. \[III\] we discuss the energy bands, the phase diagram, and the topological characterization of the bulk Hamiltonian. In Sec. \[IV\] we demonstrate the energy spectrum and the helical edge states in different topological phases of the edge Hamiltonian, and we verify the validity of conventional bulk-boundary correspondence. In Sec. \[V\] we present the connection between the 2D non-Hermitian Chern insulator and other quasi-1D non-Hermitian topological systems with asymmetric couplings. In addition, we discuss possible experimental realization. Finally, in Sec. \[VI\] we summarize the main findings.

II. INVERSION SYMMETRIC NON-HERMITIAN CHERN INSULATOR

We investigate a non-Hermitian 2D topological system with inversion symmetry. The schematic of the lattice of the non-Hermitian 2D topological system is presented in Fig. 1. The lattice in the Hermitian case is a Chern insulator, constituted by vertical Creutz ladders \[149\]. The Creutz ladders are horizontally coupled with strength $t$. The intra-ladder rung represents a coupling with strength $m$. Couplings of strength $m$ and $t$ are alternated along the $x$ direction. Along the $y$ direction, the $t/2$ coupling has an additional $\pm \pi/2$ Peierls phase factor in the front, which results in magnetic flux $\pi$ in each plaquette, indicated by the shaded square in Fig. 1. The off-diagonal coupling strength in the plaquette is $t/2$, which is equivalent to spin-orbital coupling \[150\]. The lattice Hamiltonian in the real space is $H = H_0 + H_1$, consisting of the nearest-neighbor coupling term

$$H_0 = \sum_{i,j} \left[ \left( a_{i,j}^\dagger b_{i,j} + c_{i,j}^\dagger d_{i,j} \right) + \left( a_{i+1,j}^\dagger b_{i,j} + c_{i,j+1}^\dagger d_{i,j} \right) + \frac{it}{2} \left( a_{i,j}^\dagger c_{i,j} - a_{i,j-1}^\dagger c_{i,j} - b_{i,j}^\dagger d_{i,j} + b_{i,j-1}^\dagger d_{i,j} \right) \right] + \text{H.c.}, \quad (1)$$

and the off-diagonal coupling term

$$H_1 = \frac{t}{2} \sum_{i,j} \left( a_{i,j}^\dagger b_{i,j} + a_{i,j-1}^\dagger b_{i,j} + b_{i,j}^\dagger c_{i,j} + b_{i,j-1}^\dagger c_{i,j} \right) + \text{H.c.}, \quad (2)$$

where the operators $a_{i,j}^\dagger, b_{i,j}^\dagger, c_{i,j}^\dagger, d_{i,j}^\dagger$ are creation operators for the four sublattices in the unit cell $(i,j)$. The unit cell is indicated in Fig. 1 by the blue square with dashed lines. The system exhibits inversion symmetry, and the real space Hamiltonian $H$ is invariant under a rotation of $\pi$ with respect to the lattice center. The inversion symmetry in 1D systems is the reflection symmetry. The topological classification of non-Hermitian systems with reflection symmetry and the rich topological phases are studied \[103\].

We consider generalization of the non-Hermitian system holding inversion symmetry. The gain and loss with rates $\gamma$ are alternately introduced in both $x$ and $y$ directions of $H$: the non-Hermitian Hamiltonian is $\mathcal{H} = H + H_\gamma$, and consists of staggered gain and loss

$$H_\gamma = i\gamma \sum_{i,j} \left( a_{i,j}^\dagger a_{i,j} - b_{i,j}^\dagger b_{i,j} - c_{i,j}^\dagger c_{i,j} + d_{i,j}^\dagger d_{i,j} \right). \quad (3)$$

Notably, the generalized non-Hermitian Chern insulator $\mathcal{H}$ holds the inversion symmetry and differs from other non-Hermitian Chern insulators without inversion symmetry in Ref. \[60, 61\]. The inversion symmetry ensures the presence of a zero imaginary magnetic flux \[133\]. Thus, the non-Hermitian skin effect is absent and the conventional bulk-boundary correspondence holds in the inversion symmetric non-Hermitian Chern insulator. The topological properties of the system can be retrieved from its bulk topology. In the following sections, the energy bands, phase diagram, topological characterization, and edge states are elucidated.

III. PHASE DIAGRAM AND TOPOLOGICAL CHARACTERIZATION

**Block Hamiltonian.** We apply the Fourier transformation $\rho_{k_x,k_y} = N^{-1/2} \sum_{l,s} e^{-ik_x l} e^{-ik_y s} \rho_{l,s}$ to the sublattices $\rho = a, b, c, d$: the Hamiltonian of the non-Hermitian system in the real space is rewritten in the momentum space, $\mathcal{H} = \sum_k \mathcal{H}(k)$. The Bloch Hamiltonian of the non-Hermitian system in the basis
\( \langle a_{k_x,k_y}^\dagger | \text{vac} \rangle, b_{k_x,k_y}^\dagger | \text{vac} \rangle, c_{k_x,k_y}^\dagger | \text{vac} \rangle, d_{k_x,k_y}^\dagger | \text{vac} \rangle \) reads

\[
\mathcal{H}(k) = \begin{pmatrix}
i\gamma & m + te^{-i k_x} & \Lambda_-(k_y) & \Lambda_+(k_y) \\
m + te^{i k_x} & -i\gamma & \Lambda_+(k_y) & -\Lambda_-(k_y) \\
\Lambda_-^*(k_y) & \Lambda_+^*(k_y) & m + te^{-i k_x} & i\gamma \\
\Lambda_+^*(k_y) & -\Lambda_-^*(k_y) & m + te^{i k_x} & i\gamma
\end{pmatrix}
\]

where we have \( \Lambda_+ (k_y) = t(1 + e^{i k_y})/2 \) and \( \Lambda_- (k_y) = i t(1 - e^{i k_y})/2 \). The Bloch Hamiltonian has the inversion symmetry \( \mathcal{P} \mathcal{H}(k) \mathcal{P}^{-1} = \mathcal{H}(-k) \) with \( \mathcal{P} = \sigma_x \otimes \sigma_z \), and the particle-hole (charge-conjugation) symmetry \( \mathcal{C} \mathcal{H}(k) \mathcal{C}^{-1} = -\mathcal{H}(-k) \) with \( \mathcal{C} = (\sigma_0 \otimes \sigma_z) \mathcal{K} \), where \( \mathcal{K} \) is the complex conjugation operation; \( \sigma_x, \sigma_y, \) and \( \sigma_z \) are the Pauli matrices; and \( \sigma_0 \) is a \( 2 \times 2 \) identity matrix.

The particle-hole symmetry ensures the spectrum of \( \mathcal{H}(k) \) to be symmetric about zero energy, with the energy bands given by

\[
E_{\pm \pm}(k) = \pm \sqrt{h_x^2 + h_y^2 + h_z^2}.
\]

where \( \mu = m + t \cos k_x + \gamma, \nu = m + t \cos k_x - \gamma, \) and \( h_{x,\pm} = \sqrt{\mu \nu} \pm t \cos (k_y/2), h_y = t \sin (k_y/2), h_z = t \sin k_x. \) For \( \mu \nu < 0, \sqrt{\mu \nu} \) is imaginary and the energy spectrum is complex. Highly defective exceptional lines (HDELs) appear at \( \mu \nu = 0 \), that is, when \( t \cos k_x = -\mu \pm \gamma \). The HDELs are fully constituted by EPs, and the energy levels are two-state coalesced in pairs at energy \( \pm \sqrt{t^2 + h_z^2} \). The energies are indicated by the black lines in Fig. 2.

Notably, the HDELs are EP lines across the BZ. The upper and lower bands shrink into two levels with opposite energies. In the BZ, zero to four HDELs symmetrically appear about \( k_x = 0 \) at different system parameters. In addition, the bandgap closes at zero energy, where the band touching points can be either DP \( h_{x,-\pm,=} = h_y = h_z = 0 \) or EPs. The inversion symmetry leads to an inversion symmetric distribution of the band touching points in the BZ and the band touching points always appear in pairs of \( (k_x,k_y) \) and \( (-k_x,-k_y) \). Figure 2 depicts the absolute value of the energy spectrum \( |E_{\pm \pm}(k)| \).

From Fig. 2(a) to Fig. 2(f), the non-Hermiticity increases from \( \gamma/t = 1/2 \) to \( \gamma/t = 5/2 \). The energy bands satisfy \( E_{+,\pm}(k_x,k_y) = E_{-,\pm}(k_x,-k_y + 2\pi) \). The two upper (lower) energy bands of the inversion symmetric non-Hermitian Chern insulator constitute an entire band without intersection if one of the two bands \( E_{+,\pm}(k) \) [\( E_{-,\pm}(k) \)] shifted by \( 2\pi \) along the \( k_y \) direction in the BZ. The constituted band is the upper (lower) band of the non-Hermitian Chern insulator constitute an entire band without intersection if one of the two bands \( E_{+,\pm}(k) \) [\( E_{-,\pm}(k) \)] shifted by \( 2\pi \) along the \( k_y \) direction in the BZ. The constituted band is the upper (lower) band of the non-Hermitian Chern insulator constitute an entire band without intersection if one of the two bands \( E_{+,\pm}(k) \) [\( E_{-,\pm}(k) \)] shifted by \( 2\pi \) along the \( k_y \) direction in the BZ.

Phase diagram. To analyze the phase diagram of the system in detail, we consider \( t \) as the unit. The phase diagram of the non-Hermitian Chern insulator is depicted...
in Fig. 3 as a function of system parameters $m$ and $\gamma$. In the Hermitian situation with $\gamma = 0$, the energy bands are gapped for $m/t \neq 0, \pm 2$ and the Chern number is $C = 1$ ($C = -1$) for $0 < m/t < 2$ ($-2 < m/t < 0$). In case $|m/t| > 2$, the Chern number is zero. In the non-Hermitian situation with $\gamma \neq 0$, instead of splitting into pairs of EPs [124], the band touching DPs appear at fixed positions in the BZ, with their appearance distinguishing the topologically nontrivial and trivial phases. In the gapless phase, the band touching DPs occur at $\sqrt{m^2 - t \cos(k_y/2)} = h_y = h_z = 0$, which depends on non-Hermiticity given by
\[ \gamma^2 = (m \pm t)^2 - t^2. \] (6)

This is indicated by the red curves in the phase diagram in Fig. 3. The DP locations are fixed in the BZ and at $(k_x, k_y) = (0, 0)$ for $\gamma^2 = (m + t)^2 - t^2$ and at $(k_x, k_y) = (\pi, 0)$ for $\gamma^2 = (m - t)^2 - t^2$.

The yellow and orange regions in Fig. 3 represent the gapless phase with two symmetry protected EPs. The EPs possess distinct topology from that of DPs due to the bifurcation linking the Riemann surface [151, 152]. The band touching points are EPs with fractional charge $\pm 1/2$ according to the definition of non-Hermitian winding number $W_{\text{EP}} = -\left(2\pi\right)^{-1} \int_{\Gamma} \nabla_k \arg \left(E_+ (k) - E_- (k)\right) \, dk$ [92], where $\Gamma$ is a closed loop in the momentum space. In these gapless regions, the symmetry protected EPs move in the BZ as system parameters, and merge when they meet in the BZ due to topological phase transition; then, the number of EPs in the BZ reduces to one and the topological features of EP change. As $\gamma$ increases, the separate upper and lower bands become closer and may touch at $|\gamma/t| > 1$. The band touching EPs appear in the regions
\[ (|m| - t)^2 + t^2 \leq \gamma^2 \leq (|m| + t)^2 + t^2. \] (7)

At $m = 0$, we have $\gamma^2 = 2t^2$; the EPs form EP lines along $k_y = \pi$. Otherwise at $m \neq 0$, two EPs appear at $(k_x, k_y) = (\pm \theta, \pi)$ when the system is within the gapless regions, where $\theta$ is obtained from $\cos \theta = (\gamma^2 - m^2 - 2t^2) / (2mt)$. The EPs in the BZ appear and move along $k_y = \pi$ as system parameters, and symmetrically distribute about $k_x = 0$ with different chiralities [151, 152]. At the boundary of the gapless phase represented by the black curves in the phase diagram Fig. 3, two EPs merge to one hybrid EP [151, 152, 155] and locate at $(k_x, k_y) = (0, \pi)$ for $\gamma^2 = (m + t)^2 + t^2$ and at $(k_x, k_y) = (\pi, \pi)$ for $\gamma^2 = (m - t)^2 + t^2$; the EP can be checked by substituting $(k_x, k_y)$ into $\mathcal{H}(k)$. The band structures in the gapless phase with different EP distributions are demonstrated in Figs. 3(b)–3(c).

The white region in the phase diagram (Fig. 3) indicates the topologically trivial phase with zero Chern number; topologically protected edge states are absent in this phase under OBC in either direction. Due to the large imaginary part of energy bands at large non-Hermiticity of $\gamma^2 > (|m| + t)^2 + t^2$, the energy bands are fully complex and separable. The green region also represent a phase with zero Chern number; however, in-gap topologically protected edge states exist under OBC in the $y$ direction; this point is elucidated in Sec. IV.

To characterize the topological properties of the inversion symmetric non-Hermitian Chern insulator, it is convenient to transform the Bloch Hamiltonian $\mathcal{H}(k)$ into a two-band model. After a similar transformation
\[ \mathcal{M} = \begin{pmatrix} \sqrt{\mu} & -i\sqrt{\nu} & 0 & 0 \\ -i\sqrt{\nu} & \sqrt{\mu} & 0 & 0 \\ 0 & 0 & \sqrt{\nu} & -i\sqrt{\nu} \\ 0 & 0 & i\sqrt{\nu} & \sqrt{\mu} \end{pmatrix}, \] (8)

is performed, the Bloch Hamiltonian of the non-Hermitian Chern insulator changes into
\[ \mathcal{M} \mathcal{H}(k) \mathcal{M}^{-1} = \begin{pmatrix} t \sin k_x & \sqrt{\mu\nu} & 0 & te^{ik_y} \\ \sqrt{\mu\nu} & -t \sin k_x & 0 & 0 \\ 0 & t & t \sin k_x & \sqrt{\mu\nu} \\ te^{-ik_y} & 0 & \sqrt{\mu\nu} & -t \sin k_x \end{pmatrix}, \] (9)

which possesses a two-site unit cell instead of a four-site one because of the repeated diagonal $2 \times 2$ matrix $\sqrt{\mu\nu} + (t \sin k_x) \sigma_z$. This is in accordance with the spectrum presented in Fig. 2 where two upper (lower)
bands can form a single band after one of them shifts by $2\pi$ in the $k_y$ direction.

The equivalent two-band Bloch Hamiltonian $h(k) = B \cdot \sigma$ obtained from $\mathcal{H}(k)$ after a similar transformation [Eq. (9)] reads

$$h(k) = B_x \sigma_x + B_y \sigma_y + B_z \sigma_z. \quad (10)$$

The Bloch Hamiltonian is a spin-1/2 in a complex effective magnetic field $B = (B_x, B_y, B_z)$ with $B_z = \sqrt{\mu B} + t \cos k_y$, $B_y = - t \sin k_y$, $B_z = t \sin k_z$; and $\sigma = (\sigma_x, \sigma_y, \sigma_z)$. In the Hermitian limit $\gamma = 0$, the effective magnetic field $B_x = m + t \cos k_x + t \cos k_y$, $B_y = - t \sin k_y$, $B_z = t \sin k_z$ is real, and $h(k)$ follows the Qi-Wu-Zhang model \[166\]. Notably, $k_y$ in the two-band $h(k)$ corresponds to $2k_y$ in the four-band $\mathcal{H}(k)$. The energy bands of $h(k)$ are depicted in the Appendix A as a comparison with the corresponding energy bands of $\mathcal{H}(k)$ depicted in Fig. 2.

We emphasize that $\mu \nu = 0$ is the HDELS of the four-band Bloch Hamiltonian $\mathcal{H}(k)$. In contrast, the equivalent two-band Bloch Hamiltonian $h(k)$ is Hermitian at $\mu \nu = 0$; thus, the HDELS are absent in $h(k)$. $\mathcal{H}(k)$ and $h(k)$ are related by the similar transformation $\mathcal{M}$ at $\mu \nu \neq 0$; they are not related by the similar transformation $\mathcal{M}^{-1}$ at $\mu \nu = 0$) does not exits) although their energy bands are identical. In this sense, the HDELS are removed and absent in $h(k)$. Notably, the wave function singularity in $\mathcal{H}(k)$ does not appear at the HDELS; thus, the equivalent two-band Bloch Hamiltonian $h(k)$ carries the topological properties of $\mathcal{H}(k)$.

**Chern number in the gapped phase.** The Bloch Hamiltonian $h(k)$ describes an RM ladder with glider reflection symmetry \[167,168\], consisting of two coupled RM chains, and the inter-ladder leg coupling is $\sqrt{\mu B}$. In the regions that the energy bands are separated \[92\], the Chern number for the energy band is a topological invariant that characterizes the topological properties and the appearance of edge states of the system under OBC.

The eigenvalue is $\varepsilon_{\pm}(k) = \pm B$, where $B = (B_x^2 + B_y^2)^{1/2}$; the corresponding eigenstate is $|\psi_{\pm}(k)\rangle = N_{\pm}^{-1} |B_z \pm B_x + i B_y| T $, where $N_{\pm} = (|B_z \pm B_x|^2 + |B_x + i B_y|^2)^{1/2}$ and the eigenstate $|\psi_{\pm}(k)\rangle$ satisfies $\langle \psi_{\pm}(k)|\psi_{\pm}(k)\rangle = 1$. The wave function singularity occurs at $B_z \pm B_x + i B_y = 0$ \[4\] (Notably, the wave function singularity is not refer to as the EP, where eigenstate coalescence). The Berry connection for the eigenstate is $A_{\pm}(k) = -i \langle \phi_{\pm}(k)|\nabla_k |\psi_{\pm}(k)\rangle \tag{60} \tag{61} \tag{63}$ and the Berry curvature is $\Omega_{\pm}(k) = \nabla_k \times A_{\pm}(k)$, where $|\phi_{\pm}(k)\rangle$ is the eigenstate of $h(k)$ with corresponding energy bands $\varepsilon_{\pm}(k)$. The eigenstates of $h(k)$ and $h^\dagger(k)$ constitute a biorthogonal basis. $|\psi_{\pm}(k)\rangle$ and $|\phi_{\pm}(k)\rangle$ are known as the right and left eigenstates, and they satisfy biorthogonal condition $\langle \phi_{\pm}(k)|\psi_{\pm}(k)\rangle = \delta_{kk'} \tag{169} \tag{170}$. The biorthogonal condition does not settle the normalization coefficients of the left and right eigenstates; associated with the normalization of right eigenstate $\langle \psi_{\pm}(k)|\psi_{\pm}(k)\rangle = 1$, the normalization coefficients of eigenstates are fixed. The Chern number is defined as the integration of $\Omega_{\pm}(k)$ over the whole first BZ

$$C_{\pm} = \frac{1}{2\pi} \int_{BZ} dk_x dk_y \Omega_{\pm}. \quad (11)$$

The Chern number can be alternatively defined from other choice of Berry curvature based on the right and left eigenstates $\Omega_{\pm}(k) = -i \nabla_k \times |\psi_{\pm}(k)\rangle \langle \psi_{\pm}(k)|$, solely based on the right eigenstate $\Omega_{\pm}(k) = -i \nabla_k \times |\psi_{\pm}(k)\rangle \langle \psi_{\pm}(k)|$, and solely based on the left eigenstate $\Omega_{\pm}(k) = -i \nabla_k \times |\phi_{\pm}(k)\rangle \langle \phi_{\pm}(k)|$. Notably, the four definitions of Chern numbers are equivalent \[92\] \[147\].

The Chern numbers for the upper and lower bands are opposite $C_{\pm} = 1$. The Chern number for either band is capable of characterizing the topological properties of the corresponding phases. The Chern number different between two bands directly reflects the number of edge modes at the interface of two distinct bulks. At large non-Hermiticity, $\mu \nu < 0$, the Berry curvature $\Omega_{\pm}(k)$ is well-defined in the BZ. The wave function singularity results in a nonzero Chern number, which predicts the nontrivial topology and the existence of edge states. For the wave function with singularity, two gauges are used to describe the wave function. $|\psi_{\pm}(k)\rangle$ replaces $|\psi_{\pm}(k)\rangle$ in an area $D$ that encloses the singularity of $|\psi_{\pm}(k)\rangle$, that is, $|\psi_{\pm}(k)\rangle = |\psi_{\pm}(k)\rangle e^{i\phi_{\pm}(k)}$, $|\phi_{\pm}(k)\rangle = |\phi_{\pm}(k)\rangle e^{i\phi_{\pm}(k)}$. The phase dependence between two gauges results in a relation between two Berry connections $A_{\pm}(k) = A_{\pm}(k) + \nabla_k \phi_{\pm}(k)$. The Stokes' theorem indicates that the Chern number equals the winding of the variation of $\phi_{\pm}(k)$ along the loop that encloses the area $D$.

The Berry curvature $\Omega_{\pm}(k)$ is ill-defined at $\mu \nu = 0$, where eigenstates of $\mathcal{H}(k)$ coalesce in pairs and one-half of eigenstates vanish. Notably, $\sqrt{\mu B}$ changes between real and imaginary as $k_y$ crosses $\mu \nu = 0$ in the BZ. Consequently, $B_y(b_{x,y})$ is not smooth and the Berry curvature $\Omega_{\pm}(k)$ is ill-defined at $\mu \nu = 0$. However, the Chern number is an integral of the Berry curvature in the entire BZ, the ill-defined Berry curvatures are only a finite number of lines; and the wave function singularity does not appear at $\mu \nu = 0$. Thus, the Chern number determined by the wave function singularity in the BZ is not affected by the presence of ill-defined Berry curvatures at $\mu \nu = 0$. The nonzero (zero) Chern number $C = \pm 1$ (0) is verified from the numerical simulation in the discretized BZ \[171\]. The numerical results of the Berry curvature are exemplified in Fig. 4 for the topologically nontrivial phase with $C = 1$ and the topologically trivial phase with $C = 0$. In Fig. 4(a), $\mu \nu = 0$ is the boundary between Hermitian and non-Hermitian $h(k)$; $h(k)$ is Hermitian when $\mu \nu > 0$, but is non-Hermitian when $\mu \nu < 0$.

**Winding number in the gapless phase.** In the gapless phase, the Chern number is not available, we define a vector field $F_\pm = (|\sigma_{x,y}|, |\sigma_{y,z}|, |\sigma_{z,x}|)$ to characterize the topological features of the gapless phase. The vec-
tor field $\mathbf{F}_\pm$ is defined by the average values of Pauli matrices: $F_{\pm} = \langle \sigma_x, \gamma \rangle = \langle \psi_+ | | \sigma_x, \gamma \rangle | \psi_+ \rangle$ and the subscript $\pm$ indicate the index of the energy band. Under the normalization of the right eigenstate $| \psi_\pm(k) \rangle$, the amplitude of the vector field is unity, that is, $|F_\pm|^2 = 1$. The vector field is depicted in Fig. 5 to elucidate that a winding number associated with $\mathbf{F}_\pm$ accurately predicts the (non)existence of edge states in the gapless phase. For the system under OBC in the $y$ direction [Fig. 6(b)], the trivial and nontrivial windings of the planar vector field $F_{\pm,xy} = \langle \sigma_x \rangle \pm \langle \sigma_y \rangle$ as $k_y$ varying a period predict the attaching point of the edge states and the bulk states in the complex energy bands

$$w_\pm = (2\pi)^{-1} \int_{0}^{2\pi} dk_y \nabla_{k_y} \phi_\pm,$$

where $\tan \phi_\pm = F_{\pm,xy}/F_{\pm,xx}$. The winding numbers of two energy bands are identical, that is, $w_+ = w_-$. The nontrivial $2\pi$ varying direction accumulation of the planar vector field $F_{\pm,xy} = \langle \sigma_x \rangle \pm \langle \sigma_y \rangle$ in a period of $k_x$ predicts the edge states for the system under OBC in the $x$ direction [Fig. 6(a)]; correspondingly, $w_+ = (2\pi)^{-1} \int_{0}^{2\pi} dk_x \nabla_{k_x} \phi_\pm$ with $\tan \phi_\pm = F_{\pm,xy}/F_{\pm,xx}$ and $w_\pm$ predicts the topological phase transition at $k_y = \pi/2$. Notably, the topological phase transition at $k_y = \pi/2$ in $h(k)$ indicates the existence of edge states in the region $k_y = [-\pi, \pi]$ as depicted in Fig. 6 for $\mathcal{H}$ under OBC in the $x$ direction. This is because the folded BZ in the $k_y$ direction of $h(k)$ yields the BZ of $\mathcal{H}(k)$.

FIG. 4. Berry curvature in the BZ. Chern number as a summation of the Berry curvature in the entire BZ yields $C = 1.00$ for (a) $\gamma = 1/2$ and $C = 0.00$ for (b) $\gamma = 5/2$ at $m = t = 1$. The BZ is equally cut into $30 \times 30 (150 \times 150)$ pieces in the numerical calculation for the upper (lower) panel. At $k_z = 2\pi/3, 4\pi/3$ in (a), $\mu \nu = 0$ and $h(k)$ is Hermitian; $\mu \nu = 0$ is absent in (b).

FIG. 5. The planar vector field $F_\pm$ for the lower band of $h(k)$. (a) $\gamma = 3/2, k_y = 0$; (b) $\gamma = 2, k_x = 0$; (c) $\gamma = 3/2, k_y = \pi$; (d) $\gamma = 2, k_x = \pi$. $F_\pm$ at $k_y = \pi$ in $h(k)$ predicts the topological properties of $\mathcal{H}(k)$ at $k_y = 0$. Other system parameters are $m = t = 1$. (a) and (d) correspond to $w_- = 0$; (b) and (c) correspond to $w_+ = 1$.

IV. ENERGY BANDS AND EDGE STATES OF THE EDGE HAMILTONIAN

The bulk topology of the system determines the phase diagram, which accurately predicts the topological phase transition and the (non)existence of edge states in different topological phases. In this section, we elucidate the role played by the Chern number for the gapped phase and the winding number for the gapless phase in the topological characterization through the investigation of the energy bands and edge states under different OBC only in the $x$ and $y$ direction, respectively. The PBC and OBC spectra are not dramatically different from each other owing to the validity of conventional bulk-boundary correspondence protected by the inversion symmetry.

1D edge Hamiltonian under OBC. The system under OBC is referred to the edge Hamiltonian because it is generated by truncating the bulk Hamiltonian in a certain way. The two-dimensional Chern insulator reduces

FIG. 6. (a) [(b)] Schematic of the 1D projection at set $k_y (k_x)$ of the 2D inversion symmetric non-Hermitian Chern insulator. (a) Quasi-1D SSH ladder. (b) Quasi-1D Creutz ladder. The green (red) solid circle indicates the site with gain (loss).
to a non-Hermitian quasi-1D SSH ladder or quasi-1D Creutz ladder at a fixed momentum in the $y$ or $x$ direction (Fig. 6), respectively. The non-Hermitian quasi-1D Creutz ladder is equivalent to a 1D RM chain with asymmetric couplings presented alternately (see Sec. V for more detail).

For the Chern insulator under PBC in the $y$ direction and OBC in the $x$ direction, we apply the Fourier transformation in the $y$ direction. This projection gives a quasi-1D SSH ladder with momentum $k_y$-dependent couplings and staggered on-site potentials, as presented in Fig. 6(a). Similarly, for the Chern insulator under PBC in the $x$ direction and OBC in the $y$ direction, the projection lattice reduces to a quasi-1D Creutz ladder with a momentum $k_x$-dependent couplings in the inter ladder, as presented in Fig. 6(b).

We study the inversion symmetric non-Hermitian Chern insulator under PBC and OBC in the $y$ and $x$ directions, respectively. The upper panel of Fig. 7 depicts the spectra under PBC in the $x$ direction and under OBC in the $y$ direction; the lower panel of Fig. 7 depicts the spectra under PBC in the $y$ direction and under OBC in the $x$ direction at the same system parameters as those in the upper panel of Fig. 7.

Gapped phase. In the gapped phase, the Chern number is the topological invariant. The nonzero Chern numbers of the upper and lower bands in the topologically nontrivial phase indicate the existence of a pair of topologically protected helical edge states under OBC. The two helical edge states in a pair localize at the left and right edges of the 1D system, respectively. The white region with zero Chern number are topologically trivial phases without topologically protected edge states. The green region with zero Chern number consists of in-gap edge states. We first discuss the topological edge states and then discuss the topological phase transition in different gapped phases.

Figure 7(a) depicts the spectrum in the topologically nontrivial phase with $C = 1$; a pair of topologically protected helical edge states exist, localizing on the left and right boundaries of the 1D lattice, respectively. In Fig. 7(d), the system is in the topologically trivial region, the white region with $C = 0$, the edge state is absent. The OBC spectra in the green region with $C = 0$ are depicted in Fig. 7(e). In-gap edge states are observed under OBC in the $y$ direction; both edge states are detached from the upper and lower bands; this is indicated by the zero Chern number and presented in the inset of Fig. 7(e). Two in-gap edge states cross at $k_x = 0, \pi$. As non-Hermiticity increases, the in-gap edge states may touch the upper and lower bands at $\gamma \geq 1$ with the diminishing gap at $k_x = \pm \pi/2$. By contrast, the topologically protected helical edge states are absent for the system under OBC in the $x$ direction in the lower panel. We generalize the polarization into the non-Hermitian region to characterize the topological in-gap edge states $[172, 173]$. The polarization is defined by the Berry connection based on the left and right eigenstates; the projection in the $x$ ($y$) direction is $P_{\pm,x(y)} = (2\pi)^{-2}\int_{BZ} dk_x dk_y A_{\pm,x(y)}(k)$, where $A_{\pm,x(y)}(k) = -i \langle \phi_{\pm}(k) | \nabla_{k_{x(y)}} | \psi_{\pm}(k) \rangle$. In the green region with $C = 0$, the wave function has no singularities; thus, the polarization is well defined and we

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig7.png}
\caption{Energy spectrum for $\mathcal{H}$ under OBC. The upper (lower) panel represents the energy spectra of the system under PBC in the $x$ ($y$) direction, but under OBC in the $y$ ($x$) direction; the schematic is in Fig. 6. The parameters are (a) $\gamma = 1/2$, (b) $\gamma = 3/2$, (c) $\gamma = 2$, (d) $\gamma = 5/2$; other parameters are $m = t = 1$ in (a)-(d). In (e), $m = 0$, $t = 1$, and $\gamma = 1/2$. The band energy repetition period is $\pi$ for the upper panel of (e), where the inset on the right side are zoom-in plot of the area in the dashed box. The edge states reside inside the bandgap without touching the bulk bands. The parameters in the plots are indicated by the solid dots in the phase diagram shown in Fig. 3. The black (red) line is the real (imaginary) part of band energy. The number of unit cells of 1D projection lattices is twenty.}
\end{figure}
have the 2D Zak phases associated fractional polarization \( P_{-y} = -1/2 \) and \( P_{-x} = 0 \) \(^{172}\). The in-gap edge states are topologically protected, being robust to the inversion symmetric perturbations that without breaking the pseudo-Hermiticity. Two in-gap edge states remain in the bandgap and are detached from the bulk bands. The details about the robustness of in-gap edge states are provided in the Appendix B.

The appearance of band touching affects the (non)existence of topologically protected helical edge states. We elaborate this point by considering gapped phases in the regions of \( m > 0 \) and \( \gamma < 1 \). Notably, the inversion symmetric 2D non-Hermitian Chern insulator is anisotropic. In the green region of the phase diagram, the helical edge states appear only in the system under OBC in the \( y \) direction [upper panel of Fig. 2(e)]. Between the green and cyan regions, the system experiences a band touching with DP at \( (k_x, k_y) = (0, 0) \) [Fig. 2(d)]. Thus, for the system under OBC in the \( y \) direction, the in-gap helical edge states crossing at \( k_\gamma = 0, \pi \) change into helical edge states that connect the upper and lower bands and cross only at \( k_x = \pi \) [upper panel of Fig. 2(a)]. As \( m \) continuously increases, the system experiences a band touching with DP at \( (k_x, k_y) = (\pi, 0) \) and the helical edge states in the cyan region crossing at \( k_x = \pi \) are destroyed and disappear in the white region. Similarly, for the system under OBC in the \( x \) direction, the helical edge states crossing at \( k_y = 0 \) are formed after the system comes across the band touching with DP at \( (k_x, k_y) = (0, 0) \) and enters the cyan region in the phase diagram. As \( m \) continuously increases, the system experiences a band touching with DP at \( (k_x, k_y) = (\pi, 0) \) and \( (0, 0) \) at increasing \( k_y = 0 \) are destroyed and disappear in the white region.

**Gapless phase.** In the gapless phase, the helical edge states appear only under OBC in one direction and are predicted by the winding number \( w_\pm \) associated with the vector field \( \mathbf{F}_\pm \). The nonzero winding of the vector field predicts the presence of edge states detaching the bulk band. The planar vector field \( \mathbf{F}_{-xy} \) is depicted in Figs. 5(a) and 5(b). The winding number is \( w_- = 0 \) for Fig. 5(a) and is \( w_- = 1 \) for Fig. 5(b), which predict the absence and presence of edge states at \( k_x = 0 \) for the system under OBC in the \( y \) direction in the upper panel of Figs. 5(b) and 5(c), respectively. The planar vector field \( \mathbf{F}_{-xx} \) in Figs. 5(c) and 5(d) are depicted. The winding number is \( w_- = 1 \) for Fig. 5(c) and is \( w_- = 0 \) for Fig. 5(d), which predict the presence and absence of edge states at \( k_y = 0 \) for the system under OBC in the \( x \) direction in the lower panel of Figs. 5(b) and 5(c), respectively.

Topologically protected helical edge states exist in the orange region of the phase diagram in the gapless phase only for the OBC in the \( y \) direction. We consider a process with increasing non-Hermiticity. The system first experiences a nontrivial phase with \( C = 1 \) in the cyan region, then it enters the gapless phase, and finally it stays in the trivial phase with \( C = 0 \) in the white region. For the system under OBC in the \( y \) direction, the helical edge states cross at \( k_x = \pi \). As non-Hermiticity increases, the system enters the gapless phase in the yellow region from the cyan region. The EPs appear at \( (k_x, k_y) = (\pi, \pi) \) and then the \( k_x \) position of EPs changes as \( \gamma \) increases. Thus the helical edge states crossing at \( k_x = \pi \) are destroyed by non-Hermiticity [upper panel of Fig. 2(b)]; the crossing at \( k_x = \pi \) disappear. However, the DP appears at \( (k_x, k_y) = (0, 0) \) at increasing \( \gamma \); then the helical edge states cross at \( k_x = 0 \) and reappear until the EPs move to \( (k_x, k_y) = (0, \pi) \), which destroys the helical edge states once again. Thereafter, the system enters the trivial phase with \( C = 0 \) in the white region. For instance, as non-Hermiticity increases to \( \gamma = \sqrt{3} \) for \( m = t = 1 \), an additional band touching DP is formed at \( k_x = 0 \). Therefore, two helical edge states reappear in the orange region of the phase diagram at large non-Hermiticity as shown in the upper panel of Fig. 2(c); they cross at \( k_x = 0 \) instead of at \( k_x = \pi \) as in the \( C = 1 \) [upper panel of Fig. 2(a)]. At even larger \( \gamma = 5/2 \) in Fig. 2(d), the system is in the topologically trivial region without the presence of edge states.

By contrast, the topologically protected helical edge states exist in the yellow region of the phase diagram in the gapless phase only for the OBC in the \( x \) direction as elucidated in the lower panel of Fig. 4. For the system under OBC in the \( x \) direction, the helical edge states cross at \( k_y = 0 \) [lower panel of Fig. 2(a)]. The band touching EPs are fixed at \( k_y = \pi \) independent of non-Hermiticity, and do not affect the helical edge states until the DP appears at \( (k_x, k_y) = (0, 0) \) [Fig. 2(d)]. Then, the helical edges crossing at \( k_y = 0 \) are destroyed and disappear in the gapless phase in the orange region [lower panel of Fig. 2(c)]. The gapless phase with band touching DP is the boundary for the appearance of gapless topologically protected edge states.

**Edge states.** For the system under OBC in the \( y \) direction, the left edge state localizes at the left boundary and has eigen energy \( E_L(k_x) = -t \sin k_x \). We consider \( \psi_1 = 1 \) for convenience without loss of generality. The wave functions of the left edge state \( |\psi_L\rangle \) satisfies the recursion relation

\[
\begin{align*}
\psi_{2j} &= -i\psi_{2j-1}, \\
\psi_{2j+1} &= \left(1 - (2\gamma)/t - (m + t \cos k_x)/t\right)\psi_{2j-1}, \tag{13}
\end{align*}
\]

where \( j = 1, 2, 3, \cdots , n/2 - 1 \) is the index, and \( \psi_n = -i\psi_{n-1} \). The right edge state \( |\psi_R\rangle \), localizes at the right boundary and has eigen energy \( E_R(k_x) = t \sin k_x \). We can consider \( \psi_n = 1 \), and the recursion relation for the wave functions of the right edge state \( |\psi_R\rangle \) is

\[
\begin{align*}
\psi_{n-(2j-1)} &= -i\psi_{n-(2j-2)}, \\
\psi_{n-2j} &= \left(1 - (2\gamma)/t - (m + t \cos k_x)/t\right)\psi_{n-(2j-2)}, \tag{14}
\end{align*}
\]

where \( j = 1, 2, 3, \cdots , n/2 - 1 \) is the index, and \( \psi_1 = -i\psi_2 \). Notably, the edge state energy is independent of the coupling \( m \) and the non-Hermiticity \( \gamma \) although both affect the wave functions. The edge states under OBC in
the $y$ direction in different topological phases are depicted in Figs. 8(a)-8(c). Figure 8(a) presents the edge states in the $C = 1$ phase, as illustrated in Fig. 8(a); Fig. 8(b) represents the edge states in the gapless phase, as illustrated in Fig. 8(c); Fig. 8(c) represents the in-gap edge states in the $C = 0$ phase, as illustrated in Fig. 8(e). The green region ($C = 0$) with in-gap edge states is a novel phase induced by non-Hermiticity.

For the system under OBC in the $x$ direction, the left edge state localizes at the left boundary and has eigen energy $E_L(k_y) = -t \sin(k_y/2)$. The wave functions of the left edge state $|\psi_L\rangle$ satisfies the recursion relation

$$
\begin{align*}
\psi_{j+1} &= \frac{i\gamma}{t} \psi_{j-1} - \frac{m}{m/t + \cos(k_y/2)} \psi_{j-3}, \\
\psi_{j+3} &= -\frac{m}{m/t + \cos(k_y/2)} \psi_{j-1} - \frac{i\gamma}{t} \psi_{j-3}, \\
\psi_{j+2} &= \psi_{j+1} e^{i\theta}, \\
\psi_{j+4} &= -\psi_{j+3} e^{i\theta},
\end{align*}
$$

where $j = 1, 2, 3, \ldots, n/4 - 1$ is the index, and $\psi_1 = 1$, $\psi_2 = e^{i\theta}$, $\psi_3 = -\psi_1 e^{i\theta}$ with $\sin \theta = \sin(k_y/2)$, and $\cos \theta = -\cos(k_y/2)$. The right edge state, localizes at the right boundary and has eigen energy $E_R(k_y) = t \sin(k_y/2)$. The recursion relation for the wave functions of the right edge state $|\psi_R\rangle$ is

$$
\begin{align*}
\psi_{n-j} &= \frac{i\gamma}{t} \psi_{n-(j+2)} - \frac{m}{m/t + \cos(k_y/2)} \psi_{n-(j+4)}, \\
\psi_{n-(j+2)} &= -\frac{m}{m/t + \cos(k_y/2)} \psi_{n-(j+4)} - \frac{i\gamma}{t} \psi_{n-(j+6)}, \\
\psi_{n-(j+1)} &= \psi_{n-j} e^{i\theta}, \\
\psi_{n-(j+3)} &= -\psi_{n-(j+2)} e^{i\theta},
\end{align*}
$$

FIG. 8. Edge states for the quasi-1D lattice in Fig. 6 under OBC. The set momentum in the direction under PBC is marked inside. The parameters are identical with those chosen in Fig. 7. $\gamma = 1/2$ in (a), (c), (d); $\gamma = 2$ in (b); and $\gamma = 3/2$ in (e). Other parameters are $m = t = 1$ except for $m = 0$, $t = 1$ in (c).

V. DISCUSSION

**1D projection of the Chern insulator.** The quasi-1D Creutz ladder [Fig. 8(b)] changes into a 1D RM ladder with asymmetric intra-ladder leg coupling at $\lambda \neq \pm t$. (b) can be regarded as a 1D RM chain of (a) with symmetric long-range coupling. $-t \sin k_x$ and $t \sin k_x$ are the on-site real potentials for the upper (light gray) and lower (dark gray) sites, respectively. The non-Hermitian element is the asymmetric coupling $\mu \nu$.

![Diagram](image_url)

where $j = 1, 2, 3, \ldots, n/4 - 1$ is the index, and $\psi_n = 1$, $\psi_{n-1} = e^{i\theta}$, $\psi_{n-2} = -i\gamma/t/[m/t + \cos(k_y/2)]$, and $\psi_{n-3} = -\psi_{n-2} e^{i\theta}$ with $\sin \theta = \sin(k_y/2)$, and $\cos \theta = -\cos(k_y/2)$. The edge states under OBC in the $x$ direction in different topological phases are depicted in Figs. 8(d) and 8(e). Figure 8(d) represents the edge states in the $C = 1$ phase, as illustrated in Fig. 8(a); Fig. 8(e) represents the edge states in the gapless phase, as illustrated in Fig. 8(b).
key point for the validity of conventional bulk-boundary correspondence.

Experimental realization. The non-Hermitian Chern insulator can be simulated by dissipative ultracold atoms in an optical lattice with a synthetic magnetic field and the spin-orbital coupling [176,177]. In addition, the non-Hermitian Chern insulator can be implemented in optical and photonic systems such as coupled waveguide and coupled resonator lattices [178,179], where optical dissipation and radiation ubiquitously exist. Instead of incorporating a balanced gain and loss, introducing different dissipations in different sublattices facilitates realization of passive non-Hermitian topological systems in experiment. It is convenient to induce losses by sticking additional absorption materials. In Ref. [129], proposed realization of a coupled resonator optical waveguide lattice of the non-Hermitian Creutz ladder with gain and loss; this proposal is directly applicable realizing the inversion symmetric non-Hermitian Chern insulator investigated in this study by coupling the Creutz ladders together and adding the non-Hermiticity alternately in the $x$ and $y$ directions.

VI. SUMMARY

In summary, we investigated an inversion symmetric 2D non-Hermitian Chern insulator with balanced gain and loss in $x$ and $y$ directions and found that the conventional bulk-boundary correspondence holds. The bulk topology determines the phase diagram and accurately predicts the topological phase transition and the (non)existence of topological edge states for the system under OBC. The helical edge states exist in the phase with nonzero Chern number for the system under OBC in both directions. By contrast, non-Hermiticity can vary the system topology and destroys (create) helical edge states. Non-Hermiticity creates topological gapless phase, where the helical edge states exist in the inversion symmetric non-Hermitian Chern insulator under OBC in only one direction. The winding number associated with the vector field of the average values of Pauli matrices predicts the edge states in the gapless phase. Furthermore, non-Hermiticity creates a novel topological phase with zero Chern number, in which a pair of topologically protected in-gap helical edge states are found, protected by the 2D Zak phase associated fractional polarization; this feature differs from the trivial phase with zero Chern number and without edge states. Our findings provide insights into symmetry-protected non-Hermitian topological insulators.

APPENDIX A: ENERGY BAND OF THE TWO-BAND EQUIVALENT HAMILTONIAN

We show the energy band of the equivalent two-band Bloch Hamiltonian $h(k)$ in Fig. 19 as the comparison with the energy bands of the four-band Bloch Hamiltonian $\mathcal{H}(k)$ depicted in Fig. 2. Three typical phases are presented. In Fig. 10(a), we show the topologically nontrivial phase with $C = 1$ to compare with the energy bands depicted in Fig. 2(a). In Fig. 10(b), we show the gapless phase to compare with the energy bands depicted in Fig. 2(d). In Fig. 10(c), we show the topologically trivial phase with $C = 0$ to compare with the energy bands depicted in Fig. 2(f).

APPENDIX B: ROBUSTNESS OF IN-GAP EDGE STATE

We consider the 2D Chern insulator under OBC in the $y$ direction as schematically illustrated in Fig. 6(b). The in-gap edge states are robust to the inversion symmetric perturbations. We demonstrate the robustness to the inversion symmetric perturbations in the form of on-site potentials (detunings), as well as gain and loss, respectively. The inversion symmetry requires $V_{a_j} = V_{d_j}$ and $V_{b_j} = V_{c_j}$; the pseudo-Hermiticity holds under $V_{a} + V_{b} = 0$ and $V_{c} + V_{d} = 0$. The energy spectra of the lattice under perturbations are depicted in Fig. 11 for the comparison with the energy spectrum in the upper panel of Fig. 7(e). In Fig. 11(a), the perturbations are the inversion symmetric on-site potentials $V_{a} = V_{d} = -V_{b} = -V_{c} = 0.2R_j$, where $R_j$ is a random real number within the region $[0, 1]$ for each unit cell.
In both cases of Fig. 11, the in-gap edge state energies are unchanged and remain in the bandgap, being robust to the inversion symmetric perturbations.
