Abstract

Logistic Bandits have recently undergone careful scrutiny by virtue of their combined theoretical and practical relevance. This research effort delivered statistically efficient algorithms, improving the regret of previous strategies by exponentially large factors. Such algorithms are however strikingly costly as they require $\Omega(t)$ operations at each round.

On the other hand, a different line of research focused on computational efficiency ($O(1)$ per-round cost), but at the cost of letting go of the aforementioned exponential improvements. Obtaining the best of both worlds is unfortunately not a matter of marrying both approaches. Instead we introduce a new learning procedure for Logistic Bandits. It yields confidence sets which sufficient statistics can be easily maintained online without sacrificing statistical tightness. Combined with efficient planning mechanisms we design fast algorithms which regret performance still match the problem-dependent lower-bound of Abeille et al. (2021). To the best of our knowledge, those are the first Logistic Bandit algorithms that simultaneously enjoy statistical and computational efficiency.

1 INTRODUCTION

Logistic Bandit. The Logistic Bandit (LogB) framework describes sequential decision making problems in which an agent receives structured binary bandit feedback for her decisions. This namely allows to model numerous real-world situations where actions are evaluated by success/failure feedback (e.g. click/no-click in ad-recommendation problems). From a theoretical standpoint, the LogB framework allows a neat and concise study of the interactions between non-linearity and the exploration/exploitation trade-off. Recent research efforts on this front were conducted by Faury et al. (2020); Abeille et al. (2021); Jun et al. (2021), relying on improved confidence sets for the design and analysis of regret-minimizing LogB algorithms. This has led to significant improvement over the seminal work of Filippi et al. (2010), deflating the regret bounds by exponentially large factors. Their approach testifies of the importance of a careful handling of non-linearity in order to achieve optimal performances (i.e matching the regret lower-bound from Abeille et al. (2021, Theorem 2)). From a learning-theoretic standpoint, this line of work brings the understanding of LogB almost to a tie with the Linear Bandit (LinB). It highlights that some highly non-linear LogB instances are easier to solve (in some sense) than their LinB counterparts and brings forward algorithms with largely improved practical performances (see Abeille et al. (2021, Section H)).

Limitations. A severe drawback of those improved LogB algorithms resides in their tremendous computational cost. For instance, the OFULog-r algorithm of Abeille et al. (2021) requires to maintain batch maximum-likelihood estimators (which cannot be updated recursively) and to solve at every round expensive convex programs. The computational hardness of those tasks (respectively related to the learning and planning mechanisms of the algorithm) largely exceeds their LinB counterparts and lead to a painfully slow algorithm - prohibitively so for situations where decisions must be made on the fly. As a result, statistically efficient yet fast LogB algorithms are still missing - which is the topic of this paper.

Main Contributions. Our main contribution is (1) a new learning procedure for LogB. It yields (2) a new confidence set which sufficient statistics can be maintained at each round with $\tilde{O}(1)$ operations, without sacrificing statistical tightness. Furthermore (3) the shape of this set enables the deployment of efficient planning strategies as a plug-in. This enables the design of computationally efficient algorithms whose regret guarantees match the lower-bound of Abeille et al. (2021). To the best of our knowledge, those LogB algorithms are the first to enjoy both statistical and
compositional efficiency simultaneously. We summarize our contributions in Table 1.

**Organization.** We formally introduce the learning problem in Section 2 and discuss previous works, their limitations and remaining challenges. In Section 3 we describe our new estimation method, coined Efficient Local Learning for Logistic Bandits (ECLLog). We then analyze an optimistic algorithm leveraging this procedure and claim that it enjoys the same regret guarantees obtained by Abeille et al. (2021) while being critically less computationally hungry. We exhibit the main technical arguments needed to obtain this result and discuss potential extensions as well as limitations of our approach. In Section 4 we detail a variant of our algorithm, more complex but better suited for deployment in real-life situations. We provide similar guarantees for this algorithm and illustrate its good practical behavior with numerical simulations.

## 2 PRELIMINARIES

### 2.1 The Learning Problem

**Setting.** The LogB framework describes a repeated game between an agent and her environment. At each round, the agent selects an action (a vector in some Euclidean space) and receives a binary, Bernoulli distributed reward. More precisely, given an arm-set\(^1\) \(A \subset \mathbb{R}^d\) the agent plays at each round \(t\) an arm \(a_t \in A\) and receives a stochastic reward \(r_{t+1}\) following:

\[
r_{t+1} \sim \text{Bernoulli}(\mu(a_t^T \theta_*)),
\]

where \(\mu(z) = (1 + \exp(-z))^{-1}\) is the logistic function. The parameter \(\theta_*\) is unknown to the agent. We will work under the following assumption, standard for the study of LogB.

**Assumption 1 (Bounded Decision Set).** For any \(a \in A\) we have \(\|a\| \leq 1\). Also, \(\|\theta_*\| \leq S\) where \(S\) is known.

Denote \(a_* := \arg \max_{a \in A} a^T \theta_*\) the best action in hindsight. The goal of the agent is to minimize her cumulative pseudo-regret up to time \(T\):

\[
\text{Regret}(T) := T \mu(a_*^T \theta_*) - \sum_{t=1}^{T} \mu(a_t^T \theta_*).
\]

**Reward Sensitivity.** Central to the analysis of LogB is the inverse minimal reward sensitivity \(\kappa\). This problem-dependent constant is defined as:

\[
\kappa := 1 / \min_{a \in A} \min_{\|\theta\| \leq S} \mu(a^T \theta).
\]

\(^1\)For the sake of exposition we here only consider the static arm-set case. As later detailed, our results also apply to time-varying arm-sets and contextual settings.

Briefly, \(\kappa\) measures the level of non-linearity of the reward signal, usually high in LogB problems. As such \(\kappa\) is typically very large (numerically) even for reasonable configurations. We refer the reader to Faury et al. (2020, Section 2) for a detailed discussion on the importance of this quantity.

**Additional Notations.** For any \(t \geq 1\) we denote the \(\mathcal{F}_t := \sigma(a_1, r_2, \ldots, a_t)\) the \(\sigma\)-algebra encoding the information acquired after playing \(a_t\) and before observing \(r_{t+1}\). Throughout the paper time indexes reflect the measurability w.r.t \(\mathcal{F}_t\) (for example, \(a_t\) is \(\mathcal{F}_t\)-measurable but not \(\mathcal{F}_{t+1}\)-measurable). For any pair \((x, y) \in \mathbb{R} \times \{0, 1\}\) we define:

\[
\ell(x, y) = -y \log \mu(x) - (1 - y) \log(1 - \mu(x)),
\]

and the log-loss associated with the pair \((a_t, r_{t+1})\) writes \(\ell_{t+1}(\theta) := \ell(a_t^T \theta, r_{t+1})\). Given a compact set \(\Theta \subset \mathbb{R}^d\) its diameter under the arm-set \(A\) is:

\[
\text{diam}_A(\Theta) = \max_{a \in A} \max_{\theta_1, \theta_2} |a^T(\theta_1 - \theta_2)|.
\]

We will use throughout the paper the symbol \(\mathcal{C}\) to denote universal constants (i.e independent of \(S, \kappa, d\) or \(T\)) which exact value can vary at each occurrence. Similarly, we use the generic notation \(\gamma_\delta\) to denote various slowly growing functions - more precisely such that \(\gamma_\delta(\delta) = \mathcal{C}\text{poly}(S)d \log(t/\delta)\). The exact values for the different occurrences of such functions are carefully reported in the supplementary materials.

### 2.2 Previous Work, Limitations and Remaining Challenges

Being a member of the Generalized Linear Bandit family, the first algorithm for LogB was given by Filippi et al. (2010). Their algorithm enjoys a regret scaling as \(\tilde{O}(kd\sqrt{T})\) - which although tight in \(d\) and \(T\), suffers from a prohibitive dependency in \(\kappa\). Further, it is computationally inefficient as it requires the computation of a batch estimator for \(\theta_*\) at each round (see Appendix E.2 for a detailed discussion). This efficiency issue was fixed by Zhang et al. (2016); Jun et al. (2017); Ding et al. (2021) who proposed fully online estimation procedures. Their approaches however still suffer from detrimental dependencies in \(\kappa\).

**Statistical Optimality.** The \(\kappa\) dependency was trimmed by Faury et al. (2020) who introduced an algorithm enjoying \(\tilde{O}(d\sqrt{T})\) regret. Their approach defers the effect of non-linearity (embodied by \(\kappa\)) to a second-order term in the regret, dominated for large values of \(T\). Similar results were also achieved by Dong et al. (2019), but only for the Bayesian regret. From a statistical viewpoint the story was closed by Abeille et al. (2021) who proved a \(\Omega(d \sqrt{\mu(a_*^T \theta)T})\) regret lower-bound and matching regret upper-bounds (up
to logarithmic factors) for their algorithm OFULog-r. Given the typical scalings of $\kappa \propto \exp(\|\theta_i\|)$ and $\bar{\mu}(\theta_i) \propto \exp(-\|\theta_i\|)$ this deflates the regret of previous approaches by exponentially large factors.

**Computational Cost.** Albeit statistically optimal, the algorithms proposed by Abeille et al. (2021) are strikingly computationally demanding and consequently prohibitively slow for practical situations. After inspection, two main computational bottlenecks of their approach emerge from their learning and planning mechanisms. From the learning side, they construct confidence regions of the form:

$$\left\{ \theta, \|\theta - \hat{\theta}_i\|^2_{H_{i-1}(\theta)} \leq \gamma_i(\delta) \right\},$$  

(2)

where $\hat{\theta}_i = \arg\min_{\theta} \sum_{s=1}^{t-1} \ell_{s+1}(\theta) + \lambda\|\theta\|^2$ and

$$H_i(\theta) = \sum_{s=1}^{t} \bar{\mu}(\theta_s) a_s a_s^T + \lambda I_d .$$

Those sufficient statistics are expensive to compute as both require a linear pass (at least) on the data. Note that simply testing whether a point lies in this set is costly - it requires $\Omega(t)$ operations. The planning mechanism which leverages this confidence region suffers from this downside; to find an optimistic arm it must solve one expensive convex program per arm at every round. This program involves the complete log-loss, which evaluation also takes $\Omega(t)$ operations. Furthermore, bypassing optimism through randomized exploration (e.g. Thompson Sampling) is particularly challenging as the results of Agrawal and Goyal (2013); Abeille and Lazaric (2017) do not apply to non-ellipsoidal confidence regions.

**Challenges.** Our goal is to develop an efficient algorithm (i.e with reduced per-round computational cost) which still enjoys statistical optimality (i.e matches the lower-bound of Abeille et al. (2021)). In light of the previous discussion, a crucial step is to derive an alternative to the confidence set from Equation (2) which sufficient statistics can be updated at little cost. This must be done without sacrificing the confidence set’s appreciation of the effective reward sensitivity, captured by the matrix $H_i(\theta)$ and central for optimal performance. In other words, we seek to develop an efficient estimation procedure that captures the local effects of non-linearity. This rules out merging the refined concentration tools of Faury et al. (2020) with the online approaches of Zhang et al. (2016); Jun et al. (2017) which explicitly ressorts to global quantities (e.g. $\kappa$) in their estimation routines.

### 3 MAIN RESULTS

In this section we present our approach to address the aforementioned challenges. We introduce OFU-ECOLog, an optimistic algorithm whose pseudo-code is provided in Algorithm 1. It is built on top on three building blocks; (1) a short warm-up phase (forced-exploration) of size $\tau$ described in Procedure 1, (2) the ECOLog estimation procedure described in Procedure 2 and (3) an optimistic planning mechanism.

We provide in Section 3.1 theoretical guarantees for the regret of OFU-ECOLog (Theorem 1) and quantify its per-round computational cost (Proposition 1). It demonstrates that OFU-ECOLog enjoys both statistical and computational efficiency.

Each building block (1-3) and their specific roles are detailed in subsequent sections. Section 3.2 is concerned with the initial forced-exploration phase and its length $\tau$. Section 3.3 details the estimation procedure ECOLog and the confidence region it induces. Section 3.4 details the efficient deployment of the optimistic exploration strategy and describes the extension of OFU-ECOLog to TS-ECOLog, where optimism is replaced with randomization.
Jointly Efficient and Optimal Algorithms for Logistic Bandits

Algorithm 1 OFU-ECLog

input: failure level $\delta$, warm-up length $\tau$.

Set $\Theta \leftarrow \text{WarmUp}(\tau)$ (see Procedure 1).

Initialize $\theta_{t+1} \in \Theta$, $W_{t+1} \leftarrow I_d$ and $C_{t+1}(\delta) \leftarrow \Theta$.

for $t \geq \tau + 1$ do

Play $a_t \in \text{arg max}_{a \in A} \max_{\theta \in C_t(\delta)} a^T \theta$.

Observe reward $r_{t+1}$, construct loss $\ell_{t+1}(\theta) = \ell(a_t^T \theta, r_{t+1})$.

Compute $(\theta_{t+1}, W_{t+1}) \leftarrow \text{ECOLog}(1/t, \Theta, \ell_t, \theta_t)$ (see Procedure 2).

Compute $C_{t+1}(\delta) \leftarrow \left\{ \|\theta - \hat{\theta}_{t+1}\|_W^2 \leq \gamma_{t}(\delta) \right\}$.

end for

Procedure 1 WarmUp

input: length $\tau$.

Set $\lambda \leftarrow \gamma_{\tau}(\delta)$, initialize $V_0 \leftarrow \lambda I_d$.

for $t \in [1, \tau]$ do

Play $a_t \in \text{arg max}_a \|a\|_{V_{t-1}}$, observe $r_{t+1}$.

Update $V_t \leftarrow V_{t-1} + a_t a_t^T / \kappa$.

end for

Compute $\hat{\theta}_{t+1} \leftarrow \text{arg min}_\theta \sum_{s=1}^t \ell_s(\theta) + \lambda \|\theta\|^2$.

output: $\Theta = \left\{ \theta, \|\theta - \hat{\theta}_{t+1}\|_V^2 \leq \gamma_{\tau}(\delta) \right\}$.

Procedure 2 ECOLog

input: accuracy $\varepsilon$, convex set $\Theta$, $\ell_{t+1}$, $W_t$, $\theta_t$.

Compute $D \leftarrow \text{diam}_A(\Theta)$, set $\eta \leftarrow (2 + D)^{-1}$.

Solve to precision $\varepsilon$:

$$\hat{\theta}_{t+1} = \text{arg min}_{\theta \in \Theta} \left[ \eta \|\theta - \theta_t\|_W^2 + \ell_{t+1}(\theta) \right].$$

Update $W_{t+1} \leftarrow W_t + \hat{\mu}(a_t^T \theta_{t+1}) a_t a_t^T$.

output: $\theta_{t+1}, W_{t+1}$

3.1 Statistical and Computational Efficiency

We claim the following result, which proof is deferred to Appendix D.1.

Theorem 1 (Regret Bound). Let $\delta \in (0, 1]$. Setting $\tau = \kappa S^6 \gamma_T(\delta)^2$ ensures the regret of OFU-ECLog$(\delta, \tau)$ satisfies with probability at least $1 - 2\delta$:

$$\text{Regret}(T) \leq C S d \sqrt{T \mu(\theta_\kappa^T) \log(T/\delta) + C S^6 \kappa^2 d^2 \log(T/\delta)^2}.$$

As promised the dominating term in OFU-ECLog’s regret-bound matches the lower-bound of Abeille et al. (2021) and scales with the reward sensitivity at the best action $a_\kappa$. Further, the second-order term identically matches its counterpart from previous work in its scaling w.r.t $d$, $T$ and $\kappa$. This establishes the statistical efficiency and we now move up to the computational cost. For this, we claim the following bound on the complexity of OFU-ECLog.

Proposition 1 (Computational Cost). Let $|A| = K < \infty$. Each round $t$ of OFU-ECLog can be completed within $O(K d^2 + d^2 \log(t)^2)$ operations.

The proof is deferred to Appendix E.1. This result mainly relies on the fact that the ECOLog routine (Procedure 2) solves convex programs that are cheap (i.e. for which gradients are inexpensive to compute) and that can be efficiently preconditioned. Furthermore OFU-ECLog leverages ellipsoidal confidence sets, for which optimism can be efficiently enforced (at least for finite arm-sets). This fulfills our promise of computational efficiency.

3.2 Warm-Up

One of the main challenge to avoid prohibitive exponential dependencies in LogB is to tightly control the reward sensitivity across $A \times \Theta$ - that is, without resorting to global problem-dependent constants (e.g. $\kappa$). Following Faury et al. (2020) a first useful step in that direction is to leverage the self-concordance property of the logistic function. It ensures that for any $a \in A$:

$$\forall \theta_1, \theta_2 \in \Theta, \mu(a^T \theta_1) \leq \mu(a^T \theta_2) \exp(\text{diam}_A(\theta)).$$  (3)

The role of the warm-up phase is to identify a set $\Theta$ containing $\theta_\kappa$ (with high probability) and which diameter is a constant, independent of problem-dependent quantities (e.g. $\|\theta_\kappa\|$ or $S$). The warm-up mechanism described in Procedure 1 constructs such a set $\Theta$ which diameter is controlled through the length $\tau$ of this forced-exploration phase. In particular, we show that if $\tau \propto \kappa$ (Proposition 5 in the appendix):

$$\text{diam}_A(\Theta) \leq 1 \text{ for } \Theta \leftarrow \text{WarmUp}(\tau).$$  (4)

Combining Equations (3) and (4) allows to control the reward sensitivity across the set $\Theta$ at little cost (i.e independent of problem-dependent constants). Theoret-
ically speaking, the regret incurred during the warm-up phase forms a second-order term, dominated in the overall regret bound. From a practical perspective however, resorting to forced-exploration is inconvenient - a downside we address in Section 4.

Remark (Optimal Design). There exists alternatives warm-up strategies which ensures similar guarantees - see for instance Jun et al. (2021) for a solution based on optimal design. It involves more complex mechanisms to reduce the length $\tau$ - we stick here to a simple strategy for the sake of exposition.

### 3.3 Efficient Local Learning

We now describe ECOLog, a new estimation routine summarized in Procedure 2 which is at the core of the online construction of tight confidence sets. It operates on the convex set $\Theta$ returned by the warm-up procedure. It maintains estimates $\{\theta_t\}_t$ of $\theta_\star$ following the update rule:

\[
\theta_{t+1} = \arg \min_{\theta \in \Theta} \left[ \eta \|\theta - \theta_t\|^2_{\mathbf{W}_t} + \ell_{t+1}(\theta) \right],
\]  
(5)

where $\mathbf{W}_t = \sum_{s=1}^{t-1} \mu(a_s^T \theta_{s+1})a_s a_s^T + \lambda I_d$.

The learning rate $\eta$ is tied to the diameter $\text{diam}_A(\Theta)$ of the decision set $A \times \Theta$. After round $t$, the next estimate $\theta_{t+1}$ minimizes an approximation of the true cumulative log-loss $\sum_{s=1}^{t} \ell_{s+1}(\theta)$ that is decomposed in two terms. The first consists in a quadratic proxy for the past losses constructed through the sequence $\{\theta_s\}_{s \leq t}$. It is designed to incorporate the information acquired so far in the update since:

\[
\arg \min_{\theta} \sum_{s=1}^{t-1} \ell_{s+1}(\theta) \approx \arg \min_{\theta} \|\theta - \theta_t\|^2_{\mathbf{W}_t}.
\]

On the other hand, the second term is the instantaneous log-loss $\ell_{t+1}(\theta)$ which accounts for the novel information of the pair $(a_t, r_{t+1})$. The motivation behind the overall structure of the update is the following: while the cumulative log-loss is strongly convex and can therefore be well approximated by a quadratic function, the instantaneous loss $\ell_{t+1}$ has flat tails which cannot be captured by a quadratic shape.

Remark (Comparison with ONS). While at first glance it resembles the Online Newton Step (ONS) mechanisms used by Zhang et al. (2016); Jun et al. (2017) there are two important differences. First, the update is driven by the matrix $\mathbf{W}_t$ which relies on the estimated reward sensitivity, and not on its worst-case alternative $\kappa$. Second, we do not rely on (potentially loose) approximations for $\ell_{t+1}$. This rules out having access to a closed-form for $\theta_{t+1}$.

Since the solution of Equation (5) does not admit a closed-form expression, one can only solve it up to an $\varepsilon$ accuracy (e.g. with projected gradient descent). Formally, we compute estimators $\theta'_{t+1}$ such that $\|\theta'_{t+1} - \theta_{t+1}\| \leq \varepsilon$. The following statement guarantees that this can be done at little cost.

**Proposition 2** (Computational Cost). Running ECOLog up to $\varepsilon > 0$ accuracy requires $O(d^2 \log(1/\varepsilon)^2)$ operations.

For the sake of exposition, we ignore optimization errors in the following since $\varepsilon$ can be arbitrarily small. The induced errors and their propagation are addressed in formal proofs in the supplementary.

Finally, the use of ECOLog at each round within Algorithm 1 yields a sequence $\{\theta_t, \mathbf{W}_t\}_t$ associated with the sets:

\[
\mathcal{C}_t(\delta) := \left\{ \theta : \|\theta - \theta_t\|^2_{\mathbf{W}_t} \leq \gamma_t(\delta) \right\},
\]

which are confidence regions for $\theta_\star$.

**Proposition 3** (Confidence Set). Under the conditions of Theorem 1:

\[
\mathbb{P}(\forall t, \theta_\star \in \mathcal{C}_t(\delta)) \geq 1 - \delta.
\]

Proposition 3 emulates the original concentration results of Faury et al. (2020) (see Equation (2)). The matrix $\mathbf{W}_t$ stands as an on-policy proxy for the “correct” concentration metric $\mathbf{W}_t(\theta_\star)$. This ultimately preserves statistical tightness (Theorem 1) but with sufficient statistics that are now updated online.

**Proof Sketch.** We provide here the key technical arguments behind the derivation of Proposition 3. It is inspired and shares close connections with the work of Jézéquel et al. (2020) - which was conducted for an Online Convex Optimization setting.

A crucial ingredient for our analysis is a local quadratic lower-bound\(^2\) for the logistic loss, stating that for any $\theta \in \Theta$:

\[
\ell_{t+1}(\theta_\star) \gtrsim \ell_{t+1}(\theta_\star) + \nabla \ell_{t+1}(\theta_\star)^T (\theta_\star - \theta) + \mu(a_t^T \theta)(a_t^T (\theta_\star - \theta))^2.
\]

Notice how the above does not depend on any global quantities (e.g. $S$ or $\|\theta_\star\|$). It allows to tie the parameters uncertainty $\|\theta_\star - \theta_{t+1}\|^2_{\mathbf{W}_{t+1}}$ to the excess cumulative loss in $\{\theta_{s+1}\}_s$. Indeed algebraic manipulations lead to:

\[
\|\theta_\star - \theta_{t+1}\|^2_{\mathbf{W}_{t+1}} \lesssim \sum_{s=1}^{t} \ell_{s+1}(\theta_\star) - \ell_{s+1}(\theta_{s+1}).
\]

\(^2\)Similar bounds appear in Jézéquel et al. (2020); Abeille et al. (2021) but are used for different purposes.
We are therefore left to bound the r.h.s. To do so we introduce an intermediary parameter:
\[ \tilde{\theta}_s = \arg\min_{\theta} \| \theta - \theta_s \|_{W_s}^2 + \ell(a_s^T \theta, 0) + \ell(a_s^T \theta, 1), \]
and decompose the sum to control as follows:
\[ \sum_{s=1}^{t} \ell_{s+1}(\theta_s) - \ell_{s+1}(\tilde{\theta}_s) + \sum_{s=1}^{t} \ell_{s+1}(\tilde{\theta}_s) - \ell_{s+1}(\theta_{s+1}). \]  
(6)

The parameter \( \tilde{\theta}_s \) is a \( F_s \)-measurable version of \( \theta_{s+1} \), regularized in the last direction \( a_s \) by two logistic losses fitting antipodal rewards \( (r_{s+1} = 0 \text{ and } 1) \). The first term in Equation (6) is tied to the stochastic nature of the observations and is bounded using the concentration inequality of Faury et al. (2020, Theorem 1). With probability at least \( 1 - \delta \),
\[ \sum_{s=1}^{t} \ell_{s+1}(\theta_s) - \ell_{s+1}(\tilde{\theta}_s) \lesssim \log(t/\delta). \]

Bounding the second term requires quantifying the deviation between \( \theta_{s+1} \) and its \( F_s \)-measurable counterpart \( \tilde{\theta}_s \). Leveraging convexity leads to the sequence of inequalities:
\[ \sum_{s=1}^{t} \ell_{s+1}(\tilde{\theta}_s) - \ell_{s+1}(\theta_{s+1}) \leq \sum_{s=1}^{t} \mu(a_s^T \tilde{\theta}_s) \| a_s \|^2_{W_{s+1}} \lesssim \sum_{s=1}^{t} \mu(a_s^T \theta_{s+1}) \| a_s \|^2_{W_{s+1}} \lesssim d \log(t). \]

The second inequality is obtained by relating the reward sensitivities \( \mu(a_s^T \tilde{\theta}_s) \) and \( \mu(a_s^T \theta_{s+1}) \). Both are comparable thanks to the warm-up procedure. Indeed from Equations (3) and (4),
\[ \mu(a_s^T \tilde{\theta}_s) \leq \exp(\text{diam}_A(\Theta)) \mu(a_s^T \theta_{s+1}) \lesssim \mu(a_s^T \theta_{s+1}). \]  
(7)

The last inequality directly follows from the Elliptical Potential Lemma (see Lemma 9).

**Remark** (Warm-Up and Online Newton Step). It is natural to wonder whether the ONS-like approaches of Zhang et al. (2016); Jun et al. (2017) could also benefit from the refined parameter set returned by the warm-up procedure. As detailed in Appendix B.3 this is not the case. Their respective methods hard-code global quantities within their updates steps (such as the minimum curvature of the log-loss, or the exp-concavity constant). Those are related to \( \kappa \) and cannot be removed even when operating close to \( \theta_\star \).

### 3.4 Exploration Strategy

**Optimistic Exploration.** OFU-ECOLog builds on \( C_\kappa(\delta) \) (the confidence set of Proposition 3) to find an optimistic arm. Formally, it prescribes playing:
\[ a_t \in \arg\max_{a \in A} \max_{\theta \in C_\kappa(\delta)} a^T \theta. \]

A solution for this problem might be expensive to compute in general. However, the ellipsoidal nature of \( C_\kappa(\delta) \) may simplify this task as it allows for an equivalent definition of \( a_t \) as:
\[ a_t \in \arg\max_{a \in A} a^T \theta_t + \sqrt{\kappa(t)} \| a \|_{W_{t-1}}. \]

For finite arm-sets (\(|A| = K < +\infty|A| \)) this program can be solved by enumerating over the arms - bringing the total cost of the optimistic planning to \( O(d^2 K) \).

**Thompson-Sampling extension.** The shape of \( C_{\kappa+1}(\delta) \) also enables the use of randomized exploration mechanisms in a principled fashion. For instance, Thompson Sampling (TS) replaces the burden to find an optimistic parameter by sampling in slightly inflated confidence sets (see Abeille and Lazaric (2017)). It is often preferred in practical applications for its simplicity and good empirical performances. It also allows to deal with infinite arm-sets, whenever an oracle for computing \( a_s(\theta) = \arg\max_{a \in A} a^T \theta \) is cheaply available for any \( \theta \) (e.g. when the active space is the unit-ball \( B_d \)). We introduce TS-ECOLog in Appendix D.2, a TS version of OFU-ECOLog. It enjoys similar regret bounds, but inflated by a \( \sqrt{d} \) factor (as in the LinB case). The algorithm displays little conceptual novelty compared to its linear counterpart, but its analysis requires additional technical care to prove its statistical efficiency. Overall, this answers positively the question opened by Faury et al. (2020) about the extension of their approach to randomized strategies.

### 4 REMOVING THE WARM-UP

**Practical Limitations.** Despite being rather common in the Generalized Linear Bandit literature (e.g. (Li et al., 2017; Kveton et al., 2020; Jun et al., 2021; Ding et al., 2021)) the use of warm-up phases is concerning from a practical stand-point. Indeed (1) it hard-codes a forced-exploration regime lasting at least \( \kappa \) rounds at the beginning of any experiment. Given the typical scaling of \( \kappa \) in practical situations this implies that the algorithm selects actions at random for the first few thousand steps. While it only impacts low-order terms in the regret bound, it is problematic to suffer this price by design, even when not necessary (see Abeille et al. (2021, Section 4)). Furthermore, (2) generalizing warm-up phases to handle contextual arm-sets requires adopting strong distributional assumptions on the contexts - leaving out the case where an adversary picks context.
Algorithm 2 ada-OFU-ECOLog

**input:** failure level \( \delta \).

1. Initialize \( \Theta_1 = \{ \| \theta \| \leq S \}, C_1(\delta) \leftarrow \Theta_1, \theta_1 \in \Theta, W_1 \leftarrow I_d \) and \( \mathcal{H}_1 \leftarrow \emptyset \).
2. \( t \geq 1 \) do
   
   - Play \( a_t \in \arg \max_{a \in A} \max_{\theta \in C_t(\delta)} a^T \theta \), observe reward \( r_{t+1} \).
   - Compute the estimators \( \hat{\theta}_t^0, \hat{\theta}_t^1 \) (see Equation (8)) and \( \hat{\theta}_t \).
   - if \( \hat{\mu}(a_t^T \hat{\theta}_t) \leq 2 \hat{\mu}(a_t^T \hat{\theta}_t^0) \) and \( \hat{\mu}(a_t^T \hat{\theta}_t) \leq 2 \hat{\mu}(a_t^T \hat{\theta}_t^1) \) then
     
     - Form the loss \( C_{t+1}(\delta) \leftarrow \left\{ \| \theta - \theta_t+1 \|^2_{W_{t+1}} \leq \gamma_t(\delta) \right\} \).
   - else
     
     - Set \( \mathcal{H}_{t+1} \leftarrow \mathcal{H}_t \cup \{ a_t, r_{t+1} \} \) and compute \( \hat{\theta}_{t+1}^N = \arg \min_{\theta, r \in \mathcal{H}_{t+1}} \sum_{(a, r) \in \mathcal{H}_{t+1}} \ell(a^T \theta, r) + \gamma_t(\delta) \| \theta \|^2 \).
     
     - Update \( V_{t+1}^N \leftarrow \sum_{a \in \mathcal{H}_{t+1}} a a^T / \kappa + \gamma_t(\delta) I_d, \theta_{t+1} \leftarrow \theta_t \) and \( W_{t+1} \leftarrow W_t \).
   
   - Compute \( \Theta_{t+1} = \left\{ \| \theta - \hat{\theta}_{t+1}^N \|^2_{V_{t+1}^N} \leq \gamma_t(\delta) \right\} \).
   
3. end if
4. end for

**Data-Driven Alternative.** We relied so far on warm-up phases to isolate the different challenges (locality, efficiency, statistical tightness). We now switch gears and propose a refined approach which addresses the issues raised by forced-exploration - however at the cost of a more intricate algorithm. At the heart of this refinement lies a data-dependent version of our confidence set. This allows (1) the design an adaptive mechanism which preserves statistical efficiency while ultimately removing the need for forced-exploration. Furthermore, it (2) extends the regret bound derived in Section 3 to the contextual case, without requiring any distributional assumptions on the exogenous contexts. To our knowledge, this is a first for approaches resorting to warm-ups.

4.1 An Adaptive Approach

**Intuition.** As highlighted by the proof sketch from Section 3.3, the warm-up phase allows to tightly control the radius of \( C_t(\delta) \). More precisely, it constructs a small admissible set \( \Theta \) that constrains the reward sensitivities \( \hat{\mu}(a_s^T \theta) \) and \( \hat{\mu}(a_s^T \theta_{r+1}) \) to be comparable for all \( s \) (see Equation (7)).

A naive way to remove the need for enforcing this property a priori would be to reject on-the-fly points that don’t conform with the following condition:

\[
\hat{\mu}(a_s^T \theta) \leq 2 \hat{\mu}(a_s^T \theta_{r+1}) , \quad (C_0)
\]

This high-level idea is behind the design of our adaptive mechanism, detailed below.

**Adaptive Mechanism.** Given \( (a_s, r_{s+1}) \) if the associated \( \theta_{s+1} \) breaks \( (C_0) \) we do not use it to update our current estimate. Instead we leverage this information to ensure that \( (C_0) \) is more likely to hold in the future. We maintain \( \mathcal{H}_{s+1} = \{ a_t, r_{t+1} \}_{t \leq s} \) formed by pairs rejected up to round \( s \) and compute:

\[
\hat{\theta}_{s+1}^N = \arg \min_{\theta, r \in \mathcal{H}_{s+1}} \sum_{(a, r) \in \mathcal{H}_{s+1}} \ell(a^T \theta, r) + \gamma_s(\delta) \| \theta \|^2 ,
\]

and \( V_{s+1}^N = \sum_{a \in \mathcal{H}_{s+1}} a a^T / \kappa + \gamma_s(\delta) I_d \). We use this to build the parameter set:

\[
\Theta_{s+1} = \left\{ \theta, \| \theta - \hat{\theta}_{s+1}^N \|^2_{V_{s+1}^N} \leq \gamma_s(\delta) \right\} .
\]

We will use this convex set in the ECOLog procedure for subsequent rounds. As points are being added to \( \mathcal{H}_s \), the sequence of \( \{ \Theta_s \} \) deflates. The downstream estimates \( \{ \theta_{s+1}, \theta_{s} \} \) are therefore closer and \( (C_0) \) is more likely to hold. The key to assert the validity of this mechanism is to ensure that this sequential refinement does not occur too often.

**Technical Adjustment.** The idea presented above needs a slight technical refinement to bear a principled algorithm. \( (C_0) \) prescribes filtering the arm \( a_s \) according to \( \theta_{s+1} \), an \( \mathcal{F}_{s+1} \)-adapted quantities. This breaches concentration properties we need to prove low-regret. To circumvent this issue we fall back on an \( \mathcal{F}_r \)-adapted condition covering the potential values of \( \theta_{s+1} \) (depending on the realization of \( r_{s+1} \)). Let:

\[
\theta_s^* = \arg \min_{\theta \in \Theta_s} \left[ \eta \| \theta - \theta_s \|^2_{W_s} + \ell(a_s^T \theta, u) \right] , \quad (8)
\]

for \( u \in \{ 0, 1 \} \). Note that \( \theta_{s+1} \) is either \( \theta_0^* \) or \( \theta_1^* \). We replace \( (C_0) \) by the condition:

\[
\hat{\mu}(a_s^T \theta_s) \leq 2 \hat{\mu}(a_s^T \theta_s^*), \quad \forall u \in \{ 0, 1 \} . \quad (C_1)
\]

The algorithm ada-OFU-ECOLog presented in Algorithm 2 combines this adjustment with the aforementioned adaptive mechanism.
4.2 Theoretical Guarantees

Regret Bound. Thanks to its adaptivity, we can claim regret guarantees for ada-OFU-ECOLog in contextual settings - i.e. that holds for any sequence of time-varying arm-set \( \{A_t\}_{t \geq 1} \).

**Theorem 2.** Let \( \delta \in [0, 1) \). With probability at least \( 1 - \delta \) the regret of \( \text{ada-OFU-ECOLog}(\delta) \) satisfies:

\[
\text{Regret}(T) \leq \mathcal{C} S d \sqrt{\sum_{t=1}^{T} \hat{\mu}(a^*_t \theta^*_t) \log(T/\delta)} + \mathcal{C} S^6 \kappa d^2 \log(T/\delta)^2,
\]

where \( a^*_{t} = \arg \max_{a \in A_t} a^T \theta^* \).

The proof is deferred to Appendix D.3. This result establishes similar (although more general) regret guarantees than Theorem 1. The two bounds are identical for constant arm-sets (\( A_t \equiv A \)). In the contextual case, the leading term is \( \sqrt{T \sum_{t=1}^{T} \hat{\mu}(a^*_t \theta^*_t)/T} \), replacing the reward sensitivity at the optimal action by its on-trajectory average version.

Computational Cost. The per-round computational cost of Algorithm 2 is larger than \( \text{OFU-ECOLog} \) as it sometimes requires \( \mathcal{O}(|\mathcal{H}_t|) \) extra operations to compute \( \hat{\theta}^H \). The computational overhead is small as we can prove that \( |\mathcal{H}_t| \lesssim \kappa \).

**Proposition 4.** The per-round computational cost of Algorithm 2 is bounded by \( \mathcal{O}(\kappa + Kd^2 + d^2 \log(T)^2) \).

This extra computation is needed only when violating \( (C_1) \) which happens at most for \( \kappa \) rounds.

Adaptivity in Practice. Theorem 2 and Proposition 4 establish that hard-coding a warm-up-up phase can be avoided with little to no impact on the worst-case performance or computational cost. The adaptive nature of \( \text{ada-OFU-ECOLog} \) allows to enjoy stronger empirical performances in “nice” configurations. For instance, in all the numerical experiments that follow we found that the condition \( (C_1) \) was never triggered. In such cases, Algorithm 2 simply reduces to \( \text{OFU-ECOLog} \) without any forced-exploration. This is consistent with the analysis of Abeille et al. (2021, Section 4) which suggests that low-order \( \kappa \) dependencies (introduced here by the warm-up) can sometimes be avoided.

4.3 Numerical Simulations

The numerical illustrations presented in Figure 1 are consistent with our theoretical findings summarized in Table 1. As predicted, \( \text{ada-OFU-ECOLog} \) enjoys best-of-both-worlds properties by displaying small regret and small computational cost. Additional numerical illustrations for \( \text{LogB} \) instances of higher dimensions can be found in Appendix G.

The value of \( \kappa \) for \( \text{LogB} \) instances we consider are reasonable (comparable to real-life situations). Still, it precludes the use of warm-up phase in practice for it will simply last longer than the horizon we consider (for which \( \text{OFU-ECOLog} \) already exhibits asymptotic behavior). Note that this is even worse for other approaches using forced-exploration (Kveton et al., 2020; Ding et al., 2021) as their re-
pective warm-ups are typically even longer ($\propto \kappa^2$). Finally, we report results for an infinite arm-set for which our approach yields the only tractable algorithm enjoying statistical efficiency.

ORGANIZATION OF THE APPENDIX

This appendix is organized as follows:

• In Appendix A we recall important notations and introduce some central inequalities.
• In Appendix B we link the length of the warm-up to the diameter of the set $\Theta$ it returns.
• In Appendix C we prove that $C_t(\delta)$ is a confidence region for $\theta^\star$.
• In Appendix D we prove the different regret upper-bounds announced in the main paper.
• In Appendix E we detail the computational cost of the different approaches discussed in the main paper.
• In Appendix F we list some auxiliary results, needed for the analysis.
• In Appendix G we provide additional numerical illustrations.
A PRELIMINARIES

A.1 Notations

We detail below useful notations that will be used throughout the appendix. Below $T \in \mathbb{N}^+$, $U$ is a set, $\Theta \subset \mathbb{R}^d$ is a compact set, $a \in \mathcal{A}$, $r \in \{0, 1\}$ and $x, y \in \mathbb{R}^d$.

\begin{align*}
[T] & \quad \text{the set of integers from 1 to } T. \\
|U| & \quad \text{cardinality of } U. \\
\text{diam}(\Theta) = \max_{\theta_1, \theta_2} \|\theta_1 - \theta_2\| & \quad \text{diameter of } \Theta. \\
\text{diam}_A(\Theta) = \max_{a \in A} \max_{\theta_1, \theta_2} |a^T (\theta_1 - \theta_2)| & \quad \text{diameter of } \Theta \text{ under } A. \\
\mu(x) = (1 + \exp(-x))^{-1} & \quad \text{the logistic function at } x. \\
\ell(x, r) = -r \log \mu(x) - (1 - r) \log(1 - \mu(x)) & \quad \text{log-loss associated to } (x, r). \\
\ell_{t+1}(\theta) = \ell(a_t^T \theta, r_{t+1}) & \quad \text{instantaneous log-loss of } \theta \text{ at round } t. \\
\tilde{\ell}_{t+1}(\theta) = \ell(a_t^T \theta, 1 - r_{t+1}) & \quad \text{“reverse” instantaneous log-loss of } \theta \text{ at round } t. \\
H_t(\theta) = \sum_{s=1}^t \tilde{\mu}_s a_s a_s^T + \lambda_t I_d & \quad \text{Hessian of the cumulative-log loss at } \theta \text{ up to } t. \\
V_t = \sum_{s=1}^t a_s a_s^T / \kappa + \lambda_t I_d & \quad \text{linear-like design-matrix up to } t.
\end{align*}

Note that for all $\theta$ s.t $\|\theta\| \leq S$ we have $\tilde{\mu}(a_t^T \theta) \geq 1/\kappa$ by definition of $\kappa$. Therefore:

$$
\forall \theta \text{ s.t } \|\theta\| \leq S, \quad H_t(\theta) \succeq V_t. \quad (9)
$$

Below we define several “slowly growing” functions (uniformly denoted $\gamma_t(\delta)$ in the main paper). They will be used throughout the proofs.

\begin{align*}
\lambda_t(\delta) &= d \log((4 + t/4) / \delta), \\
\gamma_t(\delta) &= (S + 3/2)^2 \lambda_t(\delta), \\
\beta_t(\delta) &= (5/2 + (S + 3/2)^2 / S)^2 \gamma_t(\delta), \\
\nu_t(\delta) &= 1/2 + 2 \log \left( 2 \sqrt{t/4 + 1}/\delta \right), \\
\sigma_t(\delta) &= 8S^2 / 6 + 4 \log(t) + 9 \nu_t(\delta) + 18 \exp(1) \log(1 + t/(4d)), \\
\eta_t(\delta) &= 4 + 4 \log(t) + 16S^2 + (2 + 2S)^2 \nu_t(\delta)/2 + 8(1 + S) \log(1 + t/d).
\end{align*}

A.2 Useful Inequalities and Self-Concordant Control

A central idea when analyzing \textbf{LogB} is to tightly link \textit{estimation} errors \(e.g.\) between $\theta_1$ and $\theta_2$ to \textit{prediction} errors \(e.g.\) between $\tilde{\mu}(a_t^T \theta_1)$ and $\tilde{\mu}(a_t^T \theta_2)$. Exact Taylor expansion is a powerful tool to achieve this; as for previous works we will use it abundantly and in the following lines we introduce useful notations to this end. Specifically, for any $a \in \mathcal{A}$ and $x, y \in \mathbb{R}$ define:

\begin{align*}
\alpha(x, y) &= \int_0^1 \tilde{\mu}(x + v(y - x)) dv = \alpha(y, x), \\
\bar{\alpha}(x, y) &= \int_0^1 (1 - v) \tilde{\mu}(x + v(y - x)) dv.
\end{align*}

After exact Taylor expansions we have the following identities for all $\theta_1, \theta_2 \in \mathbb{R}^d$:

\begin{align*}
\mu(a_t^T \theta_2) - \mu(a_t^T \theta_1) &= \alpha(a_t^T \theta_1, a_t^T \theta_2) a_t^T (\theta_2 - \theta_1), \\
\ell_{t+1}(\theta_2) - \ell_{t+1}(\theta_1) &= \nabla \ell_{t+1}(\theta_1)^T (\theta_2 - \theta_1) + \bar{\alpha}(a_t^T \theta_1, a_t^T \theta_2) (a_t^T (\theta_2 - \theta_1))^2.
\end{align*}

Below are reminded some useful inequalities that stem from the self-concordance property of the logistic function (the fact that $|\ddot{\mu}| \leq \dot{\mu}$) The proofs can all be found in Appendix F of Abeille et al. (2021).

\begin{align*}
\alpha(x, y) &\geq (1 + |x - y|)^{-1} \tilde{\mu}(z) \text{ for } z \in \{x, y\}, \\
\bar{\alpha}(x, y) &\geq (2 + |x - y|)^{-1} \dot{\mu}(x), \\
\dot{\mu}(x) &\leq \tilde{\mu}(y) \exp(|x - y|).
\end{align*}
**Procedure 1 WarmUp (detailed)**

**input:** length $\tau$.

- Set $\lambda \leftarrow \lambda_\tau(\delta)$, initialize $V_0 \leftarrow \lambda I_d$.

**for** $t \in [1, \tau]$ **do**
- Play $a_t \in \arg \max_A \|a\|_{V_{t-1}^{-1}}$, observe $r_{t+1}$.
- Update $V_t \leftarrow V_{t-1} + a_t a_t^T / \kappa$.

**end for**

- Compute $\hat{\theta}_{\tau+1} \leftarrow \arg \min_\theta \sum_{s=1}^\tau \ell_s + \lambda \|\theta\|^2 / 2$.

**output:** $\Theta = \{ \theta, \|\theta - \hat{\theta}_{\tau+1}\|_{V_{\tau}} \leq \beta_\tau(\delta) \}$.

\[ \beta_\tau(\delta) \text{ is defined in Equation (12)} \]

**B WARM-UP PROCEDURE**

We recall the warm-up procedure in Procedure 1 for which we now we give the exact values for the “slowly growing” functions that we use.

**B.1 Warm-up Length and Parameter Set**

The goal of this section is to prove the claim behind Equation (4), tying the length of the warm-up phase to the diameter of the induced parameter set $\Theta$. The formal claim is made explicit in the following proposition.

**Proposition 5.** Let $\delta \in (0, 1]$. Setting $\tau = \mathcal{C}\kappa S^6 d^2 \log(T/\delta)^2$ ensures that $\Theta$ returned by $\text{WarmUp}(\tau)$ satisfies:

1. $\mathbb{P}(\theta_* \in \Theta) \geq 1 - \delta$,
2. $\text{diam}_A(\Theta) \leq 1$.

**Proof.** The set $\Theta$ returned by $\text{WarmUp}(\tau)$ is:

$$\Theta = \left\{ \theta, \|\theta - \hat{\theta}_{\tau+1}\|_{V_{\tau}} \leq \beta_\tau(\delta) \right\}.$$  \hfill (23)

where $\beta_\tau(\delta)$ is defined in Equation (12). It satisfies $\beta_\tau(\delta) \leq \mathcal{C} S^6 d \log(t/\delta)$.

To prove (1) we claim Lemma 1 which proof is deferred to Appendix C.1.

**Lemma 1.** Let $\delta \in (0, 1]$. Then:

$$\mathbb{P}\left(\forall t \geq 1, \|\theta_* - \hat{\theta}_{t+1}\|_{H_\tau(\theta_*)} \leq \beta_\tau(\delta) \right) \geq 1 - \delta.$$  \hfill (def. of $\Theta$)

The proof of (1) directly follows:

$$\mathbb{P}(\theta_* \in \Theta) = \mathbb{P}\left( \|\theta_* - \hat{\theta}_{\tau+1}\|_{V_{\tau}} \leq \beta_\tau(\delta) \right) \geq \mathbb{P}\left( \|\theta_* - \hat{\theta}_{\tau+1}\|_{H_\tau(\theta_*)} \leq \beta_\tau(\delta) \right) \geq 1 - \delta.$$  \hfill (Lemma 1)

To prove (2) we claim Lemma 2 which proof is provided in Appendix B.2:

**Lemma 2.** Let $T \in \mathbb{N}^+$ and $\tau \in [T]$. Let $\Theta$ the set returned by $\text{WarmUp}(\tau)$. Then:

$$\text{diam}_A(\Theta) \leq 4\sqrt{\frac{\kappa \beta_\tau(\delta) d \log(1 + T)}{\tau}}.$$  \hfill (def. of $\Theta$)

Therefore $\tau = 16\kappa d \beta_\tau(\delta) \log(1 + T)$ ensures that $\text{diam}_A(\Theta) \leq 1$. Since $\beta_\tau(\delta) \leq \mathcal{C} S^6 d \log(T/\delta)$ setting:

$$\tau = \mathcal{C}\kappa S^6 d^2 \log(T/\delta)^2,$$

yields $\text{diam}_A(\Theta) \leq 1$ which finishes proving (2).
B.2 Proof of Lemma 2

Lemma 2. Let \( T \in \mathbb{N}^+ \) and \( \tau \in [T] \). Let \( \Theta \) the set returned by \text{WarmUp}(\tau). Then:

\[
\text{diam}_\mathcal{A}(\Theta) \leq 4\sqrt{\frac{\kappa \beta_T(\delta) d \log(1 + T)}{\tau}}.
\]

Proof. The proof is inspired by the demonstration of Lemma 8 of from Valko et al. (2014). Recall:

\[
\Theta = \left\{ \theta, \|\theta - \hat{\theta}_{\tau+1}\|_{\mathbf{V}_\tau}^2 \leq \beta_\tau(\delta) \right\},
\]

with \( \mathbf{V}_\tau = \sum_{s=1}^\tau a_s a_s^T/\kappa + \lambda_\tau(\delta)\mathbf{I}_d \) and for all \( s \leq \tau \):

\[
a_s \in \arg \max_{\mathcal{A}} \|a\|_{\mathbf{V}_{s-1}^{-1}}.
\]

Therefore:

\[
\text{diam}_\mathcal{A}(\Theta) = \max_{\theta_1, \theta_2} \max_{a \in \mathcal{A}} |a^T(\theta_1 - \theta_2)|.
\]

\[
\leq \max_{\theta_1, \theta_2} \max_{a \in \mathcal{A}} \|a\|_{\mathbf{V}_{\tau-1}} \|\theta_1 - \theta_2\|_{\mathbf{V}_{\tau}}.
\]

(Cauchy-Schwarz)

\[
\leq 2\sqrt{\beta_\tau(\delta)} \max_{a \in \mathcal{A}} \|a\|_{\mathbf{V}_{\tau-1}} \quad (\theta_1, \theta_2 \in \Theta)
\]

\[
= 2\sqrt{\beta_\tau(\delta)} \sqrt{\max_{a \in \mathcal{A}} \|a\|_{\mathbf{V}_{\tau-1}}^2}
\]

\[
= 2\sqrt{\beta_\tau(\delta)} \tau^{-1/2} \sqrt{\sum_{s=1}^\tau \max_{a \in \mathcal{A}} \|a\|_{\mathbf{V}_{s-1}}^2}
\]

\[
\leq 2\sqrt{\beta_\tau(\delta)} \tau^{-1/2} \sum_{s=1}^\tau \max_{a \in \mathcal{A}} \|a\|_{\mathbf{V}_{s-1}}^2 \quad (\mathbf{V}_\tau \succeq \mathbf{V}_{s-1})
\]

\[
\leq 2\sqrt{\beta_\tau(\delta)} \tau^{-1/2} \sum_{s=1}^\tau \|a_s\|_{\mathbf{V}_{s-1}}^2 \quad (\text{Equation } (24))
\]

\[
= 2\sqrt{\beta_\tau(\delta)} \tau^{-1/2} \sqrt{\kappa} \sqrt{\sum_{s=1}^\tau \|a_s/\sqrt{\kappa}\|_{\mathbf{V}_{s-1}}^2}
\]

\[
\leq 4\sqrt{\beta_\tau(\delta)} \tau^{-1/2} \sqrt{\kappa} \sqrt{d} \log(1 + \tau/d) \quad (\text{Lemma } 9)
\]

which yields the announced result since \( T \geq \tau \). Notice the re-normalization of the action by \( \kappa \) so that we can apply the Elliptical Potential Lemma (Lemma 9) directly.

\[\square\]

B.3 ONS and Warm-Up

The ONS-like approaches of Zhang et al. (2016); Jun et al. (2017) do not use a warm-up procedure and rely on a “crude” parameter set \( \Theta_0 = \{\theta, \|\theta\| \leq S\} \). As discussed in the main paper (see Section 3.3) it is natural to wonder whether their mechanisms could be directly improved (by order of magnitude \( \kappa \)) by using the refined parameter \( \Theta \) returned by the warm-up procedure. This is unfortunately not the case; both approaches hard-code the \( \kappa \)-dependency in the size of their parameter updates. This dependency can only be marginally reduced when using \( \Theta \).

For instance Jun et al. (2017) rely the exp-concavity constant of the log-loss to design their update rule. Formally, for a parameter set \( \Theta' \) it is defined as (see Hazan (2016, Definition 4.1)):

\[
\rho(\Theta') := \sup_{r > 0} \{ r \text{ s.t. } \nabla^2_\theta \ell(a^T \theta, r) \succeq r \nabla_\theta \ell(a^T \theta, r) \nabla_\theta \ell(a^T \theta, r)^T, \forall \theta \in \Theta', \forall (a, r) \in \mathcal{A} \times \{0, 1\} \}.
\]
After some straight-forward manipulations it writes as:

$$\rho(\Theta') = \sup_{r > 0} \left\{ r \text{ s.t. } r \leq \frac{\hat{\mu}(a^T \theta)}{\mu(a^T \theta) - r}, \forall \theta \in \Theta', \forall (a, r) \in \mathcal{A} \times \{0, 1\} \right\}$$

$$\leq 2 \min_{\theta \in \Theta'} \min_{a \in \mathcal{A}} \hat{\mu}(a^T \theta).$$

The update rule designed by Jun et al. (2017) hard-codes a factor $\rho(\Theta_0)^{-1}$ in their update rule and therefore in the radius of the associated confidence regions. This induces exponentially inflated confidence sets as:

$$\rho(\Theta_0)^{-1} \geq \frac{\kappa}{2} = C \exp(S).$$

Refining this dependency by using a smaller $\Theta$ does not remove such exponential dependencies in problem-dependent constants (e.g. $\|\theta_*\|$, $S$). Indeed if $\Theta$ is the set returned by $\text{WarmUp}(\tau)$ under the conditions of Proposition 5:

$$\rho(\Theta)^{-1} \geq C \exp(\|\theta_*\|).$$

A similar argument holds for the update mechanism Zhang et al. (2016), which rely on the strong-convexity constant of the log-loss.
C CONCENTRATION AND CONFIDENCE SETS

C.1 Refinement of Faury et al. (2020)

In the following, we consider that we have adaptively collected the dataset \( \{a_t, r_{t+1}\}_t \). We denote:

\[
\hat{\theta}_{t+1} := \arg\min_{\theta} \sum_{s=1}^{t} \ell_{s+1}(\theta) + \lambda_t ||\theta||^2 / 2 ,
\]

where \( \lambda_t(\delta) \) is defined in Equation (10). Directly following the proof of Faury et al. (2020, Lemma 11):

\[
P\left( \forall t \geq 1, \left\| \theta_* - \hat{\theta}_{t+1} \right\|^2_{H_t(\theta_\star)} \leq 4(1 + 2S)^2 \gamma_t(\delta) \right) \geq 1 - \delta ,
\]

(25)

where \( \hat{\theta}_{t+1} \) is obtained by “projecting” \( \tilde{\theta}_{t+1} \) on the ball \( \{||\theta|| \leq S\} \) through a non-convex minimization routine. The slowly growing function \( \gamma_t(\delta) \) is obtained after applying simple upper-bounding operations to Faury et al. (2020, Theorem 1) and is formally defined in Equation (11). It checks:

\[
\gamma_t(\delta) \leq C S^2 d \log(t/\delta) .
\]

The following proposition establishes that Equation (25) still holds when \( \hat{\theta}_{t+1} \) is replaced by \( \tilde{\theta}_{t+1} \), at the price of only a minor degradation of the bound. This essentially removes the need to solve a non-convex program whenever \( ||\hat{\theta}_{t+1}|| \geq S \). The function \( \beta_t(\delta) \) is defined in Equation (12) and checks \( \beta_t(\delta) \leq C S^2 d \log(t/\delta) \).

**Lemma 1.** Let \( \delta \in (0, 1) \). Then:

\[
P\left( \forall t \geq 1, \left\| \theta_* - \tilde{\theta}_{t+1} \right\|^2_{H_t(\theta_\star)} \leq \beta_t(\delta) \right) \geq 1 - \delta .
\]

**Remark 1.** Whenever \( ||\hat{\theta}_{t+1}|| \leq S \) one can directly use the bound given in Equation (25), which is then valid for \( \hat{\theta}_{t+1} = \tilde{\theta}_{t+1} \).

**Proof.** The proof leverages the self-concordance property of the logistic function by using some intermediary results from Abeille et al. (2021). In the following, we denote for all \( \theta \):

\[
g_t(\theta) := \sum_{s=1}^{t} \mu(a_s^T \theta) a_s + \lambda \theta \quad \text{and} \quad G_t(\theta) = \sum_{s=1}^{t} \alpha(a_s^T \theta, a_s^T) a_s a_s^T ,
\]

where \( \alpha(x, y) \) is defined in Appendix A.1. Further, define the event \( E_\delta \) as follows:

\[
E_\delta := \left\{ \forall t \geq 1, \left\| g_t(\theta_\star) - g_t(\tilde{\theta}_{t+1}) \right\|^2_{H_t(\theta_\star)^{-1}} \leq \gamma_t(\delta) \right\} .
\]

By Lemma 1 of Faury et al. (2020) we have that \( P(E_\delta) \geq 1 - \delta \). From the demonstration of Lemma 2 from Abeille et al. (2021) it can also be extracted that if \( E_\delta \) holds then for any \( t \geq 1 \):

\[
H_t(\theta_\star) \leq (1 + \gamma_t(\delta)/\lambda_t(\delta) + \sqrt{\gamma_t(\delta)/\lambda_t(\delta)}) G_t(\tilde{\theta}_{t+1})
\]

\[
= (5/2 + (S + 3/2)^2 + S) G_t(\tilde{\theta}_{t+1}) .
\]

(26)

Finally, recall that by the mean-value theorem we have the following identity for any \( \theta \):

\[
g_t(\theta) - g_t(\theta_\star) = G_t(\theta)(\theta - \theta_\star) .
\]

(27)

We conclude by chaining inequalities, assuming that \( E_\delta \) holds (which happens with probability at least \( 1 - \delta \)):

\[
\left\| \theta_* - \tilde{\theta}_{t+1} \right\|^2_{H_t(\theta_\star)} \leq (5/2 + (S + 3/2)^2 + S) \left\| \theta_* - \hat{\theta}_{t+1} \right\|^2_{G_t(\tilde{\theta}_{t+1})}
\]

(26)

\[
= (5/2 + (S + 3/2)^2 + S) \left\| g_t(\theta_\star) - g_t(\tilde{\theta}_{t+1}) \right\|^2_{G_t(\tilde{\theta}_{t+1})^{-1}}
\]

(27)

\[
\leq (5/2 + (S + 3/2)^2 + S)^2 \left\| g_t(\theta_\star) - g_t(\tilde{\theta}_{t+1}) \right\|^2_{H_t(\theta_\star)^{-1}}
\]

(26)

\[
\leq (5/2 + (S + 3/2)^2 + S)^2 \gamma_t(\delta) = \beta_t(\delta) ,
\]

(26)

which proves the announced result.

\[\square\]
C.2 Statement of Theorem 3

The goal of this section is to justify the confidence sets used in the main paper through the statement of the more general Theorem 3 (see below). In particular, we deal here with the optimization errors introduced when running the ECOLog procedure.

Algorithm 4 Efficient Local Learning for Logistic Bandits (ECOLog, sequential form)

\textbf{input:} Compact convex sets \{Θt\}t, optimization accuracies \{εt\}t.

Let \( W_1 ← I_d, \theta'_1 ∈ Θ \).

\textbf{for} \( t ≥ 1 \) \textbf{do}

Receive the pair \((a_t, r_{t+1})\).

Define \( \theta_{t+1} \) as:

\[ \theta_{t+1} = \arg\min_{θ ∈ Θ_t} \left( \frac{1}{2 + D} \|θ - θ'_t\|^2_{W_t} + \ell_{t+1}(θ) \right) . \]

Compute \( θ'_{t+1} \) by solving the above program to accuracy \( ε_t \).

Update \( W_{t+1} ← W_t + \mu(a_t^Tθ'_{t+1})a_t^T \).

\textbf{end for}

We detail in Algorithm 4 the pseudo-code for ECOLog in its sequential form. It takes as input a sequence of compact convex sets \{Θt\}t and a sequence \{εt\}t of optimization accuracy. Note the use of:

\[ D := \sup_{t ≥ 1} \text{diam}_A(Θ_t) \]

If this quantity is unknown, \( D \) is replaced by an upper-bound on the supremum (the tighter, the better). Our use of ECOLog in both Algorithms 1 and 2 falls under this general description. For instance Algorithm 1 instantiates this procedure with \( Θ_t ≡ Θ \) (the set returned by the warm-up) for which \( D ≤ 1 \) (see Proposition 5).

We assume that at each round \( t ≥ 1 \) the true minimizer:

\[ \theta_{t+1} = \arg\min_{θ ∈ Θ_t} \left( \frac{1}{2 + D} \|θ - θ'_t\|^2_{W_t} + \ell_{t+1}(θ) \right) , \]

(28)

can computed up to accuracy \( ε_t \). In other words, we have access to \( θ'_{t+1} \) such that:

\[ \|θ_{t+1} - θ'_{t+1}\| ≤ ε_t . \]

(29)

We discuss in Appendix E.1 how such \( θ'_{t+1} \) can be efficiently computed. We denote \{(θ'_{t+1}, W_{t+1})\}t the sequence of parameters maintained by ECOLog((Θt), {εt}) and claim the following concentration bound. The function \( ν_t(δ) \) is defined in Equation (13). Numerical constants can be improved by a more careful analysis.

Theorem 3. Let \( δ ∈ (0, 1) \) and assume that \( θ_s ∈ Θ_t \) for all \( t ≥ 1 \). Then:

\[ \mathbb{P} \left( \forall t ≥ 1, \|θ'_{t+1} - θ_s\|^2_{W_{t+1}} ≤ 8S^2 + 4 \sum_{s=1}^{t} s \varepsilon_s^2 + 2D^2 + (2 + D)^2 ν_t(δ)/2 + 2(2 + D)^2 \exp(Dd) \log(1 + t/(4d)) \right) ≥ 1 - δ . \]

C.3 Proof of Theorem 3

An important technical piece of our analysis resides in the following Lemma, which derives a local quadratic lower-bound for the logistic loss \( ℓ_{t+1}(θ) \). It is extracted from the self-concordance analysis of Abeille et al. \((2021)\). A slightly stronger form, derived through other means, also appears in Jézéquel et al. \((2020)\). The proof is deferred to Appendix C.3.1.

Proposition 6 (Local Quadratic Lower-Bound). For all \( t ≥ 1 \) and any \( θ, θ_r ∈ Θ_t \):

\[ ℓ_{t+1}(θ) ≥ ℓ_{t+1}(θ_r) + \nabla ℓ_{t+1}(θ_r)^T(θ - θ_r) + \frac{\mu(a_t^Tθ_r)}{2 + \text{diam}_A(Θ_t)}(a_t^T(θ - θ_r))^2 . \]
Another important intermediary result is given by the following Lemma. It is obtained by directly leveraging the update rule. The proof is deferred to Appendix C.3.2.

**Lemma 3.** At any round $t \geq 1$:
\[
\nabla \ell_{t+1}(\theta_{t+1})^T (\theta_{t+1} - \theta_*) \leq (1 + D/2)^{-1} (\theta_{t+1} - \theta_1^*)^T \mathbf{W}_t (\theta_* - \theta_{t+1}) .
\]

Combining Proposition 6 and Lemma 3 yields the following result, tying the deviation between $\theta_{t+1}'$ and $\theta_*$ with the excess loss incurred by $\{\theta_{t+1}'\}_{s=1}^t$. The proof is deferred to Appendix C.3.3.

**Lemma 4.** For any $t \geq 1$ the following holds:
\[
\|\theta_{t+1}' - \theta_*\|_{\mathbf{W}_{t+1}}^2 \leq 4S^2 + 4 \sum_{s=1}^t s\varepsilon_s^2 + (4 + 2D) \left[ \sum_{s=1}^t \ell_{s+1}(\theta_*) - \ell_{s+1}(\theta_{s+1}) \right] .
\]

To obtain a valid confidence set from Lemma 4 we are left to bound $\sum_{s=1}^t \ell_{s+1}(\theta_*) - \ell_{s+1}(\theta_{s+1})$. To do so, and inspired by the analysis of Jézéquel et al. (2020) in the online convex optimization setting, we introduce:
\[
\bar{\theta}_t := \arg \min_{\theta} \left( \frac{1}{2 + D} \|\theta - \theta_*\|_{\mathbf{W}_t}^2 + \ell(a_t^T \theta, 0) + \ell(a_t^T \theta, 1) \right) .
\]

Note that $\bar{\theta}_t$ is $\mathcal{F}_t$-measurable ($\theta_{t+1}'$ is $\mathcal{F}_{t+1}$ measurable). We rely on the following decomposition and bound each term of the r.h.s separately:
\[
\sum_{s=1}^t \ell_{s+1}(\theta_*) - \ell_{s+1}(\theta_{s+1}) = \left[ \sum_{s=1}^t \ell_{s+1}(\theta_*) - \ell_{s+1}(\bar{\theta}_s) \right] + \left[ \sum_{s=1}^t \ell_{s+1}(\bar{\theta}_s) - \ell_{s+1}(\theta_{s+1}) \right] .
\]

The first term is bounded with high probability as stated below. The proof is deferred to Appendix C.3.4 and uses a 1-dimensional version of a concentration result from Faury et al. (2020).

**Lemma 5.** Let $\delta \in (0, 1]$. We have:
\[
\mathbb{P} \left( \forall t \geq 1, \sum_{s=1}^t \ell_{s+1}(\theta_*) - \ell_{s+1}(\bar{\theta}_s) \leq (2 + D) \nu_t(\delta)/4 + D^2(2 + D)^{-1} \right) \geq 1 - \delta' .
\]

We now turn on bounding the second term in Equation (31) - that is:
\[
\sum_{s=1}^t \ell_{s+1}(\bar{\theta}_s) - \ell_{s+1}(\theta_{s+1}) .
\]

We claim the following intermediary result, which proof is deferred to Appendix C.3.5.

**Lemma 6.** The following result holds for any $t \geq 1$:
\[
\sum_{s=1}^t \ell_{s+1}(\bar{\theta}_s) - \ell_{s+1}(\theta_{s+1}) \leq (1 + D) \sum_{s=1}^t \bar{\mu}(a_s^T \bar{\theta}_s) \|a_s\|_{\mathbf{W}_{s+1}}^2 .
\]

We finish the bound by the following result, a consequence of the self-concordance property of the logistic function. The proof is deferred to Appendix C.3.6.

**Lemma 7.** The following result holds for any $t \geq 1$:
\[
\sum_{s=1}^t \bar{\mu}(a_s^T \bar{\theta}_s) \|a_s\|_{\mathbf{W}_{s+1}}^2 \leq \exp(D)d \log ((1 + t/(4d)) .
\]
Combining Lemmas 6 and 7 yields that:

\[
\sum_{s=1}^{t} \ell_{s+1}(\tilde{\theta}_s) - \ell_{s+1}(\theta_{s+1}) \leq (1 + D) \exp(D) \log((1 + t/(4d))).
\]

Assembling this result with Equation (31) yields that \( \forall t \geq 1: \)

\[
\sum_{s=1}^{t} \ell_{s+1}(\theta_s) - \ell_{s+1}(\theta_{s+1}) \leq \left[ \sum_{s=1}^{t} \ell_{s+1}(\theta_s) - \ell_{s+1}(\tilde{\theta}_s) \right] + (1 + D) \exp(D) \log((1 + t/(4d))) .
\]

Thanks to Lemma 5 this further yields that with probability at least 1 \( - \delta: \)

\[
\forall t \geq 1, \sum_{s=1}^{t} \ell_{s+1}(\theta_s) - \ell_{s+1}(\theta_{s+1}) \leq (2 + D) \mu_t(\delta)/4 + D^2(2 + D)^{-1} + (1 + D) \exp(D) \log((1 + t/(4d))) .
\]

Assembling this result with Lemma 4 along with simple bounding operations yield the announced result.

C.3.1 Proof of Proposition 6

**Proposition 6** (Local Quadratic Lower-Bound). For all \( t \geq 1 \) and any \( \theta, \theta_r \in \Theta_t: \)

\[
\ell_{t+1}(\theta) \geq \ell_{t+1}(\theta_r) + \nabla \ell_{t+1}(\theta_r)^T (\theta - \theta_r) + \frac{\mu(a_t^T \theta_r)}{2 + \text{diam}_A(\Theta_t)} (a_t^T (\theta - \theta_r))^2.
\]

**Proof.** By a exact second-order Taylor of \( \ell_{t+1}(\theta) \) decomposition around \( \theta_r \) yields (see Equation (19)):

\[
\ell_{t+1}(\theta) = \ell_{t+1}(\theta_r) + \nabla \ell_{t+1}(\theta_r)^T (\theta - \theta_r) + \alpha(a_t^T \theta_r)(a_t^T (\theta - \theta_r))^2,
\]

Further by Equation (21) we have:

\[
\alpha(a_t^T \theta, a_t^T \theta_r) \geq \alpha(a_t^T \theta_r)/\left(2 + |a_t^T (\theta_r - \theta)|\right),
\]

\[
\geq \alpha(a_t^T \theta_r)/(2 + \text{diam}_A(\Theta_t)), \quad (\theta_r, \theta \in \Theta_t, \text{def. of diam}_A(\Theta_t))
\]

which concludes the proof. \( \square \)

C.3.2 Proof of Lemma 3

**Lemma 3.** At any round \( t \geq 1: \)

\[
\nabla \ell_{t+1}(\theta_{t+1})^T (\theta_{t+1} - \theta_s) \leq (1 + D/2)^{-1}(\theta_{t+1} - \theta'_t)^T W_t(\theta_s - \theta_{t+1}) .
\]

**Proof.** Denote \( \tilde{L}_{t+1}(\theta) := (2 + D)^{-1}\|\theta - \theta'_t\|^2_{W_t} + \ell_{t+1}(\theta) \) the function minimized by \( \theta_{t+1} \) over \( \Theta_t \). Since \( \Theta_t \) is a convex set and \( \tilde{L}_{t+1} \) a convex function, we have that for any \( \theta \in \Theta_t \) (see Lemma 11):

\[
0 \leq \nabla \tilde{L}_{t+1}(\theta_{t+1})^T (\theta - \theta_{t+1})
\]

\[
= (1 + D/2)^{-1}W_t(\theta_{t+1} - \theta'_t)^T (\theta - \theta_{t+1})
\]

\[
= (1 + D/2)^{-1}(\theta_{t+1} - \theta'_t)^T W_t(\theta - \theta_{t+1}) + \nabla \ell_{t+1}(\theta_{t+1})^T (\theta - \theta_{t+1})
\]

Taking \( \theta = \theta_s \in \Theta_t \) (by assumption) in the above inequality yields the announced result. \( \square \)

C.3.3 Proof of Lemma 4

**Lemma 4.** For any \( t \geq 1 \) the following holds:

\[
\|\theta'_{t+1} - \theta_s\|^2_{W_{t+1}} \leq 4S^2 + 4 \sum_{s=1}^{t} \|s\|^2 + (4 + 2D) \left[ \sum_{s=1}^{t} \ell_{s+1}(\theta_s) - \ell_{s+1}(\theta_{s+1}) \right] .
\]
Proof. By Proposition 6, and because \( \theta_{t+1}, \theta_s \in \Theta_t \) (by construction for \( \theta_{t+1} \) and by assumption for \( \theta_s \)) the following holds for any \( s \geq 1 \):

\[
\ell_{s+1}(\theta_s) \geq \ell_{s+1}(\theta_{s+1}) + \nabla \ell_{s+1}(\theta_{s+1})^T(\theta_s - \theta_{s+1}) + \frac{\mu(a_s^T \theta_{s+1})}{2 + \text{diam}_A(\Theta_t)} (a_s^T(\theta_s - \theta_{s+1}))^2
\]

\[
\geq \ell_{s+1}(\theta_{s+1}) + \nabla \ell_{s+1}(\theta_{s+1})^T(\theta_s - \theta_{s+1}) + \frac{\mu(a_s^T \theta_{s+1})}{2 + D} (a_s^T(\theta_s - \theta_{s+1}))^2. \tag{D \geq \text{diam}_A(\Theta)}
\]

After re-arranging this yields:

\[
\ell_{s+1}(\theta_{s+1}) - \ell_{s+1}(\theta_s) \leq \nabla \ell_{s+1}(\theta_{s+1})^T(\theta_{s+1} - \theta_s) - (2 + D)^{-1} \mu(a_s^T \theta_{s+1})(a_s^T(\theta_{s+1} - \theta_s))^2.
\]

Using Lemma 3 in the above inequality gives:

\[
(1 + D/2) (\ell_{s+1}(\theta_{s+1}) - \ell_{s+1}(\theta_s)) \leq (\theta_{s+1} - \theta_s)^T W_s (\theta_{s+1} - \theta_s) - \frac{1}{2} \mu(a_s^T \theta_{s+1})(a_s^T(\theta_{s+1} - \theta_s))^2,
\]

\[
= -\frac{1}{2} ||\theta_{s+1} - \theta_s||^2_{W_s} + \frac{1}{2} ||\theta_s - \theta_s||^2_{W_s} - \frac{1}{2} ||\theta_{s+1} - \theta_s||^2_{W_s} - \frac{1}{2} ||\theta_{s+1} - \theta_s||^2_{W_s},
\]

\[
= -\frac{1}{2} ||\theta_{s+1} - \theta_s||^2_{W_{s+1}} + \frac{1}{2} ||\theta_s - \theta_s||^2_{W_s} - \frac{1}{2} ||\theta_{s+1} - \theta_s||^2_{W_s}.
\]

\[
\leq -\frac{1}{2} ||\theta_{s+1} - \theta_s||^2_{W_{s+1}} + \frac{1}{2} ||\theta_s - \theta_s||^2_{W_s} + \frac{1}{2} ||\theta_s - \theta_s||^2_{W_s}.
\]

\[
\leq -\frac{1}{2} ||\theta_{s+1} - \theta_s||^2_{W_{s+1}} + \frac{1}{2} ||\theta_s - \theta_s||^2_{W_s} + s\varepsilon_{s-1}^2.
\]

since \( ||\theta_s - \theta_s||^2_{W_s} \leq \lambda_{\text{max}}(W_s) ||\theta_s - \theta_s||^2 \leq 2s\varepsilon_{s-1}^2 \). By re-arranging:

\[
(2 + D) (\ell_{s+1}(\theta_s) - \ell_{s+1}(\theta_{s+1})) - ||\theta_{s+1} - \theta_s||^2_{W_{s+1}} - ||\theta_s - \theta_s||^2_{W_s} - 2s\varepsilon_{s-1}^2
\]

and summing from \( s = 1 \) to \( t \):

\[
(2 + D) \sum_{s=1}^t \ell_{s+1}(\theta_s) - \ell_{s+1}(\theta_{s+1}) \geq \sum_{s=1}^t \left[ ||\theta_{s+1} - \theta_s||^2_{W_{s+1}} - ||\theta_s - \theta_s||^2_{W_s} \right] - 2 \sum_{s=1}^t s\varepsilon_{s-1}^2
\]

\[
= ||\theta_{t+1} - \theta_s||^2_{W_{t+1}} - ||\theta_1 - \theta_s||^2_{W_1} - 2 \sum_{s=1}^t s\varepsilon_{s-1}^2 \quad \text{(telescopic sum)}
\]

\[
= ||\theta_{t+1} - \theta_s||^2_{W_{t+1}} - ||\theta_1 - \theta_s||^2 - 2 \sum_{s=1}^t s\varepsilon_{s-1}^2 \quad (W_1 = I_d)
\]

After re-arranging and setting \( \varepsilon_0 = 0 \) (there is no program to solve at \( t = 0 \)):

\[
||\theta_{t+1} - \theta_s||^2_{W_{t+1}} \leq 4S^2 + 2t \sum_{s=1}^t s\varepsilon_{s-1}^2 + (2 + D) \left[ \sum_{s=1}^t \ell_{s+1}(\theta_s) - \ell_{s+1}(\theta_{s+1}) \right].
\]

This concludes the proof as:

\[
||\theta_{t+1} - \theta_s||^2_{W_{t+1}} \leq 2 ||\theta_{t+1} - \theta_s||^2_{W_{t+1}} + 2 ||\theta_{t+1} - \theta_{t+1}||^2_{W_{t+1}} \quad ((a + b)^2 \leq 2(a^2 + b^2))
\]

\[
\leq 2 ||\theta_{t+1} - \theta_s||^2_{W_{t+1}} + 2(1 + t) ||\theta_{t+1} - \theta_{t+1}||^2 \quad (W_{t+1} \leq (1 + t)I_d)
\]

\[
\leq 2 ||\theta_{t+1} - \theta_s||^2_{W_{t+1}} + 4t\varepsilon_{t}^2.
\]

\[ \square \]
Lemma 5. Let $\delta \in (0, 1]$. We have:
\[
P \left( \forall t \geq 1, \sum_{s=1}^{t} \ell_{s+1}(\theta_s) - \ell_{s+1}(\bar{\theta}_s) \leq (2 + D)\nu_t(\delta) + 4D^2(2 + D)^{-1} \right) \geq 1 - \delta'.
\]

Proof. Using Proposition 6 with $\theta = \theta_*$ and $\theta_r = \bar{\theta}_s$ yields:
\[
\sum_{s=1}^{t} \ell_{s+1}(\theta_s) - \ell_{s+1}(\bar{\theta}_s) = \sum_{s=1}^{t} \nabla \ell_{s+1}(\theta_s)^T(\theta_s - \bar{\theta}_s) - (2 + D)^{-1} \sum_{s=1}^{t} \mu(a_s^T\theta_s)(a_s^T(\theta_s - \bar{\theta}_s))^2
\]
\[
= D \sum_{s=1}^{t} \eta_{s+1}x_s - D(2 + D)^{-1}X_t,
\]
where we denoted $x_s := a_s^T(\theta_s - \bar{\theta}_s)/D$, $X_t := \sum_{s=1}^{t} \mu(a_s^T\theta_s)x_s^2$ and $\eta_{s+1} := \mu(a_s^T\theta_s) - r_{s+1}$. We use a 1-dimensional version of the concentration result provided by Theorem 1 of Faury et al. (2020) to bound $\sum_{s=1}^{t} \eta_{s+1}x_s$. We remind its general form below for the sake of completeness.

**Theorem 4** (Theorem 1 of Faury et al. (2020)). Let $\{F_t\}_{t=1}^{\infty}$ be a filtration. Let $\{x_t\}_{t=1}^{\infty}$ be a stochastic process in $\mathbb{R}_2(d)$ such that $x_t$ is $F_t$-measurable. Let $\{\eta_t\}_{t=2}^{\infty}$ be a martingale difference sequence such that $\eta_{t+1}$ is $F_{t+1}$ measurable. Furthermore, assume that conditionally on $F_t$ we have $|\eta_{t+1}| \leq 1$ almost surely, and note $\sigma_t^2 := \mathbb{E}[\eta_{t+1}^2|F_t]$. Let $\lambda > 0$ and for any $t \geq 1$ define:
\[
H_t := \sum_{s=1}^{t} \sigma_s^2x_s^2 + \lambda I_d, \quad S_{t+1} := \sum_{s=1}^{t} \eta_{s+1}x_s.
\]
Then for any $\delta \in (0, 1]$:
\[
P \left( \exists t \geq 1, \|S_{t+1}\|_{H_t^{-1}} \geq \frac{\sqrt{\lambda}}{2} + \frac{2}{\sqrt{\lambda}} \log \left( \frac{\det (H_t)^{1/2}\lambda^{-1/2}}{\delta} \right) + \frac{2}{\sqrt{\lambda}} d \log(2) \right) \leq \delta.
\]

Recall that we use the filtration $F_t := \sigma(a_1, r_2, \ldots, a_t)$. In our case, $x_s$ is 1-dimensional, is $F_s$-measurable and satisfies $|x_s| \leq 1$ almost surely (by definition of $D$, and since both $\theta_*, \bar{\theta}_s \in \Theta_t$). Further, $\eta_{s+1}$ is $F_{s+1}$-measurable and thanks to Equation (1) we have:
\[
\mathbb{E}[\eta_{s+1}|F_s] = 0 \quad \text{and} \quad \mathbb{E}[\eta_{s+1}^2|F_s] = \mu(a_s^T\theta_s).
\]
Furthermore, note that with the notations of Theorem 4 we have $H_t = X_t + 1$. By a direct application of Theorem 4 we obtain that with probability at least $1 - \delta$:
\[
\forall t \geq 1, \sum_{s=1}^{t} \eta_{s+1}x_s \leq \sqrt{X_t + 1} \left( \frac{2\sqrt{X_t + 1}}{\delta} \right)
\]
\[
= \sqrt{X_t + \lambda} \left( \frac{2\sqrt{ \sum_{s=1}^{t} \mu(a_s^T\theta_s)z_s^2 + 1 } }{\delta} \right)
\]
\[
\leq \sqrt{X_t + 1} \left( \frac{2\sqrt{1/4 + 1}}{\delta} \right) \quad (\mu \leq 1/4, |z_s| \leq 1)
\]
\[
= \sqrt{\nu_t(\delta)} \sqrt{X_t + 1} \quad (\text{def. of } \nu_t(\delta))
\]
\[
\leq \frac{\nu_t(\delta)}{4D(2 + D)^{-1}} + D(2 + D)^{-1}(X_t + 1)
\]
where in the second to last inequality we used the fact that \(\forall a, b, \zeta > 0\) we have \(\sqrt{ab} \leq a/(2\zeta) + \zeta b/2\) (applied with \(a = \gamma_1(\delta), b = X_t + \lambda\) and \(\zeta = 2D(2+D)^{-1}\). Re-injecting in Equation (32) yields that with probability at least \(1 - \delta\):

\[
\forall t \geq 1, \quad \sum_{s=1}^{t} \ell_{s+1}(\theta_s) - \ell_{s+1}(\bar{\theta}_s) \leq (2 + D)\nu_t(\delta)/4 + D^2(2 + D)^{-1}.
\]

\[\blacksquare\]

C.3.5 Proof of Lemma 6

Lemma 6. The following result holds for any \(t \geq 1\):

\[
\sum_{s=1}^{t} \ell_{s+1}(\bar{\theta}_s) - \ell_{s+1}(\theta_{s+1}) \leq (1 + D) \sum_{s=1}^{t} \mu(a_s^T \bar{\theta}_s) \|a_s\|^2_{W_{s+1}^{-1}}.
\]

Proof. By convexity of \(\ell_{s+1}(.\cdot)\) one has that for all \(s \geq 1\):

\[
\ell_{s+1}(\bar{\theta}_s) - \ell_{s+1}(\theta_{s+1}) \leq \nabla \ell_{s+1}(\bar{\theta}_s)^T (\bar{\theta}_s - \theta_{s+1}) \\
\leq \|\nabla \ell_{s+1}(\bar{\theta}_s)\|_{W_{s+1}^{-1}} \|\bar{\theta}_s - \theta_{s+1}\|_{W_{s+1}} \quad \text{(Cauchy-Schwarz)} \tag{33}
\]

Since \(\ell(a_s^T \theta, 0) + \ell(a_s^T \theta, 1) = \ell_{s+1}(\theta) + \bar{\ell}_s(\theta)\), one can re-write the computation of \(\bar{\theta}_s\) as:

\[
\bar{\theta}_s = \arg\min_{\theta \in \Theta_s} \frac{1}{2 + D} \|\theta - \theta_s\|^2_{W_s} + (\ell_{s+1}(\theta) + \bar{\ell}_s(\theta)).
\]

By convexity of the objective function minimized by \(\bar{\theta}_s\) and convexity of \(\Theta_s\) we therefore have the following inequality (see Lemma 11) for any \(s \geq 1\):

\[
(1 + D/2)^{-1}(\bar{\theta}_s - \theta_s)^T W_s(\theta_{s+1} - \bar{\theta}_s) + \nabla \ell_{s+1}(\bar{\theta}_s)^T (\theta_{s+1} - \bar{\theta}_s) + \nabla \bar{\ell}_{s+1}(\bar{\theta}_s)^T (\theta_{s+1} - \bar{\theta}_s) \geq 0.
\]

since \(\theta_{s+1} \in \Theta_s\) by definition. By re-arranging this yields:

\[
(1 + D/2)\nabla \ell_{s+1}(\bar{\theta}_s)^T (\theta_{s+1} - \bar{\theta}_s) \geq (\bar{\theta}_s - \theta_s)^T W_s(\theta_{s+1} - \theta_{s+1}) + (1 + D/2)\nabla \ell_{s+1}(\bar{\theta}_s)^T (\theta_{s+1} - \bar{\theta}_s)
\]

\[
= \|\bar{\theta}_s - \theta_{s+1}\|^2_{W_s} + (\bar{\theta}_s - \theta_{s+1})^T W_s(\theta_{s+1} - \theta_{s+1}) + (1 + D/2)\nabla \ell_{s+1}(\bar{\theta}_s)^T (\theta_{s+1} - \bar{\theta}_s).
\]

By the same argument, since \(\bar{\theta}_s \in \Theta_s\) we also have the inequality:

\[
(\theta_{s+1} - \theta_s)^T W_s(\theta_{s+1} - \theta_s) \geq (1 + D/2)\nabla \ell_{s+1}(\theta_{s+1})^T (\theta_{s+1} - \bar{\theta}_s).
\]

Re-injecting above this yields that:

\[
(1 + D/2)\nabla \bar{\ell}_{s+1}(\bar{\theta}_s)^T (\theta_{s+1} - \bar{\theta}_s) \geq \|\bar{\theta}_s - \theta_{s+1}\|^2_{W_s} + (1 + D/2)(\bar{\theta}_s - \theta_{s+1})^T (\nabla \ell_{s+1}(\bar{\theta}_s) - \nabla \ell_{s+1}(\theta_{s+1}))
\]

\[
= \|\bar{\theta}_s - \theta_{s+1}\|^2_{W_s} + (1 + D/2)\mu(a_s^T \bar{\theta}_s - \mu(a_s^T \theta_{s+1}))a_s^T (\bar{\theta}_s - \theta_{s+1})
\]

\[
= \|\bar{\theta}_s - \theta_{s+1}\|^2_{W_s} + (1 + D/2)\alpha(a_s^T \bar{\theta}_s, a_s^T \theta_{s+1})(a_s^T (\bar{\theta}_s - \theta_{s+1}))^2
\]

\[
\geq \|\bar{\theta}_s - \theta_{s+1}\|^2_{W_s} + (1 + D/2)(1 + D)^{-1}\mu(a_s^T \theta_{s+1})(a_s^T (\bar{\theta}_s - \theta_{s+1}))^2
\]

where in the second to last inequality we used Equation (20) to obtain \(\alpha(a_s^T \bar{\theta}_s, a_s^T \theta_{s+1}) \geq (1 + D)^{-1}\mu(a_s^T \theta_{s+1})\) (since \(\theta_{s+1}, \bar{\theta}_s \in \Theta_s\)). After easy manipulations this yields:

\[
\|\bar{\theta}_s - \theta_{s+1}\|^2_{W_{s+1}} \leq (1 + D)\nabla \bar{\ell}_{s+1}(\bar{\theta}_s)^T (\theta_{s+1} - \bar{\theta}_s)
\]

\[
\leq (1 + D) \|\nabla \bar{\ell}_{s+1}(\bar{\theta}_s)\|_{W_{s+1}^{-1}} \|\bar{\theta}_s - \theta_{s+1}\|_{W_{s+1}}
\]
and therefore we obtain that \( \| \tilde{\theta}_s - \theta_{s+1} \|_{\mathbf{V}_{s+1}} \leq (1 + D) \| \nabla \ell_{s+1}(\tilde{\theta}_s) \|_{\mathbf{W}_{s+1}^{-1}} \). Assembling with Equation (33):

\[
\ell_{s+1}(\tilde{\theta}_s) - \ell_{s+1}(\theta_{s+1}) \leq (1 + D) \| \nabla \ell_{s+1}(\tilde{\theta}_s) \|_{\mathbf{W}_{s+1}^{-1}} \| \nabla \ell_{s+1}(\tilde{\theta}_s) \|_{\mathbf{W}_{s+1}^{-1}}
\]

\[
= (1 + D) \| \mu(a^T_s \tilde{\theta}_s) - r_{s+1} \| \mu(a^T_s \tilde{\theta}_s) - 1 + r_{s+1} \| a_s \|_{\mathbf{W}_{s+1}}^2
\]

\[
= (1 + D) \| \mu(a^T_s \tilde{\theta}_s) \| \mu(a^T_s \tilde{\theta}_s) - 1 \| a_s \|_{\mathbf{W}_{s+1}}^2 \quad (r_{s+1} \in \{0, 1\})
\]

\[
= (1 + D) \mu(a^T_s \tilde{\theta}_s) \| a_s \|_{\mathbf{W}_{s+1}}^2 \quad (\mu(1 - \mu) = \mu)
\]

Summing yields the announced result. \(\square\)

### C.3.6 Proof of Lemma 7

**Lemma 7.** The following result holds for any \( t \geq 1 \):

\[
\sum_{s=1}^{t} \mu(a^T_s \tilde{\theta}_s) \| a_s \|_{\mathbf{W}_{s+1}}^2 \leq \exp(D) d \log ((1 + t)/(4 d)) .
\]

**Proof.** By Equation (22), for all \( s \geq 1 \):

\[
\mu(a^T_s \tilde{\theta}_s) \leq \exp(\|a^T_s (\theta'_{s+1} - \tilde{\theta}_s)\|) \mu(a^T_s \theta_{s+1})
\]

\[
\leq \exp(D) \mu(a^T_s \theta'_{s+1}) . \quad (\theta_{s+1}, \tilde{\theta}_s \in \Theta_s, D \geq \text{diam}_A(\Theta_s))
\]

Denoting \( x_s = \sqrt{\mu(a^T_s \theta'_{s+1})} a_s \) and \( \mathbf{M}_{s+1} = \sum_{s=1}^{t} x_s x_s^T \), we have:

\[
\sum_{s=1}^{t} \mu(a^T_s \tilde{\theta}_s) \| a_s \|_{\mathbf{W}_{s+1}}^2 \leq \exp(D) \sum_{s=1}^{t} \mu(a^T_s \theta'_{s+1}) \| a_s \|_{\mathbf{W}_{s+1}}^2
\]

\[
\leq \exp(D) \sum_{s=1}^{t} \| x_s \|_{\mathbf{M}_{s+1}^{-1}}^2
\]

\[
= \exp(D) \sum_{s=1}^{t} \text{Tr}(\mathbf{M}_{s+1}^{-1} x_s x_s^T)
\]

\[
= \exp(D) \sum_{s=1}^{t} \text{Tr}(\mathbf{M}_{s+1}^{-1} (\mathbf{M}_{s+1} - \mathbf{M}_s))
\]

\[
\leq \exp(D) \log (|\mathbf{M}_{t+1}|/|\mathbf{M}_1|) \quad \text{(Lemma 4.6 of Hazan (2016))}
\]

\[
\leq \exp(D) d \log (1 + t/(4 d)) ,
\]

where we last used Lemma 10 along with \( \| x_s \|^2 \leq \mu(a^T_s \theta'_{s+1}) \leq 1/4 \). \(\square\)

### C.4 Proof of Proposition 3

We prove below Proposition 3 from the main paper. It justifies the confidence sets used in OFU-ECOLog.

In this context, we have \( \Theta_t \equiv \Theta \), the set returned by the warm-up procedure run with the conditions of Proposition 5 and \( \varepsilon_s = 1/s \).

**Proposition 3 (Confidence Set).** Let \( \delta \in (0, 1] \) and \( \{(\theta_t, \mathbf{W}_t)\} \), the parameters maintained by Algorithm 1 with \( \tau \) set according to Proposition 5. Then:

\[
P \left( \forall t \geq 1, \| \theta_t - \theta'_{t+1} \|_{\mathbf{W}_{t+1}}^2 \leq \sigma_t(\delta) \text{ and } \theta_t \in \Theta \right) \geq 1 - 2\delta .
\]

The function \( \sigma_t(\delta) \) is defined in Equation (14) and checks \( \sigma_t(\delta) \leq C S^2 d \log(t/\delta) \).
Proof. By Proposition 5 we know that $\text{diam}_{\mathcal{A}}(\Theta) \leq 1$ so we can set $D = 1$. For the rest of the proof we assume that the event $\{\theta_* \in \Theta\}$ holds - this happens with probability at least $1 - \delta$ according to Proposition 5. Theorem 3 therefore applies since $\Theta$ is convex and compact. This yields:

$$\mathbb{P}\left( \forall t \geq 1, \|\theta_* - \theta_{t+1}\|_{W_t}^2 \leq 8S^2 + 4 \sum_{s=1}^{t} s\varepsilon_s^2 + 2 + 9\nu_t(\delta) + 18 \exp(1) d \log(1 + t/(4d)) \right) \geq 1 - \delta .$$

After a classic bound on the harmonic function; for $t \geq 1$:

$$\sum_{s=1}^{t} s\varepsilon_s^2 = \sum_{s=1}^{t} 1/s \leq 1 + \log(t) ,$$

we are left to apply a naive union bound with the event $\{\theta_* \in \Theta\}$ to finish the proof.

C.5 A Data-Dependent Version

The following result justifies the confidence regions used in ada-OFU-ECOLog.

Proposition 7. Let $\delta \in (0, 1]$ and $\{(\theta_t, W_t, \Theta_t)\}_t$ maintained by Algorithm 2. Then:

$$\mathbb{P}\left( \forall t \geq 1, \theta_* \in \Theta_t \text{ and } \|\theta_* - \hat{\theta}_{t+1}\|_{W_{t+1}}^2 \leq \eta_t(\delta) \right) \geq 1 - 2\delta .$$

The function $\eta_t(\delta)$ is defined in Equation (15) and checks $\eta_t(\delta) \leq C S^2 d \log(t/\delta)$.

Proof. This result can be easily be retrieved from the proof of Theorem 3. The sets:

$$\Theta_{t+1} = \left\{ \theta, \|\theta - \hat{\theta}_{t+1}\|_{V_{t+1}}^2 \leq \beta_t(\delta) \right\} ,$$

maintained in Algorithm 2 are indeed compact and convex. Further, they contain $\theta_*$ with high probability:

$$1 - \delta \leq \mathbb{P}\left( \forall t \geq 1, \|\theta_* - \hat{\theta}_{t+1}\|_{V_t}^2 \leq \beta_t(\delta) \right) \quad \text{(Lemma 1)}$$

$$\leq \mathbb{P}\left( \forall t \geq 1, \|\theta_* - \hat{\theta}_{t+1}\|_{V_t}^2 \leq \beta_t(\delta) \right) \quad \text{(Equation (9))}$$

$$= \mathbb{P}\left( \forall t \geq 1, \theta_* \in \Theta_t \right) .$$

Further, recall that the inequality:

$$\dot{\mu}(a_s^T \hat{\theta}_s) \leq 2\dot{\mu}(a_s^T \theta_{s+1}) ,$$

holds by construction in Algorithm 2. When it is not satisfied, the couple $(a_s, r_{s+1})$ is not fed to the ECOLog procedure. This essentially allows to replace $\exp(D)$ in Lemma 7 by a constant factor (here, 2). From there, following the demonstration of Theorem 3 up to straight-forward adaptations (e.g to deal with the fact that some rounds are ignored from the learning when the above inequality is not satisfied) yields that under the event $\{\forall t \geq 1, \theta_* \in \Theta_t\}$:

$$\mathbb{P}\left( \forall t \geq 1, \|\theta_* - \theta_{t+1}\|_{W_{t+1}}^2 \leq \eta_t(\delta) \right) \geq 1 - \delta .$$

A union bound finishes the proof.
D REGRET BOUNDS

To reduce clutter and fit with the notations adopted in the main text, we go back in this section to identifying \( \theta_t \) and its \( \varepsilon \)-approximation \( \theta'_t \). This does not impact the validity of the regret bounds - the effects of optimization errors are fully dealt with in the radius of the confidence sets we designed in Appendix C.2.

D.1 Proof of Theorem 1

**Theorem 1** (Regret Bound). Let \( \delta \in (0, 1] \). Setting \( \tau = \kappa \zeta S^6 d^2 \log(T/\delta)^2 \) ensures the regret of \( \text{OFU-ECOLog}(\delta, \tau) \) satisfies with probability at least \( 1 - 2\delta \):

\[
\text{Regret}(T) \leq \kappa S \delta \log(T/\delta) \sqrt{T \mu(a_t^T \theta_t)} + \kappa S^6 \delta d^2 \log(T/\delta)^2.
\]

**Algorithm 1** \( \text{OFU-ECOLog} \)

**input:** failure level \( \delta \), warm-up length \( \tau \).

Set \( \Theta \leftarrow \text{WarmUp}(\tau) \) (see Procedure 1).

Initialize \( \theta_{t+1} \in \Theta, W_{t+1} \leftarrow I_d \) and \( C_{t+1}(t) \leftarrow \Theta \).

for \( t \geq \tau + 1 \) do

Play \( a_t \in \arg \max_{a \in A} a^T \theta \).

Observe reward \( r_{t+1} \), construct loss \( \ell_{t+1}(\theta) = \ell(a_t^T \theta, r_{t+1}) \).

Compute \( (\theta_{t+1}, W_{t+1}) \leftarrow \text{ECOLog}(1/t, \Theta, \ell_{t+1}, W_t, \theta_t) \) (see Procedure 2).

Compute \( C_{t+1}(t) \leftarrow \{ \| \theta - \theta_{t+1} \|^2_{W_{t+1}} \leq \sigma_t(\delta) \} \).

end for

**Proof.** According to Proposition 3 (its detailed version in Appendix C.4) setting \( \tau = \kappa \zeta S^6 d^2 \log(T/\delta)^2 \) ensures:

\[
P \left( \theta_* \in \Theta \text{ and } \| \theta_t - \theta_* \|^2_{W_t} \leq \sigma_t(\delta) \text{ for all } t \geq \tau + 1 \right) \geq 1 - 2\delta,
\]

In the rest of the proof we assume that the above event, denoted \( E_\delta \), holds.

Since \( \mu(\cdot) \in (0, 1) \) the regret incurred during warm-up can be directly bounded by \( \tau \). Therefore for \( T \geq \tau + 1 \):

\[
\text{Regret}(T) \leq \kappa \zeta S^6 d^2 \log(T/\delta) + \sum_{t=\tau+1}^{T} \mu(a_t^T \theta_t) - \mu(a_t^T \theta_*)
\]

\[
\leq \kappa \zeta S^6 d^2 \log(T/\delta) + R(T),
\]

where we defined \( R(T) = \sum_{t=\tau+1}^{T} \mu(a_t^T \theta_t) - \mu(a_t^T \theta_*) \). To control this term we follow the usual strategy for bounding the regret of optimistic algorithms, and re-use tools introduced by Faury et al. (2020); Abeille et al. (2021) - adapted to our confidence set. In the following, we denote for \( t \geq \tau + 1 \):

\[
(a_t, \hat{\theta}_t) \in \arg \max_{A, C_t(\delta)} a^T \theta.
\]

where \( C_t(\delta) = \{ \theta, \| \theta_t - \theta_* \|^2_{W_t} \leq \sigma_t(\delta) \} \). Because \( E_\delta \) holds this implies that the couple \( (a_t, \hat{\theta}_t) \) is optimistic. Formally: \( a_t^T \hat{\theta}_t \geq a_t^T \theta_* \). We start by tying the regret to the prediction error of \( \hat{\theta}_{t+1} \) and continue with a second-order Taylor expansion.

\[
R(T) = \sum_{t=\tau+1}^{T} \mu(a_t^T \theta_t) - \mu(a_t^T \theta_*)
\]

\[
\leq \sum_{t=\tau+1}^{T} \mu(a_t^T \hat{\theta}_t) - \mu(a_t^T \theta_*) \quad \text{(optimism, } \mu \not\nearrow)\]

\[
\leq \sum_{t=\tau+1}^{T} \hat{\mu}(a_t^T \theta_*) a_t^T (\hat{\theta}_t - \theta_*) + \hat{\mu}(a_t^T \theta_*) a_t^T (\hat{\theta}_t - \theta_*)^2 \quad \text{(Taylor, } |\hat{\mu}| \leq \hat{\mu})
\]

\[
=: R_1(T) + R_2(T).
\]
We last applied Lemma 9 with \( x_t = a_t / \sqrt{\kappa} \), and proceeded with some simple upper-bounding operations. The second to last inequality is a consequence of Abeille et al. (2021, Lemma 9) which ensures:

\[
\begin{align*}
\hat{\mu}(a_t^T \theta_{s+1}) &\geq \hat{\mu}(a_t^T \theta_s) \exp(-|a_t^T (\theta_{s+1} - \theta_s)|) \\
&\geq \hat{\mu}(a_t^T \theta_s) \exp(-1) \\
&\geq \exp(-1)\kappa.
\end{align*}
\]

We now turn our attention to \( R_1(T) \).

\[
R_1(T) = \sum_{t = \tau+1}^{T} \hat{\mu}(a_t^T \theta_s) a_t^T (\bar{\theta}_t - \theta_s)
\leq \sum_{t = \tau+1}^{T} \sqrt{\hat{\mu}(a_t^T \theta_s) \exp(|a_t^T (\theta_{t+1} - \theta_s)|) \hat{\mu}(a_t^T \theta_{t+1})} a_t^T (\bar{\theta}_t - \theta_s) \\
\leq \sqrt{e} \sum_{t = \tau+1}^{T} \sqrt{\hat{\mu}(a_t^T \theta_s)} \sqrt{\hat{\mu}(a_t^T \theta_{t+1})} a_t^T (\bar{\theta}_t - \theta_s) \\
\leq \sqrt{e} \sum_{t = \tau+1}^{T} \sqrt{\hat{\mu}(a_t^T \theta_s)} \sqrt{\hat{\mu}(a_t^T \theta_{t+1})} \|a_t\|_{\mathbf{W}^{-1}} \|\bar{\theta}_t - \theta_s\|_{\mathbf{W}}, \\
\leq e \sum_{t = \tau+1}^{T} \sqrt{\hat{\mu}(a_t^T \theta_s)} \sqrt{\hat{\mu}(a_t^T \theta_{t+1})} \|a_t\|_{\mathbf{W}^{-1}} \left(\|\bar{\theta}_t - \theta_s\|_{\mathbf{W}} + \|\bar{\theta}_t - \theta_s\|_{\mathbf{W}}\right) \\
\leq 2e \sqrt{\sigma_T(\delta)} \sum_{t = \tau+1}^{T} \sqrt{\hat{\mu}(a_t^T \theta_s)} \sqrt{\hat{\mu}(a_t^T \theta_{t+1})} \|a_t\|_{\mathbf{W}^{-1}} \\
\leq C \sqrt{d \log(T/\delta)} \sqrt{\sum_{t = \tau+1}^{T} \hat{\mu}(a_t^T \theta_s) \sum_{t = \tau+1}^{T} \hat{\mu}(a_t^T \theta_{t+1})} \|a_t\|_{\mathbf{W}^{-1}}^{2} \sqrt{d \log(1 + T/d)} \\
\leq C \sqrt{d \log(T/\delta)} \sqrt{d \log(1 + T/d)} \sum_{t = \tau+1}^{T} \hat{\mu}(a_t^T \theta_s) \text{ (Lemma 9)}.
\]
where Lemma 9 was used with $x_t = \sqrt{\mu(a_t^T \theta_{t+1})} a_t$ (and $\mu \leq 1$). From then, we can directly follow the proof of Theorem 1 from Abeille et al. (2021) (more precisely, follow the reasoning employed in their Section C.1 page 18) for which we extract that:

$$\sum_{t=\tau+1}^{T} \hat{\mu}(a_t^T \theta_*) \leq R_T + T\hat{\mu}(a_t^T \theta_*) .$$

Assembling the bounds on $R_2(T)$, $R_1(T)$ and $\sum_{t=\tau+1}^{T} \hat{\mu}(a_t^T \theta_*)$ we obtain that:

$$R(T) \leq C \kappa S^2 d^2 \log(T/\delta)^2 + CsD \log(T/\delta) \sqrt{R_T + T\hat{\mu}(a_t^T \theta_*)} .$$

Because $x^2 - bx - c \leq 0 \Rightarrow x^2 \leq 2b^2 + 2c$ we have:

$$R(T) \leq CsD \log(T/\delta) \sqrt{R_T + T\mu(a_t^T \theta_*)} + C \kappa S^2 d^2 \log(T/\delta)^2 ,$$

which concludes the proof.

**Remark 2.** The scaling w.r.t $S$ of the regret’s second-order term is driven by the length $\tau$ of the warm-up phase. As anticipated in Remark 1 this scaling is reduced when $\|\theta_*\| \leq S$ which often happens in practice. In this case, we obtain a second-order term which exactly matches the one of Abeille et al. (2021).

### D.2 The TS-ECOLog algorithm

In this section we introduce the TS version of OFU-ECOLog whose pseudo-code is provided in Algorithm 3.

**Algorithm 3 TS-ECOLog**

**input:** failure level $\delta$, warm-up length $\tau$, distribution $D^{TS}$

Set $\Theta \leftarrow \text{WarmUp}(\tau)$ (see Procedure 1).

Initialize $\theta_{\tau+1} \in \Theta, W_{\tau+1} \leftarrow \mathbf{I}_d$.

for $t \geq \tau + 1$ do

Set reject $\leftarrow$ true

while reject do

Sample $\eta \sim D^{TS}$, let $\hat{\theta}_t = \theta_t + \sigma_t(\delta) W_t^{-1/2} \eta$.

If $\hat{\theta}_t \in \Theta$ set reject $\leftarrow$ false

end while

Play $a_t \in \text{arg max}_{a \in A} a^T \hat{\theta}_t$.

Observe reward $r_{t+1}$, construct loss $\ell_{t+1}(\theta) = \ell(a_t^T \theta, r_{t+1})$.

Compute $(\theta_{t+1}, W_{t+1}) \leftarrow \text{ECOLog}(1/t, \Theta, \ell_{t+1}, W_t, \theta_t)$ (see Procedure 2).

end for

The algorithm display little novelty compared to the linear case studied by Agrawal and Goyal (2013); Abeille and Lazaric (2017). The only difference is a rejection sampling step on $\Theta$. The analysis is also similar, up to minor modifications. The following statement provides a regret guarantee for TS-ECOLog.

**Theorem 5.** Let $\delta \in (0, 1]$ and $D^{TS}$ a distribution satisfying Definition 1 of Abeille and Lazaric (2017). Setting $\tau = C \kappa S^6 d^2 \log(T/\delta)^2$ ensures that the regret of TS-ECOLog($\delta, \tau, D^{TS}$) satisfies with probability at least $1 - \delta$:

$$\text{Regret}(T) \leq CsD \delta^{3/2} \log(T/\delta) \sqrt{\mu(a_t^T \theta_*)} + C \kappa S^6 d^2 \log(T/\delta)^2 .$$

**Proof.** According to Proposition 3 (its detailed version in Appendix C.4) setting $\tau = C \kappa S^6 d^2 \log(T/\delta)$ ensures:

$$P \left( \theta_* \in \Theta \text{ and } \|\theta_t - \theta_*\|_{W_t}^2 \leq \sigma_t(\delta) \text{ for all } t \geq \tau + 1 \right) \geq 1 - 2\delta .$$

As in the proof of Theorem 1 we assume that the above event, denoted $E_\delta$, holds.
We decompose the regret as:

\[
\text{Regret}(T) \leq \tau + \sum_{t=\tau+1}^T \mu(a_t^\top \theta_*) - \mu(a_t^\top \tilde{\theta}_t)
\]

\[
= \tau + \sum_{t=\tau+1}^T \mu(a_t^\top \theta_*) - \mu(a_t^\top \tilde{\theta}_t) + \sum_{t=\tau+1}^T \mu(a_t^\top \tilde{\theta}_t) - \mu(a_t^\top \theta_*)
\]

\[
\leq \mathcal{C} \kappa S^6 d^2 \log(T/\delta)^2 + R^{TS}(T) + R^{\text{PRED}}(T).
\]

Above, we defined \(R^{\text{TS}}(T) = \sum_{t=\tau+1}^T \mu(a_t^\top \theta_*) - \mu(a_t^\top \tilde{\theta}_t)\) and \(R^{\text{PRED}}(T) = \sum_{t=\tau+1}^T \mu(a_t^\top \tilde{\theta}_t) - \mu(a_t^\top \theta_*)\). To bound \(R^{\text{PRED}}(T)\) one can directly follow the strategy employed in Appendix D.1. The only difference comes from the radius of the “effective” confidence set that is used - inflated by \(\sqrt{d}\) because of the concentration properties of \(\mathcal{D}^{TS}\). This leads to:

\[
R^{\text{PRED}}(T) \leq \mathcal{C} Sd^{3/2} \log(T/\delta) \sqrt{T \mu(a_*,\theta_*)} + \mathcal{C} \kappa S^2 d^3 \log(T/\delta)^2.
\]

We now turn to \(R^{TS}(T)\). Following Abeille and Lazaric (2017) we denote \(J(\theta) = \max_{a \in A} a^\top \theta\). We have:

\[
R^{TS}(T) = \sum_{t=\tau+1}^T \mu(a_t^\top \theta_*) - \mu(a_t^\top \tilde{\theta}_t)
\]

\[
= \sum_{t=\tau+1}^T \alpha(a_t^\top \theta_*, a_t^\top \tilde{\theta}_t)(a_t^\top \theta_* - a_t^\top \tilde{\theta}_t) \quad \text{(exact first-order Taylor)}
\]

\[
= \sum_{t=\tau+1}^T \alpha(J(\theta_*), J(\tilde{\theta}_t))(J(\theta_*) - J(\tilde{\theta}_t)) \quad \text{(def. of } J) \quad (34)
\]

By convexity of \(J\) along with the computations of its sub-gradients (see Section C of Abeille and Lazaric (2017));

\[
|J(\theta_*) - J(\tilde{\theta}_t)| \leq \max \left\{ |\nabla J(\theta_*)^\top (\theta_* - \tilde{\theta}_t)|, |\nabla J(\tilde{\theta}_t)^\top (\theta_* - \tilde{\theta}_t)| \right\} \quad \text{(convexity of } J)
\]

\[
\leq \max \left\{ |a_t^\top (\theta_* - \tilde{\theta}_t)|, |a_t^\top (\theta_* - \tilde{\theta}_t)| \right\} \quad \text{(Lemma 9 of Abeille et al. (2021))}
\]

\[
\leq \text{diam}_A(\Theta) \quad \text{(Proposition 5)}
\]

Therefore:

\[
\alpha(J(\theta_*), J(\tilde{\theta}_t)) = \int_{v=0}^1 \hat{\mu}(J(\theta_*)) + v(J(\tilde{\theta}_t) - J(\theta_*)) dv
\]

\[
\leq \hat{\mu}(J(\theta_*)) \int_{v=0}^1 \exp(v|J(\tilde{\theta}_t) - J(\theta_*)|) dv \quad (\text{Lemma 9 of Abeille et al. (2021)})
\]

\[
\leq \hat{\mu}(J(\theta_*)) \int_{v=0}^1 \exp(v) dv \quad (|J(\theta_*) - J(\tilde{\theta}_t) \leq 1)
\]

\[
\leq 2\hat{\mu}(J(\theta_*)).
\]

Plugging the above inequality in Equation (34) yields:

\[
R^{TS}(T) \leq 2\hat{\mu}(J(\theta_*)) \sum_{t=\tau+1}^T J(\theta_*) - J(\tilde{\theta}_t)
\]

\[
= 2\hat{\mu}(a_\tau^\top \theta_*) \sum_{t=\tau+1}^T J(\theta_*) - J(\tilde{\theta}_t).
\]
From then on we can follow the proof of Abeille and Lazaric (2017) which in the linear case studies exactly \( \sum_t J(\theta_t) - J(\theta_1) \). Directly following their line of proof yields \( \sum_t J(\theta_t) - J(\theta_1) \leq C \sqrt{T} \sqrt{\sigma_T(\delta)} \sum_t \|a_t\|_W^{-1} + \sqrt{T} \). This concludes the proof since \( \sigma_T(\delta) \leq C S^2 d \log(T/\delta) \) and:

\[
\mu(a^T_t \theta_t) \sum_{t=\tau+1}^T \|a_t\|_W^{-1} = \sqrt{\mu(a^T_t \theta_t) \sum_{t=\tau+1}^T \sqrt{\mu(a^T_t \theta_t)} \|a_t\|_W^{-1}}
\]

\[
\leq C \sqrt{\mu(a^T_t \theta_t) \sum_{t=\tau+1}^T \sqrt{\mu(a^T_t \theta_{t+1})} \sqrt{\exp(|a^T_t(\theta_t - \theta_{t+1})|)} \|a_t\|_W^{-1}}
\]

\[
\leq C \sqrt{\mu(a^T_t \theta_t) \sum_{t=\tau+1}^T \sqrt{\mu(a^T_t \theta_{t+1})} \sqrt{\exp(2 diam(\Theta))} \|a_t\|_W^{-1}} (\theta_{t+1}, \theta_t \in \Theta)
\]

\[
\leq C \sqrt{\mu(a^T_t \theta_t) \sum_{t=\tau+1}^T \sqrt{\mu(a^T_t \theta_{t+1})} \|a_t\|_W^{-1}} (\text{diam}(\Theta) \leq 1)
\]

\[
\leq C \sqrt{T \mu(a^T_t \theta_t) \sqrt{d \log(T)}}. \quad \text{(Cauchy-Schwarz, Lemma 9)}
\]

\[\square\]

D.3 Proof of Theorem 2

Theorem 2. Let \( \delta \in (0, 1) \). With probability at least \( 1 - \delta \) the regret of ada-OFU-ECOLog(\( \delta \)) satisfies:

\[
\text{Regret}(T) \leq CSd \sqrt{\sum_{t=1}^T \mu(a^T_{t,t} \theta_*) \log(\frac{N}{\delta})} + CS^2 \kappa d^2 \log(T/\delta)^2,
\]

where \( a_{*,t} = \arg\max_{a \in A_t} \log(a^T \theta_*) \).

Algorithm 2 ada-OFU-ECOLog

**input:** failure level \( \delta \).

Initialize \( \Theta_1 = \{\|\theta\| \leq S\}, C_1(\delta) \leftarrow \Theta_1, \theta_1 \in \Theta, W_1 \leftarrow I_d \) and \( H_1 \leftarrow \emptyset \).

for \( t \geq 1 \) do

Play \( a_t \in \arg\max_{a \in A_t} \max_{\theta \in C(\delta)} a^T \theta \), observe reward \( r_{t+1} \).

Compute the estimators \( \hat{\theta}_t^0, \hat{\theta}_t^1 \) (see Equation (8)) and \( \hat{\theta}_t \).

if \( \hat{\mu}(a^T_t \hat{\theta}_t) \leq 2 \hat{\mu}(a^T_t \theta_t^0) \) then

Form the loss \( \ell_{t+1} \) and compute \( \hat{\ell}_{t+1}, W_{t+1} \leftarrow \text{ECOLog}(1/t, \Theta_t, \ell_{t+1}, W_t, \ell_t) \).

Compute \( C_{t+1}(\delta) \leftarrow \left\{ \|\theta - \theta_{t+1}\|^2_{W_{t+1}} \leq \eta_t(\delta) \right\}, \) set \( H_{t+1} \leftarrow H_t \). \( \triangleright \eta_t(\delta) \) is defined in Equation (15)

else

Set \( H_{t+1} \leftarrow H_t \cup \{a_t, r_{t+1}\} \) and compute \( \hat{\ell}_{t+1}^H = \arg\min_{\ell(a^T \theta, r) + \gamma_t(\delta) \|\theta\|^2} \sum_{r \in H_{t+1}} \ell(a^T \theta, r) \).

Update \( V_t^H \leftarrow \sum_{r \in H_{t+1}} a^T \theta a^T \theta + \gamma_t(\delta) I_d \), \( r_{t+1} \leftarrow \theta_t \) and \( W_{t+1} \leftarrow W_t \).

Compute \( \Theta_{t+1} \leftarrow \left\{ \|\theta - \theta_{t+1}\|^2_{V_t^H} \leq \beta_t(\delta) \right\} \cap \Theta_1 \). \( \triangleright \beta_t(\delta) \) is defined in Equation (12)

end if

end for

Proof. We denote \( T \) the set of rounds at which condition \( C_1 \) breaks. Formally:

\[
T := \{ t \in [T], \mu(a_t^T \hat{\theta}_t) \geq 2 \hat{\mu}(a_t^T \theta_t^0) \text{ or } \hat{\mu}(a_t^T \theta_t^0) \geq 2 \hat{\mu}(a_t^T \theta_t) \}.
\]

We claim the following result bounding the cardinality of \( T \). The proof is deferred to Appendix D.3.1.

Lemma 8. The following inequality holds:

\[
|T| \leq CS^2 \kappa d^2 \log(T/\delta)^2.
\]
We follow a naive (but sufficient) bounding strategy. For rounds $t \in \mathcal{T}$ we crudely bound the instantaneous regret by its maximal value ($e.g.$ 1):

$$
\text{Regret}(T) \leq |\mathcal{T}| + \sum_{t \in |\mathcal{T}| T} \hat{\mu}(a_t \theta^*) - \mu(a_t \theta^*)
$$

$$
\leq \mathcal{C} S^6 \kappa d^2 \log(T/\delta)^2 + R_T
$$

(\text{Lemma 8})

where $R_T := \sum_{t \in T} \hat{\mu}(a_t \theta^*) - \mu(a_t \theta^*)$. In the following, we denote for $t \notin \mathcal{T}$:

$$(a_t, \hat{\theta}_t) \in \arg\max_{\mathcal{A}_t, C_t(\theta)} a_t \theta.$$

where $C_t(\delta) = \{ \theta, \|\theta - \theta\|_w^2 \leq \eta_t(\delta) \}$ and $\eta_t(\delta)$ is defined in Equation (15). In the following, we assume that the following event holds:

$$E_\delta = \{ t \in |\mathcal{T}| \mathcal{T}, \theta^* \in C_t(\delta) \cap \Theta_t \}$$

This happens with probability at least $1 - 2\delta$ according to Proposition 7. This implies that the couple $(a_t, \hat{\theta}_t)$ is optimistic. Formally: $a_t \theta^* \geq a_t \theta^*$. Therefore:

$$R(T) = \sum_{t \in |\mathcal{T}| T} \mu(a_t \theta^*) - \mu(a_t \theta^*)
$$

$$\leq \sum_{t \in |\mathcal{T}| T} \hat{\mu}(a_t \theta^*) - \mu(a_t \theta^*)
$$

(optimism, $\mu \nearrow$)

$$= R_1(T) + R_2(T).$$

The bound on $R_2(T)$ is directly extracted from the proof of Theorem 1 presented in Appendix D.1.

$$R_2(T) \leq \mathcal{C} d^2 \kappa S^2 \log(T/\delta)^2.$$ 

The story is slightly different for $R_1(T)$ and the proof laid out in Appendix D.1 needs to be slightly adapted. We need to differentiate the rounds where $\hat{\mu}(a_t \theta^*) \leq \hat{\mu}(a_t \theta_{t+1})$ and the rounds where $\hat{\mu}(a_t \theta^*) \geq \hat{\mu}(a_t \theta_{t+1})$. In what follows we focus only on the latter (for the former we can directly adapt the approach laid out in Appendix D.1).

$$R_1(T) = \sum_{t \in |\mathcal{T}| T} \hat{\mu}(a_t \theta^*) a_t \theta^* (\hat{\theta}_t - \theta^*)
$$

$$\leq \sum_{t \in |\mathcal{T}| T} \hat{\mu}(a_t \theta^*) a_t \theta^* (\hat{\theta}_t - \theta^*) (a_t \theta^* - a_t \theta_{t+1})$$

(Taylor, $|\hat{\mu}| \leq 1)$

$$\leq \sum_{t \in |\mathcal{T}| T} \hat{\mu}(a_t \theta^*) \|a_t \theta^* - \theta^*\|_w \|\hat{\theta}_t - \theta^*\|_w + \|a_t \theta^* - a_t \theta_{t+1}\|_w \|\theta_{t+1} - \theta^*\|_w$$

(Cauchy-Schwarz)

$$\leq \mathcal{C} \sqrt{\eta_T(\delta)} \sum_{t \in |\mathcal{T}| T} \hat{\mu}(a_t \theta^*) \|a_t \theta^* - \theta^*\|_w + \mathcal{C} \sqrt{\eta_T(\delta)} \sum_{t \in |\mathcal{T}| T} \|a_t \theta^* - a_t \theta_{t+1}\|_w \|\theta_{t+1} - \theta^*\|_w$$

($\hat{\theta}_t \in C_t(\delta), E_\delta$ holds)

$$\leq \mathcal{C} \sqrt{\eta_T(\delta)} \sum_{t \in |\mathcal{T}| T} \hat{\mu}(a_t \theta^*) \|a_t \theta^* - \theta^*\|_w + \mathcal{C} \eta_T(\delta) \sum_{t \in |\mathcal{T}| T} \|a_t \theta^* - a_t \theta_{t+1}\|_w \|\theta_{t+1} - \theta^*\|_w$$

($\mathcal{W}_t \geq \mathcal{W}_{t+1}$)

$$\leq \mathcal{C} \sqrt{\eta_T(\delta)} \sum_{t \in |\mathcal{T}| T} \hat{\mu}(a_t \theta^*) \|a_t \theta^* - \theta^*\|_w + \mathcal{C} \eta_T(\delta) \sum_{t \in |\mathcal{T}| T} \|a_t \theta^* - a_t \theta_{t+1}\|_w \|\theta_{t+1} - \theta^*\|_w$$

($\theta_{t+1} \in C_{t+1}(\delta), E_\delta$ holds)
The second term in the above inequality is bounded exactly as in $R_2(T)$; this yields:
\[
R_1(T) \leq \mathcal{C}\sqrt{\eta T(\delta)} \sum_{t \in |T|} \mu(a_t^T \tilde{\theta}_{t+1}) a_t \|W\|_{W_t^{-1}} + \mathcal{C} \kappa S^2 d^2 \log(T)^2
\]  
(cf. bound on $R_2(T)$)
\[
\leq \mathcal{C}\sqrt{\eta T(\delta)} \sqrt{\sum_{t \in |T|} \mu(a_t^T \tilde{\theta}_{t+1})} \sqrt{\sum_{t \in |T|} \mu(a_t^T \tilde{\theta}_{t+1}) a_t^2 \|W\|_{W_t^{-1}}} + \mathcal{C} \kappa S^2 d^2 \log(T/\delta)^2
\]  
(Cauchy-Schwarz)
\[
\leq \mathcal{C}Sd \log(T/\delta) \sqrt{\sum_{t \in |T|} \mu(a_t^T \theta_t)} + \mathcal{C} \kappa S^2 d^2 \log(T/\delta)^2
\]  
(Lemma 9)
\[
\leq \mathcal{C}Sd \log(T/\delta) \sqrt{\sum_{t \in |T|} \mu(a_t^T \theta_t)} + \mathcal{C} \kappa S^2 d^2 \log(T/\delta)^2
\]  
(by hyp.)

Again, by following the proof of Theorem 1 from Abeille et al. (2021) we get that:
\[
\sum_{t \in |T|} \mu(a_t^T \theta_t) \leq R_T + \sum_{t \in |T|} \mu(a_t^T \theta_t).
\]

Assembling the different bounds and solving the implicit inequation on $R_T$ yields the announced result.

D.3.1 Proof of Lemma 8

Lemma 8. The following inequality holds:
\[
|T| \leq \mathcal{C}S^6 \kappa d^2 \log(T/\delta)^2.
\]

Proof. Denote for $u \in \{0,1\}$:
\[
T_u := \{t \in |T|, \mu(a_t^T \tilde{\theta}_t) \geq 2 \mu(a_t^T \theta^u_t)\},
\]
so that $T = T_0 \cup T_1$. By Abeille et al. (2021, Lemma 9) we know that:
\[
\mu(a_t^T \tilde{\theta}_t) \leq \mu(a_t^T \theta^u_t) \exp(|a_t^T (\tilde{\theta}_t - \theta^u_t)|)
\]
Therefore by straight-forward manipulations:
\[
t \in T \implies \exists u \in \{0,1\} \text{ s.t. } |a_t^T (\tilde{\theta}_t - \theta^u_t)| \geq \log(2).
\]  
(35)

We can now bound $|T|$ thanks to the form of $\Theta_t$ (which contains $\tilde{\theta}_t$ and $\theta^u_t$ by construction) and the Elliptical Potential lemma.
\[
|T| \log(2)^2 \leq \sum_{t \in T} |a_t^T (\tilde{\theta}_t - \theta^u_t)|^2
\]
\[
\leq \sum_{t \in T} |a_t|_{(V^H)^{-1}} \|\tilde{\theta}_t - \theta^u_t\|_{V_t^H}^2
\]  
(Cauchy-Schwarz)
\[
\leq 4 \beta_T(\delta) \sum_{t \in T} |a_t|_{(V^H)^{-1}} \|\tilde{\theta}_t - \theta^u_t\|_{V_t^H}
\]
\[
\leq 8 \kappa \beta_T(\delta) d \log(T)
\]  
(Lemma 9)

We applied Lemma 9 with $x_s = a_s / \sqrt{T}$, and after checking that in Algorithm 2 the matrix $V_t^H$ is indeed updated in rounds $t \in T$. This conclude the proof since $\beta_t(\delta) \leq \mathcal{C}S^6 d \log(T/\delta)$.

\[\square\]
E Computational Costs

E.1 Proof of Propositions 1 and 4

The goal of this section is to examine the per-round complexity of the algorithms laid out in the main paper.

E.1.1 Per-Round Cost of ECOLog

We start by the main computational bottleneck of our approach, which is the ECOLog procedure (see its sequential form in Algorithm 4). It involves computing $\theta'_{t+1}$ - an $\varepsilon_t$-approximation (in $\ell_2$-norm) of $\theta_{t+1}$, and updating the matrix $W_{t+1}$ (along with its inverse which will be used for the planning mechanism). We claim the following result, a slightly more detailed version of Proposition 2 in the main text.

Proposition 8. Fix $t \in \mathbb{N}^+$. Assume that $\Theta_t$ is a bounded and closed ellipsoid and $\varepsilon_t > 0$. Completing round $t$ of ECOLog can be done within $O(d^2 \log(\text{diam}(\Theta_t))/\varepsilon_t^2)$ operations.

Proof. Given $\theta'_{t+1}$ the matrix $W_{t+1}$ can be updated at cost $O(d^2)$ since:

$$W_{t+1} = W_t + \mu(a_t^T \theta'_{t+1})a_t a_t^T.$$

The cost of maintaining $W_{t+1}^{-1}$ is the same thanks to the Sherman-Morrison formula. The main computational complexity therefore stems from the computation of $\theta'_{t+1}$. Recall:

$$\theta_{t+1} = \arg \min_{\theta \in \Theta_t} \frac{1}{2 + D} \|\theta - \theta'\|^2_{W_t} + \ell_{t+1}(\theta),$$

where $D \geq \text{diam}_A(\Theta_t)$. Let $W_t = L_t L_t^T$ the Cholesky decomposition of $W_t$ (it exists since $W_t$ is p.s.d). By denoting $z_t = L_t^T \theta'$, performing the change of variable $z \leftarrow L_t^T \theta$ and removing constants we obtain:

$$\theta_{t+1} = L_t^T \arg \min_{L_t^T z \in \Theta_t} \left( L_{t+1}(z) := \frac{1}{2 + D} \|z\|^2 + \frac{2}{D} z^T z_t + \ell_{t+1}(L_t^T z) \right).$$

By direct computations:

$$\nabla^2 L_{t+1}(z) = (1 + D/2)^{-1} I_d + \mu(a_t^T L_t^T z) L_t^{-1} a_t a_t^T L_t^{-T}.$$

proving that for all $z \in \mathbb{R}^d$ (using the fact that $\mu \in [0, 1/4]$ and $W_t \succeq I_d$):

$$0 < (1 + D/2)^{-1} \preceq \nabla^2 L_{t+1}(z) \preceq (1 + D/2)^{-1} + 1/4.$$

The function $L_{t+1}(z)$ is therefore strongly convex and $(5/4 + D/8)^{-1}$ well-conditioned. Furthermore, note the convexity of the constraint $\{z, L_t^T z \in \Theta_t\}$ since $\Theta_t$ itself is convex.

Let $\theta'_{t+1}$ be returned by the Projected Gradient Descent algorithm (see (Hazan, 2016, Algorithm 2) for instance) ran for $T$ steps, where:

$$T = \left(9/4 + D/8\right) \log(\text{diam}(\Theta_t))/\varepsilon_t.$$

By Lemma 12 this ensures that:

$$\|\theta_{t+1} - \theta'_{t+1}\| \leq \varepsilon_t,$$

which is enough to complete round $t$ of the ECOLog procedure. Because the gradients of $L_{t+1}(\theta)$ only take $O(d^2)$ operations to compute, the cost of running the Projected Gradient Descent algorithm for $T$ rounds is $O(T(d^2 + \text{proj}(\Theta_t)))$. The quantity $\text{proj}(\Theta_t)$ is the cost of projection the estimate on the set $\{L_t^{-T} z \in \Theta_t\}$. This constraint set is ellipsoidal since $\Theta_t$ is an ellipsoid (by assumption). Projecting on this set therefore boils down to solving a one-dimensional convex problem (see Lemma 13). Similarly, this program is solved to accuracy $\varepsilon$ in $O(d^2 \log(1/\varepsilon))$ (it involves some matrix-vector multiplications and triangular inverse solving, hence the $d^2$ dependency). To finish the proof we are therefore left with evaluating the cost of computing the Cholesky factor $L_t$. This quantity can be maintained online and updated at cost $O(d^2)$ thanks to the rank-one nature of $W_t$'s update (see for instance Golub and van Loan (2013, Section 6.5.4)).
E.1.2 Proof of Proposition 1

Proposition 1 (Computational Cost). Let $|A| = K < \infty$. Each round $t$ of OFU-ECOLog can be completed within $O(Kd^2 + d^2 \log(t)^2)$ operations.

Proof. Recall that in OFU-ECOLog we have $\Theta_t = \Theta$ where $D = 1$ satisfies $D \geq \text{diam}_A(\Theta)$ (see Proposition 5) and $\varepsilon_t = 1/t$. Easy computations further show that $\text{diam}(\Theta) \leq \text{poly}(S)$; for instance, a crude bound yields that for all $\theta_1, \theta_2 \in \Theta$

\[
\|\theta_1 - \theta_2\|^2 \leq \lambda_t(\delta)^{-1} \|\theta_1 - \theta_2\|^2_{\mathbf{V}_t}
\]

\[
\leq 4\lambda_t(\delta)^{-1} \beta_t(\delta) = \text{poly}(S) \quad (\theta_1, \theta_2 \in \Theta)
\]

(see Equations (10) and (12))

Proposition 8 hence ensures that the cost running the ECOLog routine at round $t$ of OFU-ECOLog is at most $c d^2 \log(\text{poly}(S)t)^2$. The optimistic planning mechanism requires performing $K$ matrix-vector products, which cost is $O(Kd^2)$. This finishes the proof.

Remark. The proof discards the cost of the warm-up; its only computational bottleneck is the computation of $\hat{\theta}_t$. This happens only once and boils down to the minimization of a well-conditioned (after preconditioning by $\mathbf{V}_t$) convex function - which is therefore cheap, typically $O(\tau \log(T))$ where $\tau$ is the length of the warm-up.

E.1.3 Proof of Proposition 4

Proposition 4. The per-round computational cost of Algorithm 2 is bounded by $O(\kappa + Kd^2 + d^2 \log(T)^2)$.

Proof. The proof is essentially the same as for Proposition 1. The main difference is the value of $\text{diam}_A(\Theta)$; it is now bounded by $\text{poly}(S)$ (by using a similar argument that in Appendix E.1.2 when we bounded $\text{diam}(\Theta)$). As discussed in the main text there is however an additional cost inherited from the computations of $\hat{\theta}_t^H$. This requires minimizing a well-conditioned (after preconditioning by $\mathbf{V}_t^H$) convex function which gradients are computed at $O(d|\mathcal{H}_t|)$ cost. Lemma 8 proves that $|\mathcal{H}_t| \leq \kappa$; therefore the computational overhead is $O(\kappa d \log(T))$.

Note that precisely because of Lemma 8, it turns out that this extra-cost only needs to be paid at most $\approx \kappa$ times (and not at every round as suggested by Proposition 4).

E.2 Computational Costs of Other Approaches

We briefly discuss the computational cost we announced in Table 1 for GLM-UCB Filippi et al. (2010) and OFULog-r Abeille et al. (2021). Both require the computation of the MLE estimator:

\[
\hat{\theta}_{t+1} = \arg\min_{\theta} \left\{ L_{t+1}(\theta) := \frac{t}{s=1} \ell_{s+1}(\theta) + \lambda \|\theta\|^2 \right\}.
\]

An efficient way to solve $\hat{\theta}_{t+1}$ to $\varepsilon$ accuracy (typically with $\varepsilon = 1/T$ to preserve regret guarantees) is to run a gradient descent (GD) algorithm with $\mathbf{V}_t$-preconditioning. This step is important as in all generality $L_{t+1}$ can be $1/t$ well-conditioned; running GD directly on $L_{t+1}$ will therefore require $O(t \log(1/\varepsilon))$ to reach $\varepsilon$-accuracy. Preconditioning allows to reduce this cost to $O(\log(1/\varepsilon))$. The cost of computing the gradient of $L_{t+1}$ (and its pre-conditioned version) is still high, typically $O(t)$ (more precisely, $O(d^2t)$ for the preconditioned version which involves matrix-vector multiplication). Overall, the cost of computing $\hat{\theta}_{t+1}$ to $\varepsilon$ accuracy is therefore $O(\kappa d^2 \log(1/\varepsilon))$.

For GLM-UCB a $O(d^2K)$ additional cost is to be added to account for the optimistic planning. Things are worse for OFULog-r as at round $t$ and for every arm $a \in A$ it needs to solve a convex program of the form:

\[
\max_{\theta} \left\{ a^T \theta \quad \text{s.t.} \quad L_{t+1}(\theta) \leq \gamma_t(\delta) \right\}.
\]

Projecting on the set $\{L_{t+1}(\theta) \leq \gamma_t(\delta)\}$ is as costly as computing of $\hat{\theta}_{t+1}$, hence the additional $\tilde{O}(Kd^2T)$ computational cost.
F  AUXILIARY RESULTS

The following version of the Elliptical Potential lemma (see, e.g, (Abbasi-Yadkori et al., 2011, Lemma 11)) is a direct consequence of (Faury et al., 2020, Lemma 15) along with the determinant-trace inequality (see Lemma 10).

Lemma 9 (Elliptical potential). Let $\lambda \geq 1$ and $\{x_s\}_{s=1}^{\infty}$ a sequence in $\mathbb{R}^d$ such that $\|x_s\| \leq X$ for all $s \in \mathbb{N}$. Further, define $V_t := \sum_{s=1}^{t} x_s x_s^T + \lambda I_d$. Then:

$$\sum_{t=1}^{T} \|x_t\|_{V_{t-1}}^2 \leq 2d(1+X^2) \log \left(1 + \frac{TX^2}{d\lambda}\right)$$

The following is extracted from (Abbasi-Yadkori et al., 2011, Lemma 10).

Lemma 10 (Determinant-Trace inequality). Let $\{x_s\}_{s=1}^{\infty}$ a sequence in $\mathbb{R}^d$ such that $\|x_s\| \leq X$ for all $s \in \mathbb{N}$, and let $\lambda$ be a non-negative scalar. For $t \geq 1$ define $V_t := \sum_{s=1}^{t} x_s x_s^T + \lambda I_d$. The following inequality holds:

$$\det(V_t) \leq (\lambda + tX^2/d)^d$$

The following statements are standard results from the convex optimization literature.

Lemma 11 (Section 4.2.3 of Boyd and Vandenberghe (2004)). Let $f : \mathbb{R}^d \to \mathbb{R}$ a differentiable and convex function and $C \subset \mathbb{R}^d$ a convex set. Further, denote:

$$x_0 := \arg \min_{x \in C} f(x) .$$

Then for any $y \in C$:

$$\nabla f(x_0)^T(y - x) \geq 0 .$$

Lemma 12. Let $f : \mathbb{R}^d \to \mathbb{R}$ a twice differentiable and strongly convex function such that for all $x \in \mathbb{R}^d$:

$$0 \preceq \alpha I_d \preceq \nabla^2 f(x) \preceq \beta I_d .$$

Let $C \subset \mathbb{R}^d$ a convex set, $x_0 = \arg \min_{C} f(x)$ and $\gamma = \alpha/\beta$. Let $x_{T+1}$ be the estimator returned by the projected gradient descent algorithm (Algorithm 2 in Hazan (2016)) with step-size $1/\beta$ run for $T$ rounds. For $\varepsilon > 0$ setting:

$$T = (1 + \gamma^{-1}) \log \left(\frac{\text{diam}(C)}{\varepsilon}\right) ,$$

ensures that $\|x_{T+1} - x_0\| \leq \varepsilon$.

Proof. The proof is standard in the convex optimization literature. We remind it briefly for completeness.

$$f(x_{T+1}) \geq f(x_0) + \nabla f(x_0)^T(x_{T+1} - x_0) + \frac{\alpha}{2} \|x_{T+1} - x_0\|^2$$

$$\geq f(x_0) + \frac{\alpha}{2} \|x_{T+1} - x_0\|^2$$  \hspace{1cm} (Lemma 11)

Furthermore by convexity:

$$f(x_{T+1}) \leq f(x_T) + \nabla f(x_T)^T(x_{T+1} - x_T) + \frac{\beta}{2} \|x_{T+1} - x_T\|^2$$

$$\leq f(x_T) + \nabla f(x_T)^T(x_0 - x_T) - \frac{\beta}{2} \|x_{T+1} - x_0\|^2 + \frac{\beta}{2} \|x_T - x_0\|^2$$

$$\leq f(x_0) - \frac{\beta}{2} \|x_0 - x_{T+1}\|^2 + \frac{\beta - \alpha}{2} \|x_T - x_0\|^2 .$$
The second to last inequality uses the definition of $x_{T+1}$ (given by the projected gradient descent algorithm). Plugging everything together yields:

$$
\|x_{T+1} - x_0\|^2 \leq \frac{\beta - \alpha}{\beta + \alpha} \|x_T - x_0\|^2 \\
\leq \left(\frac{\beta - \alpha}{\beta + \alpha}\right)^T \|x_1 - x_0\|^2 \\
\leq \left(1 - \frac{2\alpha}{\beta + \alpha}\right)^T \text{diam}(C)^2 \\
\leq \exp(-2T\alpha/(\beta + \alpha))\text{diam}(C)^2.
$$

Solving for $\|x_{T+1} - x_0\|^2 \leq \varepsilon^2$ yields the announced result. \hfill \square

**Lemma 13 (Ellipsoidal Projection).** Let $x \in \mathbb{R}^d$ and $A \in \mathbb{R}^{d \times d}$ a p.s.d matrix. Let $y$ be the projection of $x$ onto the set \{z, $\|z\|_A^2/2 \leq 1$\}. Then $y = (I_d + \lambda_* A^{-1})^{-1} x$ where $\lambda_*$ is the solution of the following one-dimensional strongly concave program:

$$
\lambda_* = \arg \max_{\lambda \geq 0} -2\lambda - x^T A^{1/2}(\lambda I_d + A)^{-1} A^{1/2} x.
$$

**Proof.** By definition of the projection onto a convex set:

$$
y := \arg \min_{z} \left\{ f(z) := \frac{1}{2} \|x - z\|^2 \right\}
$$

Introducing the Lagrangian $L(z, \lambda) := \|x - z\|^2/2 + \lambda(\|z\|_A^2/2 - 1)$ and by strong duality:

$$
f(y) = \min_{z} \max_{\lambda \geq 0} L(z, \lambda) \\
= \max_{\lambda \geq 0} \min_{z} L(z, \lambda).
$$

Denoting $z(\lambda) = \arg \min_z L(z, \lambda)$, direct computation yields that:

$$
z(\lambda) = (I_d + \lambda A^{-1})^{-1} x.
$$

Replacing into the dual problem, one obtains $y = z(\lambda_*)$ where $\lambda_*$ solves the program:

$$
\lambda_* = \arg \max_{\lambda \geq 0} -\lambda - x^T A^{1/2}(\lambda I_d + A)^{-1} A^{1/2} x/2.
$$

\hfill \square
G ADDITIONAL EXPERIMENTS

The results reported in Figure 2 complements Figure 1 from the main text, for $\text{LogB}$ instances of higher dimension and varying values of $\kappa$. As promised by the regret bounds, the improvement brought by $\text{ada-OFU-ECULog}$ over its statistically sub-optimal predecessors increases as $\kappa$ grows (i.e as the reward signal gets more non-linear). We did not evaluate the performances of $\text{OFULog-r}$ in this setting - it is unfortunately too computationally demanding to complete in reasonable time.
