Abstract
We consider the simplices

\[ K^A_n = \{ x \in \mathbb{R}^{n+1} : x_1 \geq x_2 \geq \cdots \geq x_{n+1}, x_1 - x_{n+1} \leq 1, x_1 + \cdots + x_{n+1} = 0 \} \]

and

\[ K^B_n = \{ x \in \mathbb{R}^n : 1 \geq x_1 \geq x_2 \geq \cdots \geq x_n \geq 0 \}, \]

which are called the Schläfli orthoschemes of types A and B, respectively. We describe the tangent cones at their \( j \)-faces and compute explicitly the sums of the conic intrinsic volumes of these tangent cones at all \( j \)-faces of \( K^A_n \) and \( K^B_n \). This setting contains sums of external and internal angles of \( K^A_n \) and \( K^B_n \) as special cases. The sums are evaluated in terms of Stirling numbers of both kinds. We generalize these results to finite products of Schläfli orthoschemes of type A and B and, as a probabilistic consequence, derive formulas for the expected number of \( j \)-faces of the Minkowski sums of the convex hulls of a finite number of Gaussian random walks and random bridges. Furthermore, we evaluate the analogous angle sums for the tangent cones of Weyl chambers of types A and B and finite products thereof.

1 Introduction

The Schlafli orthoscheme of type $B$ in $\mathbb{R}^n$, denoted by $K_n^B$, is the simplex spanned by the $n+1$ vertices

$$(0, 0, 0, \ldots, 0), \quad (1, 0, 0, \ldots, 0), \quad (1, 1, 0, \ldots, 0), \quad \ldots, \quad (1, 1, 1, \ldots, 1)$$

or, equivalently,

$$K_n^B = \{x \in \mathbb{R}^n : 1 \geq x_1 \geq x_2 \geq \cdots \geq x_n \geq 0\}.$$

The classical intrinsic volumes of $K_n^B$ were computed by Gao and Vitale [13] in order to evaluate the intrinsic volumes of the so-called Brownian motion body. The Schlafli orthoscheme of type $A$ in $\mathbb{R}^{n+1}$, denoted by $K_n^A$, was studied by Gao [12] in the context of Brownian bridges and is defined as the simplex spanned by the vertices $P_0, \ldots, P_{n+1}$, where $P_0 := (0, \ldots, 0)$ and

$$P_i = \left(1, \ldots, 1, 0, \ldots, 0\right) - \frac{i}{n+1} \left(1, 1, \ldots, 1\right)$$

for $i = 1, \ldots, n+1$. Equivalently, the Schlafli orthoscheme $K_n^A$ can be expressed as

$$K_n^A = \{x \in \mathbb{R}^{n+1} : x_1 \geq x_2 \geq \cdots \geq x_{n+1}, x_1 - x_{n+1} \leq 1, x_1 + \cdots + x_{n+1} = 0\}.$$

We will present further details on the probabilistic meaning of Schlafli orthoschemes in Sect. 3.1.

In the present paper, we evaluate certain angle sums or, more generally, sums of conic intrinsic volumes, of the Schlafli orthoschemes. For a polytope $P$, let $\mathcal{F}_j(P)$ denote the set of all $j$-dimensional faces of $P$. The tangent cone of $P$ at its $j$-dimensional face $F$ is the convex cone $T_F(P)$ defined by

$$T_F(P) = \{x \in \mathbb{R}^n : v + \varepsilon x \in P \text{ for some } \varepsilon > 0\},$$

where $v$ is any point in $F$ not belonging to a face of smaller dimension. We explicitly compute the conic intrinsic volumes of the tangent cones of the Schlafli orthoschemes at their $j$-dimensional faces and, in particular, the sum of the conic intrinsic volumes over all such faces. The $k$-th conic intrinsic volume of a convex cone $C$, denoted by $\nu_k(C)$, is a spherical or conic analogue of the usual intrinsic volume of a convex set and will be formally introduced in Sect. 2.2. Among other results, we will show that

$$\sum_{F \in \mathcal{F}_j(K_n^A)} \nu_k(T_F(K_n^A)) = \sum_{F \in \mathcal{F}_j(K_n^B)} \nu_k(T_F(K_n^B)) = \frac{j!}{n!} \left[\begin{array}{c} n+1 \\ k+1 \end{array}\right] \left\{\begin{array}{c} k+1 \\ j+1 \end{array}\right\}, \quad (1.1)$$

where the numbers $\left[\begin{array}{c} n \\ k \end{array}\right]$ and $\left\{\begin{array}{c} n \\ k \end{array}\right\}$ are the Stirling numbers of the first and second kind, respectively.
Furthermore, we will compute the analogous angle (and conic intrinsic volume) sums for the tangent cones of Weyl chambers of type $A$ and $B$ which are convex cones in $\mathbb{R}^n$ defined by

$$A^{(n)} := \{ x \in \mathbb{R}^n : x_1 \geq x_2 \geq \cdots \geq x_n \} \quad \text{and} \quad B^{(n)} := \{ x \in \mathbb{R}^n : x_1 \geq x_2 \geq \cdots \geq x_n \geq 0 \}.$$ 

The corresponding formulas are given by

$$\sum_{F \in \mathcal{F}_j(A^{(n)})} \nu_k(T_F(A^{(n)})) = \frac{j!}{n!} \left[ \begin{array}{c} n \\ k \end{array} \right] \left\{ \begin{array}{c} k \\ j \end{array} \right\},$$

$$\sum_{F \in \mathcal{F}_j(B^{(n)})} \nu_k(T_F(B^{(n)})) = \frac{2^n j!}{2^n n!} B[n, k] B[k, j],$$

where the numbers $B[n, k]$ and $B\{n, k\}$ denote the $B$-analogues of the Stirling numbers of the first and second kind, respectively, which we will formally introduce in Sect. 2.3.

An application of (1.1) and (1.2) to a problem of compressed sensing will be given in Sect. 3.6. Observe that in the special cases $k = n$ and $k = j$, (1.1) and (1.2) yield formulas for the sums of the internal and external angles of Schl"{a}fli orthoschemes and Weyl chambers.

We will generalize the above results to finite products of Schl"{a}fli orthoschemes and finite products of Weyl chambers leading to rather complicated formulas in terms of coefficients in the Taylor expansion of a certain function. The main results on angle and conic intrinsic volume sums will be stated in Sect. 3.2. As a probabilistic interpretation of these results, we consider convex hulls of Gaussian random walks and random bridges in Sect. 3.4. The expected numbers of $j$-faces of the convex hull of a single Gaussian random walk or a Gaussian bridge in $\mathbb{R}^d$ (even in a more general non-Gaussian setting) were already evaluated in [19]. Our general result on the angle sums of products of Schl"{a}fli orthoschemes yields a formula for the expected number of $j$-faces of the Minkowski sum of several convex hulls of Gaussian random walks or Gaussian random bridges.

It turns out that the tangent cones of the Schl"{a}fli orthoschemes (and of the Weyl chambers) are essentially products of Weyl chambers of type $A$ and $B$. We will derive (1.1) and (1.2) as a special case of a more general Proposition 3.8 stated in Sect. 3.3. This proposition gives a formula for the sum of the conic intrinsic volumes of a product of Weyl chambers in terms of the generalized Stirling numbers of the first and second kind. The main ingredients in the proof of this proposition are the known formulas for the conic intrinsic volumes of Weyl chambers; see e.g. [20, Thm. 4.2] or [14, Thm. 1.1].
2 Preliminaries

In this section we collect notation and facts from convex geometry and combinatorics. The reader may skip this section at first reading and return to it when necessary.

2.1 Facts from Convex Geometry

For a set \( M \subset \mathbb{R}^n \) denote by \( \text{lin} \ M \) (respectively, \( \text{aff} \ M \)) its linear (respectively, affine) hull, that is, the minimal linear (respectively, affine) subspace containing \( M \). Equivalently, \( \text{lin} \ M \) (respectively, \( \text{aff} \ M \)) is the set of all linear (respectively, affine) combinations of elements of \( M \). The relative interior of \( M \), denoted by \( \text{relint} \ M \), is the set of interior points of \( M \) relative to its affine hull \( \text{aff} \ M \). Let also \( \text{conv} \ M \) denote the convex hull of \( M \) which is defined as the minimal convex set containing \( M \), or equivalently

\[
\text{conv} \ M := \left\{ \sum_{i=1}^{m} \lambda_i x_i : m \in \mathbb{N}, \ x_1, \ldots, x_m \in M, \lambda_1, \ldots, \lambda_m \geq 0, \lambda_1 + \cdots + \lambda_m = 1 \right\}.
\]

Similarly, let \( \text{pos} \ M \) denote the positive (or conic) hull of \( M \):

\[
\text{pos} \ M := \left\{ \sum_{i=1}^{m} \lambda_i x_i : m \in \mathbb{N}, \ x_1, \ldots, x_m \in M, \lambda_1, \ldots, \lambda_m \geq 0 \right\}.
\]

A set \( C \subset \mathbb{R}^n \) is called a (convex) cone if \( \lambda_1 x_1 + \lambda_2 x_2 \in C \) for all \( x_1, x_2 \in C \) and \( \lambda_1, \lambda_2 \geq 0 \). Thus, \( \text{pos} \ M \) is the minimal cone containing \( M \). The dual cone of a cone \( C \subset \mathbb{R}^n \) is defined as

\[
C^\circ = \{ x \in \mathbb{R}^n : \langle x, y \rangle \leq 0 \text{ for all } y \in C \},
\]

where \( \langle \cdot, \cdot \rangle \) denotes the Euclidean scalar product. We will make use of the following simple duality relation that holds for arbitrary \( x_1, \ldots, x_m \in \mathbb{R}^n \):

\[
\text{pos} \{ x_1, \ldots, x_m \}^\circ = \{ v \in \mathbb{R}^n : \langle v, x_i \rangle \leq 0 \text{ for all } i = 1, \ldots, m \}. \tag{2.1}
\]

A polyhedral set \( P \subset \mathbb{R}^d \) is an intersection of finitely many closed half-spaces (whose boundaries need not pass through the origin). A bounded polyhedral set is called polytope. A polyhedral cone is an intersection of finitely many closed half-spaces whose boundaries contain the origin and therefore a special case of a polyhedral set. The faces of \( P \) (of arbitrary dimension) are obtained by replacing some of the half-spaces, whose intersection defines the polyhedral set, by their boundaries and taking the intersection. For \( k \in \{0, 1, \ldots, d\} \), we denote the set of \( k \)-dimensional faces of a
polyhedral set $P$ by $\mathcal{F}_k(P)$. Furthermore, we denote the number of $k$-faces of $P$ by $f_k(P) := |\mathcal{F}_k(P)|$. The tangent cone of $P$ at a face $F \in \mathcal{F}_k(P)$ is defined by

$$T_F(P) = \{ x \in \mathbb{R}^n : v + \varepsilon x \in P \text{ for some } \varepsilon > 0 \},$$

where $v$ is any point in the relative interior of $F$. It is known that this definition does not depend on the choice of $v$. The normal cone of $P$ at the face $F$ is defined as the dual of the tangent cone, that is

$$N_F(P) = T_F(P)^\circ = \{ w \in \mathbb{R}^n : \langle w, u \rangle \leq 0 \text{ for all } u \in T_F(P) \}.$$

It is easy to check that given a face $F$ of a cone $C$, the corresponding normal cone $N_F(C)$ satisfies $N_F(C) = (\ker F)^\perp \cap C^\circ$, where $L^\perp$ denotes the orthogonal complement of a linear subspace $L$.

### 2.2 Conic Intrinsic Volumes and Angles of Polyhedral Sets

Now let us introduce some geometric functionals of cones that we are going to consider. The following facts are mostly taken from [2, Sect. 2]; see also [23, Sect. 6.5]. At first, we define the conical intrinsic volumes which are the analogues of the usual intrinsic volumes in the setting of conic or spherical geometry.

Let $C \subset \mathbb{R}^n$ be a polyhedral cone and $g$ be an $n$-dimensional standard Gaussian random vector. Then, for $k \in \{0, \ldots, n\}$, the $k$-th conic intrinsic volume of $C$ is defined by

$$\nu_k(C) := \sum_{F \in \mathcal{F}_k(C)} \mathbb{P}(\Pi_C(g) \in \text{relint } F).$$

Here, $\Pi_C$ denotes the metric projection on $C$, that is $\Pi_C(x)$ is the vector in $C$ minimizing the Euclidean distance to $x \in \mathbb{R}^n$. The conic intrinsic volumes of a cone $C$ form a probability distribution on $\{0, 1, \ldots, \dim C\}$, that is

$$\sum_{k=0}^{\dim C} \nu_k(C) = 1 \quad \text{and} \quad \nu_k(C) \geq 0, \quad k = 0, \ldots, \dim C. \quad (2.2)$$

The Gauss–Bonnet formula [2, Cor. 4.4] states that

$$\sum_{k=0}^{\dim C} (-1)^k \nu_k(C) = 0 \quad (2.3)$$

for every cone $C$ that is not a linear subspace, which implies that

$$\sum_{k=1,3,5,\ldots} \nu_k(C) = \sum_{k=0,2,4,\ldots} \nu_k(C) = \frac{1}{2}. \quad (2.4)$$
Furthermore, the conic intrinsic volumes satisfy the product rule

\[ v_k(C_1 \times \cdots \times C_m) = \sum_{i_1+\cdots+i_m=k} v_{i_1}(C_1) \cdot \cdots \cdot v_{i_m}(C_m), \]

where \( C_1 \times \cdots \times C_m \) is the Cartesian product of \( C_1, \ldots, C_m \). The product rule implies that the generating polynomial of the intrinsic volumes of \( C \), defined by \( P_C(t) := \sum_{k=0}^{\dim C} v_k(C) t^k \), satisfies

\[ P_{C_1 \times \cdots \times C_m}(t) = P_{C_1}(t) \cdot \cdots \cdot P_{C_m}(t). \] (2.5)

For example, for an \( i \)-dimensional linear subspace \( L \), we have \( v_k(C \times L) = v_{k-i}(C) \) for \( k \geq i \).

The solid angle (or just angle) of a cone \( C \subset \mathbb{R}^n \) is defined as

\[ \alpha(C) := \mathbb{P}(Z \in C), \]

where \( Z \) is uniformly distributed on the unit sphere in the linear hull \( \text{lin} C \). Equivalently, we can take a random vector \( Z \) having a standard Gaussian distribution on the ambient linear subspace \( \text{lin} C \). For a \( d \)-dimensional cone \( C \subset \mathbb{R}^n \), where \( d \in \{1, \ldots, n\} \), the \( d \)-th conical intrinsic volume coincides with the solid angle of \( C \), that is

\[ v_d(C) = \alpha(C). \]

The internal angle of a polyhedral set \( P \) at a face \( F \) is defined as the solid angle of its tangent cone:

\[ \beta(F, P) := \alpha(T_F(P)). \]

The external angle of \( P \) at a face \( F \) is defined as the solid angle of the normal cone of \( F \) with respect to \( P \), that is

\[ \gamma(F, P) := \alpha(N_F(P)). \]

The conic intrinsic volumes of a cone \( C \subset \mathbb{R}^n \) can be computed in terms of the internal and external angles of its faces as follows:

\[ v_k(C) = \sum_{F \in F_k(C)} \alpha(F) \alpha(N_F(C)), \quad k \in \{0, \ldots, n\}. \] (2.6)

Let \( W_{n-k} \subset \mathbb{R}^n \) be random linear subspace having the uniform distribution on the Grassmann manifold of all \( (n - k) \)-dimensional linear subspaces. Then, following Grünbaum [16], the Grassmann angle \( \gamma_k(C) \) of a cone \( C \subset \mathbb{R}^n \) is defined as

\[ \gamma_k(C) := \mathbb{P}(W_{n-k} \cap C \neq \{0\}) \] (2.7)
for \( k \in \{0, \ldots, n\} \). The Grassmann angles do not depend on the dimension of the ambient space, that is, if we embed \( C \) in \( \mathbb{R}^N \) where \( N \geq n \), the Grassmann angle will be the same. If \( C \) is not a linear subspace, then \( \gamma_k(C) / 2 \) is also known as the \( k \)-th conic quermassintegral \( U_k(C) \) of \( C \), see [17, (1)–(4)], or as the half-tail functional \( h_{k+1}(C) \), see [3]. The conic intrinsic volumes and the Grassmann angles are known to satisfy the linear relation

\[
\gamma_k(C) = 2 \sum_{i=1,3,5,\ldots} u_{k+i}(C),
\]

see [2, (2.10)], provided \( C \) is not a linear subspace.

### 2.3 Stirling Numbers and Their Generating Functions

In this section, we are going to recall the definitions of various kinds of Stirling numbers and their generating functions. As mentioned in the introduction, these numbers appear in various results presented in this paper.

The (signless) Stirling number of the first kind \( \left[ n \atop k \right] \) is defined as the number of permutations of the set \( \{1, \ldots, n\} \) having exactly \( k \) cycles. Equivalently, these numbers can be defined as the coefficients of the polynomial

\[
t(t + 1) \cdot \ldots \cdot (t + n - 1) = \sum_{k=0}^{n} \left[ n \atop k \right] t^k
\]

for \( n \in \mathbb{N}_0 \), with the convention that \( \left[ n \atop k \right] = 0 \) for \( n \in \mathbb{N}_0, k \notin \{0, \ldots, n\} \), and \( \left[ 0 \atop 0 \right] = 1 \). By [22, (1.9),(1.15)], the Stirling numbers of the first kind can also be represented as the following sum:

\[
\left[ n \atop k \right] = \frac{n!}{k!} \sum_{m_1,\ldots,m_k \in \mathbb{N}; m_1+\ldots+m_k=n} \frac{1}{m_1 \cdot \ldots \cdot m_k}.
\]

The \( B \)-analogues of the Stirling numbers of the first kind, denoted by \( B[n, k] \), are defined as the coefficients of the polynomial

\[
(t + 1)(t + 3) \cdot \ldots \cdot (t + 2n - 1) = \sum_{k=0}^{n} B[n, k] t^k
\]

for \( n \in \mathbb{N}_0 \) and, by convention, \( B[n, k] = 0 \) for \( k \notin \{0, \ldots, n\} \). These numbers appear as entry A028338 in [24]. The exponential generating functions of the arrays
\( \binom{n}{k} \) and \( (B[n, k])_{n,k \geq 0} \) are given by

\[
\sum_{n=k}^{\infty} \binom{n}{k} \frac{t^n}{n!} = \frac{(-\log(1-t))^k}{k!}, \quad \sum_{k=0}^{\infty} \sum_{n=k}^{\infty} \binom{n}{k} \frac{t^n}{n!} y^k = (1-t)^{-y}
\]

(2.12)

and

\[
\sum_{k=0}^{\infty} \sum_{n=k}^{\infty} B[n, k] \frac{t^n}{n!} y^k = (1 - 2t)^{-(y+1)/2};
\]

(2.13)

see [14, Prop. 2.3] for the proof of (2.13).

The Stirling number of the second kind \( \left\{ \binom{n}{k} \right\} \) is defined as the number of partitions of the set \( \{1, \ldots, n\} \) into \( k \) non-empty subsets. Similarly to (2.10), the Stirling numbers of the second kind can be represented as the following sum:

\[
\left\{ \binom{n}{k} \right\} = \frac{n!}{k!} \sum_{m_1, \ldots, m_k \in \mathbb{N}} \frac{1}{m_1! \cdots m_k!};
\]

(2.14)

see [22, (1.9),(1.13)]. The \( B \)-analogues of the Stirling numbers of the second kind, denoted by \( B[n, k] \), are defined as

\[
B[n, k] = \sum_{m=k}^{n} 2^{m-k} \binom{n}{m} \binom{m}{k}.
\]

They appear as entry A039755 in [24] and were studied by Suter [25]. The exponential generating functions of the arrays \( \left\{ \binom{n}{k} \right\}_{n,k \geq 0} \) and \( (B[n, k])_{n,k \geq 0} \) are given by

\[
\sum_{n=k}^{\infty} \binom{n}{k} \frac{t^n}{n!} = (e^t - 1)^k, \quad \sum_{k=0}^{\infty} \sum_{n=k}^{\infty} \binom{n}{k} \frac{t^n}{n!} y^k = e^{(e^t-1)y}
\]

(2.15)

and

\[
\sum_{k=0}^{\infty} \sum_{n=k}^{\infty} B[n, k] \frac{t^n}{n!} y^k = e^{(e^t-1)/2} e^t;
\]

(2.16)
see [25, Thm. 4] for (2.16). The numbers $B\{n, k\}$ and $\binom{n}{k}$ appear as coefficients in the formulas

$$t^n = \sum_{k=0}^{n} (-1)^{n-k} B\{n, k\}(t+1)(t+3)\ldots(t+2k-1),$$

$$t^n = \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} t(t+1)\ldots(t+k-1);$$

see entry A039755 in [24] and also [4,5] for combinatorial proofs of both identities, which should be compared to the formulas (2.9) and (2.11) for $\binom{n}{k}$ and their $B$-analogues $B\{n, k\}$.

More generally, it is possible to define the $r$-Stirling numbers of the first and second kinds. For $r \in \mathbb{N}_0$, the (signless) $r$-Stirling number of the first kind, denoted by $[n\ k]_r$, is defined as the number of permutations of the set $\{1, \ldots, n\}$ having $k$ cycles such that the numbers $1, 2, \ldots, r$ are in distinct cycles; see [8, (1)]. The $r$-Stirling number of the second kind, denoted by $\{n\ k\}_r$, is defined as the number of partitions of the set $\{1, \ldots, n\}$ into $k$ non-empty disjoint subsets such that the numbers $1, 2, \ldots, r$ are in distinct subsets; see [8, (2)]. Obviously, for $r \in \{0, 1\}$, the $r$-Stirling numbers of the first and second kinds coincide with the classical Stirling numbers, respectively. The $r$-Stirling numbers were introduced by Carlitz [9,10] under the name weighted Stirling numbers.

The exponential generating functions in one and two variables of the $r$-Stirling numbers of the first kind are given by

$$\sum_{n=k}^{\infty} \sum_{r=0}^{\infty} \binom{n+r}{k+r}_r \frac{t^n}{n!} = \frac{(1-t)^{-r}(-\log(1-t))^k}{k!},$$

$$\sum_{k=0}^{\infty} \sum_{n=k}^{\infty} \binom{n+r}{k+r}_r \frac{t^n}{n!} y^k = \left(\frac{1}{1-t}\right)^{r+y};$$

see [8, (36),(37)]. For the $r$-Stirling numbers of the second kind they are given by

$$\sum_{n=k}^{\infty} \binom{n+r}{k+r}_r \frac{t^n}{n!} = e^{rt}(e^t-1)^k, \quad \sum_{k=0}^{\infty} \sum_{n=k}^{\infty} \binom{n+r}{k+r}_r \frac{t^n}{n!} y^k = e^{y(e^t-1)e^{rt}};$$

see [8, (38),(39)]. The $r$-Stirling numbers can equivalently be defined in terms of the regular Stirling numbers by

$$\binom{n}{k}_r = \sum_{m=0}^{n-k} \binom{n-r}{m} \binom{n-r-m}{k-r} r^m, \quad (2.19)$$
where \( r^m := r(r + 1) \cdots (r + m - 1) \) denotes the rising factorial, \( r^0 := 1 \), and

\[
\binom{n}{k}_r = \sum_{m=k-r}^{n-r} \binom{n-r}{m} \binom{m}{k-r} r^{n-r-m}, \tag{2.20}
\]

see [8, (27),(32)]. This even yields an analytic continuation of the \( r \)-Stirling numbers to non-integer (arbitrary complex) \( r \), given by

\[
\left[ n + \frac{r}{k + r} \right]_r = \sum_{m=0}^{n-k} \binom{n}{m} \binom{n-m}{k} r^m, \tag{2.21}
\]

and

\[
\{ n + \frac{r}{k + r} \}_r = \sum_{m=k}^{n} \binom{n}{m} \binom{m}{k} r^{n-m}. \tag{2.22}
\]

Note the following special values:

\[
\left[ \begin{array}{c} n \\ n \end{array} \right]_r = \{ \begin{array}{c} n \\ n \end{array} \}_r = 1, \quad n \geq r, \quad \text{and} \quad \left[ \begin{array}{c} n \\ k \end{array} \right]_r = \{ \begin{array}{c} n \\ k \end{array} \}_r = 0, \quad k \notin \{ r, \ldots, n \}.
\]

For \( r = 1/2 \), we observe the following relations between the \( r \)-Stirling numbers and the numbers \( B[n, k] \) and \( B\{n, k\} \):

\[
\left[ \begin{array}{c} n + 1/2 \\ k + 1/2 \end{array} \right]_{1/2} = 2^{k-n} B[n, k], \quad \left\{ \begin{array}{c} n + 1/2 \\ k + 1/2 \end{array} \right\}_{1/2} = 2^{k-n} B\{n, k\}. \tag{2.23}
\]

Both can easily be verified by comparing the generating functions. Let us also mention that besides the \( r \)-Stirling numbers there is another construction, the generalized two-parameter Stirling numbers \([21]\) (see also \([6]\)) containing Stirling numbers of both types and their \( B \)-analogues as special cases corresponding to the parameters \((d, a) = (1, 0)\) and \((d, a) = (2, 1)\), respectively. We will not use this general construction here.

### 3 Main Results

#### 3.1 Schläfli Orthoschemes

The polytopes we are interested in this paper are called Schläfli orthoschemes. As mentioned in the introduction, the Schläfli orthoscheme of type \( B \) in \( \mathbb{R}^n \) is defined as

\[
K^B_n := \text{conv } \{(0, 0, \ldots, 0), (1, 0, \ldots, 0), (1, 1, 0, \ldots, 0), \ldots, (1, 1, \ldots, 1)\} \cap \{x \in \mathbb{R}^n : 1 \geq x_1 \geq x_2 \geq \cdots \geq x_n \geq 0\}.
\]
Note that, for convenience, we set $K_B^0 := \{0\}$. Similarly, the Schläfli orthoscheme of type $A$ in $\mathbb{R}^{n+1}$ is defined as the convex hull of the $(n + 1)$-dimensional vectors $P_0, P_1, \ldots, P_{n+1}$, where $P_0 = (0, 0, \ldots, 0)$ and

$$P_i = \left(1, \ldots, 1, 0, \ldots, 0\right) - \frac{i}{n+1} \left(1, 1, \ldots, 1\right), \quad 1 \leq i \leq n + 1.$$

It is not difficult to check that

$$K_A^n = \{x \in \mathbb{R}^{n+1} : x_1 \geq x_2 \geq \cdots \geq x_{n+1}, x_1 - x_{n+1} \leq 1, x_1 + \cdots + x_{n+1} = 0\}.$$

Again, we put $K_A^0 = \{0\}$. The index shift from type $B$ to type $A$ will turn out to be convenient since $K_A^n \subset \mathbb{R}^{n+1}$ is an $n$-dimensional polytope. In fact, the Schläfli orthoschemes of type $A$ and type $B$ are simplices since they are convex hulls of $n + 1$ affinely independent vectors. The Schläfli orthoscheme of type $B$ was already considered by Gao and Vitale [13] who among other things evaluated the classical intrinsic volumes of $K_B^n$. Similar calculations for the Schläfli orthoscheme of type $A$ were made by Gao [12].

The definition of the Schläfli orthoscheme can be motivated by a connection to random walks and random bridges. In fact, consider Gaussian random matrices $G_B \in \mathbb{R}^{d \times n}$ and $G_A \in \mathbb{R}^{d \times (n+1)}$, that is, random matrices having independent and standard Gaussian distributed entries. Then $G_B K_B^n$ has the same distribution as the convex hull of a $d$-dimensional random walk $S_0 := 0, S_1, \ldots, S_n$ with Gaussian increments. Similarly, $G_A K_A^n$ has the same distribution as the convex hull of a $d$-dimensional Gaussian random bridge $\tilde{S}_0 := 0, \tilde{S}_1, \ldots, \tilde{S}_n, \tilde{S}_{n+1} = 0$ which is essentially a Gaussian random walk conditioned on the event that it returns to 0 in the $(n + 1)$-st step. We will explain these facts in Sect. 3.4 in more detail.

### 3.2 Sums of Conic Intrinsic Volumes in Weyl Chambers and Schläfli Orthoschemes

In this section, we state the main results of this paper concerning the sums of the conic intrinsic volumes of the tangent cones of Schläfli orthoschemes of type $A$ and $B$ and their products. The same is done for Weyl chambers of type $A$ and $B$ and their products. Our first result concerning the Schläfli orthoschemes of types $A$ and $B$ is the following theorem.

**Theorem 3.1** Let $j \in \{0, \ldots, n\}$ and $k \in \{0, \ldots, n\}$ be given. Then, it holds that

$$\sum_{F \in \mathcal{F}_j(K_B^n)} \nu_k(T_F(K_B^n)) = \sum_{F \in \mathcal{F}_j(K_A^n)} \nu_k(T_F(K_A^n)) = \frac{j!}{n!} \left[\begin{array}{c}n+1 \cr j+1\end{array}\right] \left[\begin{array}{c}k+1 \cr j+1\end{array}\right].$$

As a consequence, we can derive formulas for the sums of the internal and external angles of $K_B^n$ and $K_A^n$ at their $j$-faces $F$. 
Corollary 3.2 For \( j \in \{0, \ldots, n\} \), the sum of the internal angles is given by

\[
\sum_{F \in \mathcal{F}_j(K_B^n)} \alpha(T_F(K_B^n)) = \sum_{F \in \mathcal{F}_j(K_A^n)} \alpha(T_F(K_A^n)) = \frac{j!}{n!} \left\{ \frac{n+1}{j+1} \right\},
\]

while the sum of the external angles are given by

\[
\sum_{F \in \mathcal{F}_j(K_B^n)} \alpha(N_F(K_B^n)) = \sum_{F \in \mathcal{F}_j(K_A^n)} \alpha(N_F(K_A^n)) = \frac{j!}{n!} \left\{ \frac{n-j+1}{j+1} \right\}.
\]

Proof The sums of the internal angles follow from Theorem 3.1 with \( k = n \), since \( K_B^n \) and \( K_A^n \) are both \( n \)-dimensional polytopes. In the case of external angles, we use the fact that the maximal linear subspaces contained in both \( T_F(K_B^n) \) and \( T_F(K_A^n) \) are \( j \)-dimensional, which implies that \( \nu_j(T_F(K_B^n)) = \nu_{n-j}((T_F(K_B^n)^o) = \nu_{n-j}(N_F(K_B^n)) = \alpha(N_F(K_B^n)) \), and similarly for \( K_A^n \). Using Theorem 3.1 with \( k = j \) completes the proof.

We obtain similar results for the tangent cones of Weyl chambers of types A and B, which are the fundamental domains of the reflection groups of the respective type; see, e.g., [18]. More concretely, a Weyl chamber of type B (or \( B_n \)) is the polyhedral cone

\[
B(n) := \{ x \in \mathbb{R}^n : x_1 \geq x_2 \geq \cdots \geq x_n \geq 0 \}.
\]

The Weyl chamber of type A (or \( A_{n-1} \)) is the polyhedral cone

\[
A(n) := \{ x \in \mathbb{R}^n : x_1 \geq x_2 \geq \cdots \geq x_n \}.
\]

We set \( B(0) = A(0) = \{0\} \) for convenience.

Theorem 3.3 Let \( j \in \{0, \ldots, n\} \) and \( k \in \{0, \ldots, n\} \) be given. Then, it holds that

\[
\sum_{F \in \mathcal{F}_j(B(n))} \nu_k(T_F(B(n))) = \frac{j!}{n!} \left\{ \frac{n+1/2}{k+1/2} \right\} \left\{ \frac{k+1/2}{j+1/2} \right\} = \frac{2^j j!}{2^n n!} B[n, k] B[k, j],
\]

\[
\sum_{F \in \mathcal{F}_j(A(n))} \nu_k(T_F(A(n))) = \frac{j!}{n!} \left\{ \frac{n}{k} \right\} \left\{ \frac{k}{j} \right\}.
\]

Theorems 3.1 and 3.3 are special cases of Proposition 3.8 which we shall state in Sect. 3.3 and which gives a formula for sums of the conic intrinsic volumes of a mixed product of Weyl chambers of both types A and B. We will give an application of Theorems 3.1 and 3.3 to a problem of compressed sensing in Sect. 3.6.

It has been pointed to us by an anonymous referee that there is a similarity between Theorem 3.3 and the formulas, derived by Amelunxen and Lotz [2, Sect. 6.1.3], for the sums of \( k \)-th conic intrinsic volumes of \( j \)-dimensional faces in the fans of reflection.
arrangements. Despite the seeming similarity between the formulas, no direct connection between the quantities under interest seems to exist, the proofs are different and, in fact, even the right-hand sides of the formulas include Stirling numbers in a different order and cannot be reduced to each other in a simple way.

For $k = n$ and $k = j$, Theorem 3.3 yields the following corollary on the sums of internal and external angles of $B^{(n)}$ and $A^{(n)}$.

**Corollary 3.4** For $j \in \{0, \ldots, n\}$, the sums of internal angles of $B^{(n)}$ and $A^{(n)}$ are given by

$$\sum_{F \in \mathcal{F}_j(B^{(n)})} \alpha(T_F(B^{(n)})) = \frac{2^j j!}{2^n n!} B[n, j], \quad \sum_{F \in \mathcal{F}_j(A^{(n)})} \alpha(T_F(A^{(n)})) = \frac{j! \{n\}}{n! \{j\}},$$

while the sums of external angles are given by

$$\sum_{F \in \mathcal{F}_j(B^{(n)})} \alpha(N_F(B^{(n)})) = \frac{2^j j!}{2^n n!} B[n, j], \quad \sum_{F \in \mathcal{F}_j(A^{(n)})} \alpha(N_F(A^{(n)})) = \frac{j! \{n\}}{n! \{j\}}.$$

**Finite Products of Schl"afli Orthoschemes and Weyl Chambers**

The above theorems can be extended to finite products of Schl"afli orthoschemes and Weyl chambers. Let $b \in \mathbb{N}$ and define $K^B := K_{n_1}^B \times \cdots \times K_{n_b}^B$, $K^A := K_{n_1}^A \times \cdots \times K_{n_b}^A$ for $n_1, \ldots, n_b \in \mathbb{N}_0$ with $n := n_1 + \cdots + n_b$. Furthermore, for $d \in \{0, 1/2, 1\}$, let

$$R_d(k, j, b, (n_1, \ldots, n_b)) := [t^k \left[ x_1^{n_1} \cdots x_b^{n_b} \right] \left[ u^j \right]] \frac{(1 - x_1)^{-d(t+1)} \cdots (1 - x_b)^{-d(t+1)}}{(1 - u((1 - x_1)^{-t} - 1)) \cdots (1 - u((1 - x_b)^{-t} - 1))}.$$

Here, $[t^N] f(t) := \frac{f^{(N)}(0)}{N!}$ denotes the coefficient of $t^N$ in the Taylor expansion of a function $f : \mathbb{R} \to \mathbb{R}$ around 0 and

$$\left[ x_1^{N_1} \cdots x_b^{N_b} \right] g(x_1, \ldots, x_b) := \frac{1}{N_1! \cdots N_b!} \left. \frac{\partial^{N_1+\cdots+N_b}}{\partial x_1^{N_1} \cdots \partial x_b^{N_b}} g(0, \ldots, 0) \right|$$

is the coefficient of $x_1^{N_1} \cdots x_b^{N_b}$ in the multidimensional Taylor expansion of a function $g : \mathbb{R}^b \to \mathbb{R}$. Note that $R_d(k, j, b, (n_1, \ldots, n_b)) = 0$ for $k < j$.

**Theorem 3.5** Let $j \in \{0, \ldots, n\}$ and $k \in \{0, \ldots, n\}$ be given. Then, it holds that

$$\sum_{F \in \mathcal{F}_j(K^B)} \nu_k(T_F(K^B)) = \sum_{F \in \mathcal{F}_j(K^A)} \nu_k(T_F(K^A)) = R_1(k, j, b, (n_1, \ldots, n_b)).$$

The proof of Theorem 3.5 is postponed to Sect. 4.2. For finite products of Weyl chambers $W^B := B^{(n_1)} \times \cdots \times B^{(n_b)}$ and $W^A := A^{(n_1)} \times \cdots \times A^{(n_b)}$, we obtain the following theorems.
Theorem 3.6 For \( j \in \{0, \ldots, n\} \) and \( k \in \{0, \ldots, n\} \), it holds that

\[
\sum_{F \in \mathcal{F}_j(W^B)} v_k(T_F(W^B)) = R_{1/2}(k, j, b, (n_1, \ldots, n_b)),
\]

\[
\sum_{F \in \mathcal{F}_j(W^A)} v_k(T_F(W^A)) = R_0(k, j, b, (n_1, \ldots, n_b)).
\]

The proof of Theorem 3.6 is similar to that of Theorem 3.5 and will be omitted. In the proof of Theorem 3.5 we will observe that if we additionally sum over all possible \( n_1, \ldots, n_b \) with fixed sum \( n \), the formulas in terms of Taylor coefficients simplify as follows.

Proposition 3.7 For all \( j \in \{0, \ldots, n\} \) and \( k \in \{0, \ldots, n\} \) we have

\[
\sum_{n_1, \ldots, n_b \in \mathbb{N}_0 \atop n_1 + \cdots + n_b = n} \sum_{F \in \mathcal{F}_j(K^B)} v_k(T_F(K^B)) = \sum_{n_1, \ldots, n_b \in \mathbb{N}_0 \atop n_1 + \cdots + n_b = n} \sum_{F \in \mathcal{F}_j(K^A)} v_k(T_F(K^A))
\]

\[
= \frac{j!}{n!} \binom{j + b - 1}{b - 1} \left[ \frac{n + b}{k + b} \right]_{b/2} \left[ j + b \right]_{b/2}.
\]

The proof is postponed to Sect. 4.3.

3.3 Method of Proof of Theorems 3.1 and 3.3

The main ingredient in proving Theorems 3.1 and 3.3 is the following proposition.

Proposition 3.8 Let \( (j, b) \in \mathbb{N}_0^2 \setminus \{(0, 0)\} \) and \( n \in \mathbb{N} \). For \( l = (l_1, \ldots, l_{j+b}) \) such that \( l_1, \ldots, l_j \in \mathbb{N}, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0, \) and \( l_1 + \cdots + l_{j+b} = n \) we define

\[
T_l := A^{(l_1)} \times \cdots \times A^{(l_j)} \times B^{(l_{j+1})} \times \cdots \times B^{(l_{j+b})}.
\]

Then, for all \( k \in \{0, \ldots, n\} \), we have

\[
\sum_{l_1, \ldots, l_j \in \mathbb{N}, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0 \atop l_1 + \cdots + l_{j+b} = n} v_k(T_l) = \frac{j!}{n!} \left[ \frac{n + b/2}{k + b/2} \right]_{b/2} \left[ j + b/2 \right]_{b/2}.
\]

We will prove this proposition in Sect. 4.1 by computing the generating function of the intrinsic volumes. An alternative proof of Proposition 3.8 can be found in the arXiv version of this paper, see [15, Sect. 4.2]. In order to see that Theorems 3.1 and 3.3 follow from Proposition 3.8, we describe the collections of tangent cones of the Schl"afli orthoschemes and Weyl chambers of types \( A \) and \( B \) at their corresponding faces.
Schläfli Orthoschemes of Type $B$

The faces of $K^B_n$ (and of any polytope in general) are obtained by replacing some of the linear inequalities in its defining conditions by equalities. Thus, each $j$-face of $K^B_n$ is determined by a collection $J := \{i_0, \ldots, i_j\}$ of indices $0 \leq i_0 < i_1 < \cdots < i_j \leq n$ and given by

$$F_J := \{x \in \mathbb{R}^d : 1 = x_1 = \cdots = x_{i_0} \geq x_{i_0+1} = \cdots = x_{i_1} \geq \cdots \geq x_{i_{j-1}+1} = \cdots = x_{i_j} \geq x_{i_{j+1}} = \cdots = x_n = 0\}.$$ 

Note that for $i_0 = 0$, no $x_i$ is required to be 1. Similarly, for $i_j = n$, no $x_i$ is required to be 0. Take a point $x = (x_1, \ldots, x_n) \in \text{relint} F_J$. For this point, all inequalities in the defining condition of $F_J$ are strict. By definition, the tangent cone of $K^B_n$ at $F_J$ is given by

$$T_{F_J}(K^B_n) = \{v \in \mathbb{R}^n : x + \varepsilon v \in K^B_n \text{ for some } \varepsilon > 0\},$$

which is isometric to the product

$$B^{(i_0)} \times A^{(i_1-i_0)} \times \cdots \times A^{(i_j-i_{j-1})} \times B^{(n-i_j)},$$

where the polyhedral cones

$$B^{(i)} := \{x \in \mathbb{R}^i : x_1 \geq \cdots \geq x_i \geq 0\}, \quad A^{(i)} := \{x \in \mathbb{R}^i : x_1 \geq \cdots \geq x_i\},$$

$i \in \mathbb{N}_0$, are the Weyl chambers of type $B$ and $A$, respectively. We arrive at the following lemma.

**Lemma 3.9** The collection of tangent cones $T_F(K^B_n)$, where $F$ runs through the set of all $j$-faces $\mathcal{F}_j(K^B_n)$, coincides (up to isometry) with the collection

$$B^{(i_0)} \times A^{(i_1-i_0)} \times \cdots \times A^{(i_j-i_{j-1})} \times B^{(n-i_j)}, \quad 0 \leq i_0 < i_1 < \cdots < i_j \leq n.$$ 

Equivalently, it coincides (up to isometry) with the collection

$$B^{(l_0)} \times A^{(l_1)} \times \cdots \times A^{(l_j)} \times B^{(l_{j+1})},$$

$l_0 + \cdots + l_{j+1} = n$, $l_0, l_{j+1} \in \mathbb{N}_0$, $l_1, \ldots, l_j \in \mathbb{N}$. 

If the isometry type of some cone appears with some multiplicity in one collection, then it appears with the same multiplicity in the other collections.
Schläfli Orthoschemes of Type $A$

Now, we consider the tangent cones of Schläfli orthoschemes of type $A$. Recall that

$$K_n^A = \{ x \in \mathbb{R}^{n+1} : x_1 \geq \cdots \geq x_{n+1}, \, x_1 - x_{n+1} \leq 1, \, x_1 + \cdots + x_{n+1} = 0 \}.$$  

Note that, unlike in the $B$-case, the simplex $K_n^A$ (which has dimension $n$) is contained in $\mathbb{R}^{n+1}$. For us it will be easier to consider the following unbounded set:

$$\tilde{K}_n^A := \{ x \in \mathbb{R}^{n+1} : x_1 \geq \cdots \geq x_{n+1}, \, x_1 - x_{n+1} \leq 1 \}.$$  

Denote by $L_{n+1}$ the 1-dimensional linear subspace $L_{n+1} = \{ x \in \mathbb{R}^{n+1} : x_1 = \cdots = x_{n+1} \}$. Then $L_{n+1} \perp = \{ x \in \mathbb{R}^{n+1} : x_1 + \cdots + x_{n+1} = 0 \}$ and we have

$$\tilde{K}_n^A = L_{n+1} \oplus K_n^A, \quad K_n^A \subset L_{n+1},$$

where $\oplus$ denotes the orthogonal sum. Thus, there is a one-to-one correspondence $\mathcal{F}_j(K_n^A) \rightarrow \mathcal{F}_j(\tilde{K}_n^A)$ between the $j$-faces of $K_n^A$ and the $(j+1)$-faces of $\tilde{K}_n^A$ given by $F \mapsto L_{n+1} \oplus F$. Furthermore, for every $j$-face $F$ of $K_n^A$ we have a relation between the tangent cones of $K_n^A$ and $\tilde{K}_n^A$ given by

$$T_F \oplus L_{n+1}(\tilde{K}_n^A) = T_F(K_n^A) \oplus L_{n+1}. \quad (3.1)$$

Now, consider the collection of tangent cones $T_F(\tilde{K}_n^A)$, where $F \in \mathcal{F}_j(\tilde{K}_n^A)$ for some $j \in \{1, \ldots, n+1 \}$ and $n \in \mathbb{N}_0$, more closely. The faces of $\tilde{K}_n^A$ are obtained by replacing some inequalities in the defining conditions of $\tilde{K}_n^A$ by equalities. Thus, there are two types of $j$-faces of $\tilde{K}_n^A$ for $j \in \{1, \ldots, n+1 \}$.

The $j$-faces of the first type are of the form

$$F_1 = \{ x \in \mathbb{R}^{n+1} : x_1 = \cdots = x_{i_1} \geq x_{i_1+1} = \cdots = x_{i_2} \geq \cdots \geq x_{i_{j-1}+1} = \cdots = x_{n+1}, \, x_1 - x_{n+1} \leq 1 \} \quad (3.2)$$

for $1 \leq i_1 < \cdots < i_{j-1} \leq n$. Note that for $j = 1$, this reduces to the 1-face $\{ x \in \mathbb{R}^{n+1} : x_1 = \cdots = x_{n+1} \}$. To determine the tangent cone at $F_1$, take some point in the relative interior of this face. For this point, all inequalities in the defining condition of $F_1$ are strict. Call this point $x = (x_1, \ldots, x_{n+1}) \in \text{relint } F_1$. By definition, we have

$$T_{F_1}(\tilde{K}_n^A) = \{ v \in \mathbb{R}^{n+1} : x + \varepsilon v \in \tilde{K}_n^A \text{ for some } \varepsilon > 0 \}.$$  

It follows that

$$T_{F_1}(\tilde{K}_n^A) = \{ v \in \mathbb{R}^{n+1} : v_1 \geq \cdots \geq v_{i_1}, \quad v_{i_1+1} \geq \cdots \geq v_{i_2}, \ldots, v_{i_{j-1}+1} \geq \cdots \geq v_{n+1} \}.$$
Thus, $T_{F_1}(\widetilde{K}_n^A)$ is equal to $A^{(l_1)} \times \cdots \times A^{(l_j)}$, where $l_1, \ldots, l_j \in \mathbb{N}$ satisfy $l_1 + \cdots + l_j = n + 1$ and are given by $l_1 = i_1, l_2 = i_2 - i_1, \ldots, l_j = n + 1 - i_{j-1}$.

The $j$-faces of $\widetilde{K}_n^A$ of the second type are of the form

$$F_2 = \left\{ x \in \mathbb{R}^{n+1} : x_1 = \cdots = x_{i_1} \geq x_{i_1+1} = \cdots = x_{i_2} \geq \cdots \geq x_{i_j+1} = \cdots = x_{n+1}, x_1 - x_{n+1} = 1 \right\}$$

(3.3)

for $1 \leq i_1 < \cdots < i_j \leq n$. The defining condition consists of $j + 1$ groups of equalities and the additional condition $x_1 - x_{n+1} = 1$. Again, take a point $x \in \text{relint } F_2$. For this point all inequalities in the defining condition of $F_2$ are strict. Hence, the tangent cone is given by

$$T_{F_2}(\widetilde{K}_n^A) = \left\{ v \in \mathbb{R}^{n+1} : x + \varepsilon v \in \widetilde{K}_n^A \text{ for some } \varepsilon > 0 \right\}$$

$$= \left\{ v \in \mathbb{R}^{n+1} : v_1 \geq \cdots \geq v_{i_1}, v_{i_1+1} \geq \cdots \geq v_{i_2}, \ldots, v_{i_j+1} \geq \cdots \geq v_{n+1}, v_1 \leq v_{n+1} \right\}$$

$$= \left\{ v \in \mathbb{R}^{n+1} : v_{i_1+1} \geq \cdots \geq v_{i_2}, \ldots, v_{i_j+1} \geq \cdots \geq v_j, v_{j+1} \geq \cdots \geq v_{n+1} \geq v_1 \right\},$$

where in the last step we merged two groups of inequalities. Hence, $T_{F_2}(\widetilde{K}_n^A)$ is isometric to $A^{(l_1+1)} \times A^{(l_2)} \times \cdots \times A^{(l_j)}$, where $l_1, \ldots, l_{j+1} \in \mathbb{N}$ are such that $l_1 + \cdots + l_{j+1} = n + 1$, that is they form a composition of $n + 1$ into $j + 1$ parts.

We can combine both types of tangent cones into one type as follows. For a $(j + 1)$-composition $l_1 + \cdots + l_{j+1} = n + 1$, the numbers $k_1 := l_1 + l_{j+1}, k_2 := l_2, \ldots, k_j := l_j$ form a $j$-composition of $n + 1$. This association is not injective since each $j$-composition $k_1 + \cdots + k_j = n + 1$ of $n + 1$ is assigned to $k_1 - 1$ compositions of $n + 1$ into $j + 1$ parts. Indeed, we can represent $k_1$ as $1 + (k_1 - 1), 2 + (k_2 - 2), \ldots, (k_1 - 1) + 1$. Thus, combining both types of tangent cones yields the following lemma.

**Lemma 3.10** The collection of tangent cones $T_F(\widetilde{K}_n^A)$, where $F$ runs through the set of all $j$-faces $F_j(\widetilde{K}_n^A)$, coincides (up to isometry) with the collection of cones

$$A^{(l_1)} \times \cdots \times A^{(l_j)}, \quad l_1, \ldots, l_j \in \mathbb{N}, \quad l_1 + \cdots + l_j = n + 1,$$

where each cone of the above collection is repeated $l_1$ times (or taken with multiplicity $l_1$).

Then, Theorem 3.1 can be deduced from Proposition 3.8 and Lemma 3.9 (in the $B$-case), respectively Lemma 3.10 (in the $A$-case), as follows.
**Proof of Theorem 3.1 assuming Proposition 3.8** We start with the $B$-case. For $j \in \{0, \ldots, n\}$ and $k \in \{0, \ldots, n\}$, we have

\[
\sum_{F \in \mathcal{F}_j(K_n^B)} \nu_k(T_F(K_n^B)) = \sum_{l_0, l_{j+1} \in \mathbb{N}_0, l_1, \ldots, l_j \in \mathbb{N}} \nu_k(B^{(l_0)} \times A^{(l_1)} \times \cdots \times A^{(l_j)} \times B^{(l_{j+1})})
\]

\[
= \frac{j!}{n!} \left[ \binom{n+1}{k+1} \binom{k+1}{j+1} \right] = \frac{j!}{n!} \left[ \binom{n+1}{k+1} \right] \left[ \binom{k+1}{j+1} \right],
\]

where we used Lemma 3.9 in the first step and Proposition 3.8 with $b = 2$ in the second step.

The $A$-case requires slightly more work. Using the identity $\nu_{k+1}(K_n^A \oplus L_{n+1}) = \nu_k(K_n^A)$ and (3.1), we obtain

\[
\sum_{F \in \mathcal{F}_j(K_n^A)} \nu_k(K_n^A) = \sum_{F \in \mathcal{F}_j(K_n^A)} \nu_{k+1}(T_F(K_n^A) \oplus L_{n+1})
\]

\[
= \sum_{F \in \mathcal{F}_j(K_n^A)} \nu_{k+1}(T_F \oplus L_{n+1}(\tilde{K}_n^A)) = \sum_{F \in \mathcal{F}_{j+1}(\tilde{K}_n^A)} \nu_{k+1}(T_F(\tilde{K}_n^A)).
\]

Applying Lemma 3.10 $j + 1$ times with multiplicity $l_1$ replaced by $l_1, \ldots, l_{j+1}$, we can observe that the collection of tangent cones $T_F(\tilde{K}_n^A)$, where $F$ runs through all $(j+1)$-faces of $\mathcal{F}_{j+1}(\tilde{K}_n^A)$ and each cone of this collection is repeated $j + 1$ times, coincides (up to isometry) with the collection of cones

\[
A^{(l_1)} \times \cdots \times A^{(l_{j+1})}, \quad l_1, \ldots, l_{j+1} \in \mathbb{N}, \quad l_1 + \cdots + l_{j+1} = n + 1,
\]

where each cone is taken with multiplicity $l_1 + \cdots + l_{j+1} = n + 1$. Therefore, we arrive at

\[
\sum_{F \in \mathcal{F}_{j+1}(\tilde{K}_n^A)} (j + 1) \nu_{k+1}(T_F(\tilde{K}_n^A)) = \sum_{l_1, \ldots, l_{j+1} \in \mathbb{N}} (n + 1) \nu_{k+1}(A^{(l_1)} \times \cdots \times A^{(l_{j+1})})
\]

\[
= (n + 1) \frac{(j + 1)!}{(n + 1)!} \left[ \binom{n+1}{k+1} \right] \left[ \binom{k+1}{j+1} \right] = \frac{(j + 1)!}{n!} \left[ \binom{n+1}{k+1} \right] \left[ \binom{k+1}{j+1} \right],
\]

where we used Proposition 3.8. Dividing both sides by $j + 1$ yields the claim. \hfill \Box

**Weyl Chambers of Type B**

For $n \in \mathbb{N}$ recall that

\[
B^{(n)} := \{ x \in \mathbb{R}^n : x_1 \geq x_2 \geq \cdots \geq x_n \geq 0 \}
\]

and $B^{(0)} := \{0\}$ by convention. Now, let $j \in \{0, \ldots, n\}$. Each $j$-face of $B^{(n)}$ is determined by a collection $J := \{i_1, \ldots, i_j\}$ of indices $1 \leq i_1 < \cdots < i_j \leq n$, and
given by

\[ F_J := \{ x \in \mathbb{R}^n : x_1 = \cdots = x_{i_1} \geq \cdots \geq x_{i_{j-1}+1} = \cdots = x_n = 0 \}. \]

Note that for \( i_j = n \), no \( x_i \)'s are required to be 0, and for \( j = 0 \), we obtain the 0-dimensional face \( \{0\} \). In order to determine the tangent cone \( T_{F_J}(B^{(n)}) \) take a point \( x = (x_1, \ldots, x_n) \in \text{relint } F_J \). Again, this point satisfies the defining conditions of \( F_J \) with inequalities replaced by strict inequalities. Thus, the tangent cone is given by

\[ T_{F_J}(B^{(n)}) = \{ v \in \mathbb{R}^n : x + \varepsilon v \in B^{(n)} \text{ for some } \varepsilon > 0 \} \]
\[ = \{ v \in \mathbb{R}^n : v_1 \geq \cdots \geq v_{i_1}, \ldots, v_{i_{j-1}+1} \geq \cdots \geq v_{i_j}, v_{i_{j+1}} \geq \cdots \geq v_n \geq 0 \} \]
\[ = A^{(i_1)} \times A^{(i_2-i_1)} \times \cdots \times A^{(i_{j-1}-i_j)} \times B^{(n-i_j)}. \]

The above reasoning yields the following lemma.

**Lemma 3.11** The collection of tangent cones \( T_F(B^{(n)}) \), where \( F \) runs through the set of all \( j \)-faces \( F_j(B^{(n)}) \), coincides with the collection of polyhedral cones

\[ A^{(l_1)} \times \cdots \times A^{(l_j)} \times B^{(l_{j+1})}, \quad l_1 + \cdots + l_{j+1} = n, \quad l_1, \ldots, l_j \in \mathbb{N}, \quad l_{j+1} \in \mathbb{N}_0. \]

**Weyl Chambers of Type A**

For \( n \in \mathbb{N} \) recall that

\[ A^{(n)} := \{ x \in \mathbb{R}^n : x_1 \geq x_2 \geq \cdots \geq x_n \}. \]

For \( j \in \{1, \ldots, n\} \) every \( j \)-face of \( A^{(n)} \) is determined by a collection \( J := \{i_1, \ldots, i_{j-1}\} \) of indices \( 1 \leq i_1 < \cdots < i_{j-1} \leq n-1 \), and given by

\[ F_J := \{ x \in \mathbb{R}^n : x_1 = \cdots = x_{i_1} \geq \cdots \geq x_{i_{j-1}+1} = \cdots = x_n \}. \]

Note that for \( j = 1 \), we obtain the 1-face \( \{ x \in \mathbb{R}^n : x_1 = \cdots = x_n \} \). In order to determine the tangent cone \( T_{F_J}(A^{(n)}) \) consider a point \( x = (x_1, \ldots, x_n) \in \text{relint } F_J \). In a fashion similar to the case of a \( B \)-type Weyl chamber, we can characterize the tangent cone of \( A^{(n)} \) at \( F_J \) as follows:

\[ T_{F_J}(A^{(n)}) = \{ v \in \mathbb{R}^n : x + \varepsilon v \in A^{(n)} \text{ for some } \varepsilon > 0 \} \]
\[ = \{ v \in \mathbb{R}^n : v_1 \geq \cdots \geq v_{i_1}, \ldots, v_{i_{j-1}+1} \geq \cdots \geq v_n \} \]
\[ = A^{(i_1)} \times A^{(i_2-i_1)} \times \cdots \times A^{(n-i_{j-1})}. \]

This yields the following analogue of Lemma 3.11.
Lemma 3.12 The collection of tangent cones $T_F(A^{(n)})$, where $F$ runs through the set of all $j$-faces $F_j(A^{(n)})$, coincides with the collection of polyhedral cones

$$A^{(l_1)} \times \cdots \times A^{(l_j)}, \quad l_1 + \cdots + l_j = n, \quad l_1, \ldots, l_j \in \mathbb{N}.$$ 

Proof of Theorem 3.3 assuming Proposition 3.8 We start with the $B$-case. For $j \in \{0, \ldots, n\}$ and $k \in \{0, \ldots, n\}$, we have

$$\sum_{F \in F_j(B^{(n)})} \mu_k(T_F(B^{(n)})) = \sum_{l_1, \ldots, l_j \in \mathbb{N}, l_1 + \cdots + l_j = n} \mu_k(A^{(l_1)} \times \cdots \times A^{(l_j)} \times B^{(l_{j+1})})$$

$$= \frac{j!}{n!} \left[ n + \frac{1}{2} \right]_{1/2} \left[ k + \frac{1}{2} \right]_{1/2} = \frac{j!}{n!} 2^{j-n} B[n, k] B[n, k],$$

where we used Lemma 3.11 in the first step, Proposition 3.8 with $b = 1$ in the second step, and the formulas in (2.23) in the last step.

In the $A$-case, for $j \in \{1, \ldots, n\}$ and $k \in \{1, \ldots, n\}$, we have

$$\sum_{F \in F_j(A^{(n)})} \mu_k(T_F(A^{(n)})) = \sum_{l_1, \ldots, l_j \in \mathbb{N}, l_1 + \cdots + l_j = n} \mu_k(A^{(l_1)} \times \cdots \times A^{(l_j)})$$

$$= \frac{j!}{n!} \left[ n \right]_0 \left[ k \right]_0 = \frac{j!}{n!} \left[ n \right]_j \left[ k \right]_j,$$

where we used Lemma 3.12 in the first step and Proposition 3.8 with $b = 0$ in the second step. For $j = 0$ or $k = 0$ the formula is evidently true as well. □

Identities for the Generalized Stirling Numbers

Let us also mention that Proposition 3.8, combined with (2.2) and (2.3), yields the following identities for the generalized Stirling numbers. The full proof can be found in the arxiv version of this paper, see [15].

Corollary 3.13 For $n \in \mathbb{N}$, $j \in \{0, \ldots, n\}$, and $2b \in \mathbb{N}_0$, the following identities hold:

$$\sum_{k=0}^n \binom{n+b}{k+b} \binom{k+b}{j+b} = \frac{n!}{j!} \left( n + 2b - 1 \right) = \frac{n!}{j!} \left( n + 2b - 1 \right), \quad (3.4)$$

$$\sum_{k=0}^n (-1)^k \binom{n+b}{k+b} \binom{k+b}{j+b} = 0. \quad (3.5)$$

Note that (3.5) is a special case of the orthogonality relation between the $r$-Stirling numbers proven by Broder [8, Thm. 25]. Relation (3.4) is also known for $b = 0, 1$, the numbers on the right-hand side being the Lah numbers.
3.4 Expected Face Numbers: Convex Hulls of Gaussian Random Walks and Bridges

The above theorems on the angle sums of the tangent cones of Schläfli orthoschemes yield results on the expected number of faces of Gaussian random walks and random bridges, and their Minkowski sums. Consider independent $d$-dimensional standard Gaussian random vectors

$$X_1^{(1)}, X_2^{(1)}, \ldots, X_{n_1}^{(1)}, X_1^{(2)}, X_2^{(2)}, \ldots, X_{n_2}^{(2)}, \ldots, X_1^{(b)}, X_2^{(b)}, \ldots, X_{n_b}^{(b)}$$

and let $n_1 + \cdots + n_b = n \geq d$. For every $i \in \{1, \ldots, b\}$ we define a random walk $(S_0^{(i)}, S_1^{(i)}, \ldots, S_{n_i}^{(i)})$ by

$$S_k^{(i)} = X_1^{(i)} + \cdots + X_k^{(i)}, \quad k = 1, \ldots, n_i, \quad S_0^{(i)} := 0.$$  

Consider the convex hulls of these random walks:

$$C_{n_1}^{(i)} := \text{conv} \{S_0^{(i)}, S_1^{(i)}, \ldots, S_{n_i}^{(i)}\}, \quad i = 1, \ldots, b.$$  

The following theorem gives a formula for the expected number of $j$-faces of the Minkowski sum of $b$ such convex hulls defined by

$$C_{n_1}^{(1)} + \cdots + C_{n_b}^{(b)} = \{v_1 + \cdots + v_b : v_1 \in C_{n_1}^{(1)}, \ldots, v_b \in C_{n_b}^{(b)}\}.$$  

**Theorem 3.14** Let $0 \leq j < d \leq n$ be given and define $C_{n_1}^{(1)}, \ldots, C_{n_b}^{(b)}$ as above. Then we have

$$\mathbb{E} f_j(C_{n_1}^{(1)} + \cdots + C_{n_b}^{(b)}) = 2 \sum_{l \geq 1} R_1(d - 2l + 1, j, b, (n_1, \ldots, n_b)),$$

where we recall that

$$R_1(k, j, b, (n_1, \ldots, n_b))$$

$$:= [t^k][x_1^{n_1} \cdots x_b^{n_b}] [u^j] \frac{(1 - x_1)^{-(t+1)} \cdots (1 - x_b)^{-(t+1)}}{(1 - u((1-x_1)^{-t} - 1)) \cdots (1 - u((1-x_b)^{-t} - 1))}.$$

The same formula holds for the Minkowski sum of Gaussian random bridges which are essentially Gaussian random walks under the condition that they return to 0 in the last step. To state it, consider independent $d$-dimensional standard Gaussian random vectors

$$X_1^{(1)}, X_2^{(1)}, \ldots, X_{n_1+1}^{(1)}, X_1^{(2)}, X_2^{(2)}, \ldots, X_{n_2+1}^{(2)}, \ldots, X_1^{(b)}, X_2^{(b)}, \ldots, X_{n_b+1}^{(b)}.$$
and define the random walks \((S^{(i)}_0, S^{(i)}_1, \ldots, S^{(i)}_{n_i+1})\) as above. We define the Gaussian bridge \((\tilde{S}^{(i)}_0, \tilde{S}^{(i)}_1, \ldots, \tilde{S}^{(i)}_{n_i+1})\) as a process having the same distribution as the Gaussian random walk \((S^{(i)}_0, S^{(i)}_1, \ldots, S^{(i)}_{n_i+1})\) conditioned on the event that \(S^{(i)}_{n_i+1} = 0\). Equivalently, the Gaussian bridge \((\tilde{S}^{(i)}_0, \tilde{S}^{(i)}_1, \ldots, \tilde{S}^{(i)}_{n_i+1})\) can be constructed as

\[
\tilde{S}^{(i)}_k := S^{(i)}_k - \frac{k}{n_i + 1} S^{(i)}_{n_i+1}, \quad k = 1, \ldots, n_i + 1,
\]

for \(i = 1, \ldots, b\). Note that \(\tilde{S}^{(i)}_{n_i+1} = 0\). Define the convex hulls of the Gaussian bridges by

\[
\tilde{C}^{(i)}_{n_i} := \text{conv}\{\tilde{S}^{(i)}_0, \tilde{S}^{(i)}_1, \ldots, \tilde{S}^{(i)}_{n_i}\}, \quad i = 1, \ldots, b.
\]

**Theorem 3.15** Let \(0 \leq j < d \leq n\) be given and \(\tilde{C}^{(1)}_{n_1}, \ldots, \tilde{C}^{(a)}_{n_b}\) be as above. Then, we have

\[
\mathbb{E} f_j(\tilde{C}^{(1)}_{n_1} + \cdots + \tilde{C}^{(b)}_{n_b}) = 2 \sum_{l \geq 1} R_1(d - 2l + 1, j, b, (n_1, \ldots, n_b)).
\]

For a single convex hull \((b = 1)\), the expected number of \(j\)-faces of \(C^{(1)}_n\) and \(\tilde{C}^{(1)}_n\) is already known (in a more general case), see [19, Thms. 1.2 and 5.1], and given by

\[
\mathbb{E} f_j(C^{(1)}_n) = \mathbb{E} f_j(\tilde{C}^{(1)}_n) = \frac{2 \cdot j!}{n!} \sum_{l=0}^{\infty} \left[ \begin{array}{c} n + 1 \\ d - 2l \end{array} \right] \left[ \begin{array}{c} d - 2l \\ j + 1 \end{array} \right].
\]

This formula is a special case of Theorems 3.14 and 3.15 with \(b = 1\) and \(n_1\) replaced by \(n\).

**3.5 Method of Proof of Theorems 3.14 and 3.15**

The main ingredient in the proof of the named theorems is the following lemma which is due to Affentranger and Schneider [1, (5)].

**Lemma 3.16** Let \(P \subset \mathbb{R}^n\) be a convex polytope with non-empty interior and \(G \in \mathbb{R}^{d \times n}\) be a Gaussian random matrix, that is, its entries are independent and standard normal random variables. Then, for all \(0 \leq j < d \leq n\) we have

\[
\mathbb{E} f_j(GP) = f_j(P) - \sum_{F \in F_j(P)} \gamma_d(T_F(P)),
\]

where the Grassmann angles \(\gamma_d\) were defined in (2.7).
In fact, Affentranger and Schneider [1] proved this formula for a random orthogonal projection of \( P \), while the fact that Gaussian matrices yield the same result follows from a result of Baryshnikov and Vitale [7]. Due to the relation between Grassmann angles and conic intrinsic volumes stated in (2.8), the lemma can be written as

\[
\mathbb{E} f_j(GP) = f_j(P) - 2 \sum_{F \in F_j(P)} \sum_{l=0}^{\infty} \nu_{d+2l+1}(T_F(P)).
\]

Using (2.4), it also follows that under the conditions of Lemma 3.16 we have

\[
\mathbb{E} f_j(GP) = 2 \sum_{F \in F_j(P)} (\nu_{d-1}(T_F(P)) + \nu_{d-3}(T_F(P)) + \cdots).
\] (3.6)

Now take a Gaussian matrix \( G_B = (\xi_{i,j}) \in \mathbb{R}^{d \times n} \), where \( \xi_{i,j}, i \in \{1, \ldots, d\}, j \in \{1, \ldots, n\} \), are independent standard Gaussian random variables. Then, we claim that \( G_B K^B \) has the same distribution as the Minkowski sum \( \widehat{C}_n^{(1)} + \cdots + \widehat{C}_n^{(b)} \). Similarly, for a Gaussian matrix \( G_A \in \mathbb{R}^{d \times (n+b)} \), we claim that \( G_A K^A \) has the same distribution as \( \widehat{C}_n^{(1)} + \cdots + \widehat{C}_n^{(b)} \).

In order to see this, consider the case of a single Schläfli orthoscheme \( K^B_{n_1} \) first. Let \( G_B^{(1)} = (\xi_{i,j}) \in \mathbb{R}^{d \times n_1} \) be a Gaussian matrix. We know that the Schläfli orthoscheme \( K^B_{n_1} \) is the simplex given as the convex hull of the \( n_1 \)-dimensional vectors

\[(0, 0, 0, \ldots, 0), (1, 0, 0, \ldots, 0), (1, 1, 0, \ldots, 0), \ldots, (1, 1, 1, \ldots, 1).\]

Thus, we obtain

\[
G_B^{(1)} K^B_{n_1} = \text{conv}\{ G_B^{(1)} (0, 0, 0, 0) \top, G_B^{(1)} (1, 0, 0, 0) \top, \ldots, G_B^{(1)} (1, 1, 1, 1) \top \}
\]

\[
= \text{conv} \left\{ \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix}, \begin{pmatrix} \xi_{1,1} \\ \vdots \\ \xi_{d,1} \end{pmatrix}, \begin{pmatrix} \xi_{1,1} + \xi_{1,2} \\ \vdots \\ \xi_{d,1} + \xi_{d,2} \end{pmatrix}, \ldots, \begin{pmatrix} \xi_{1,n_1} + \cdots + \xi_{1,1} \\ \vdots \\ \xi_{d,n_1} + \cdots + \xi_{d,1} \end{pmatrix} \right\}
\]

\[
\overset{d}{=} \text{conv} \left\{ S_0^{(1)}, S_1^{(1)}, \ldots, S_{n_1}^{(1)} \right\} = C_{n_1}^{(1)},
\]

where \( \overset{d}{=} \) denotes the distributional equality of two random elements.

Similarly, we consider a Gaussian matrix \( G_A^{(1)} \in \mathbb{R}^{d \times (n+1)} \) for the Schläfli orthoscheme \( K^A_{n_1} \). We know that \( K^A_{n_1} \) is the convex hull of the \( (n_1 + 1) \)-dimensional vectors \( P_0 = (0, 0, \ldots, 0) \) and

\[
P_i = (1, 1 \ldots, 1, 0, \ldots, 0) - \frac{i}{n_1 + 1} (1, 1, \ldots, 1), \quad 1 \leq i \leq n_1.
\]
Thus, in the same way we get

\[
G_A^{(1)} K_{n_1}^A = \text{conv} \left\{ G_A^{(1)} P_0, G_A^{(1)} P_1, \ldots, G_A^{(1)} P_{n_1} \right\}
\]

\[
d = \text{conv} \left\{ 0, S_1^{(1)} - \frac{1}{n_1 + 1} S_n^{(1)} , S_2^{(1)} - \frac{2}{n_1 + 1} S_{n_1 + 1}^{(1)} , \ldots, S_{n_1}^{(1)} - \frac{n_1}{n_1 + 1} S_{n_1 + 1}^{(1)} \right\}
\]

The product case follows from the following observation. Let \( G_B \in \mathbb{R}^{d \times n} \) be a Gaussian matrix and \( n_1 + \cdots + n_b = n \). Then, we can represent \( G_B \) as the row of \( b \) independent matrices \( G_B = (G_B^{(1)}, \ldots, G_B^{(b)}) \), where \( G_B^{(i)} \in \mathbb{R}^{d \times n_i} \) is itself a Gaussian matrix for \( i = 1, \ldots, b \). We can represent each vector \( x \in \mathbb{R}^n \) as the column of \( b \) vectors, i.e., \( x = (x^{(1)}, \ldots, x^{(b)})^\top \), where \( x^{(i)} \in \mathbb{R}^{n_i} \) for \( i = 1, \ldots, b \). Then, we easily observe that

\[
G_B x = (G_B^{(1)}, \ldots, G_B^{(b)}) (x^{(1)}, \ldots, x^{(b)})^\top = G_B^{(1)} x^{(1)} + \cdots + G_B^{(b)} x^{(b)}.
\]

It follows that

\[
G_B K_B = (G_B^{(1)}, \ldots, G_B^{(b)}) (K_{n_1}^B \times \cdots \times K_{n_b}^B)
\]

\[
= G_B^{(1)} K_{n_1}^B + \cdots + G_B^{(b)} K_{n_b}^B = C_{n_1}^{(1)} + \cdots + C_{n_b}^{(b)}.
\]

In the same way we obtain for a Gaussian matrix \( G_A \in \mathbb{R}^{d \times (n+b)} \), \( n_1 + \cdots + n_b = n \), that

\[
G_A K_A = d \tilde{C}_{n_1}^{(1)} + \cdots + \tilde{C}_{n_b}^{(b)}.
\]

Now, we can finally prove Theorems 3.14 and 3.15.

**Proof of Theorem 3.14** Let \( 1 \leq j < d \leq n \) and \( G_B \in \mathbb{R}^{d \times n} \) be a Gaussian matrix. As we already observed, \( G_B K_B = d C_{n_1}^{(1)} + \cdots + C_{n_b}^{(b)} \). Thus, (3.6) yields

\[
\mathbb{E} f_j (C_{n_1}^{(1)} + \cdots + C_{n_b}^{(b)}) = \mathbb{E} f_j (G_B K_B)
\]

\[
= 2 \sum_{F \in \mathcal{F}_j(K_B)} \left( \nu_{d-1}(T_F(K_B)) + \nu_{d-3}(T_F(K_B)) + \cdots \right)
\]

\[
= 2 \sum_{l \geq 1} R_1(d - 2l + 1, j, b, (n_1, \ldots, n_b)),
\]

where we used Theorem 3.5 in the last step. \(\square\)
Proof of Theorem 3.15 Let $1 \leq j < d \leq n$ and let $G_A \in \mathbb{R}^{d \times (n+b)}$ be a Gaussian matrix. We have already seen that $G_A K^A \equiv \tilde{C}^{(1)}_{n_1} + \cdots + \tilde{C}^{(b)}_{n_b}$. Although the polytope $K^A \subset \mathbb{R}^{n+b}$ is only $n$-dimensional, we can still apply Lemma 3.16, and therefore also (3.6), to the ambient linear subspace $\text{lin } K^A$ since the Grassmann angles do not depend on the dimension of the ambient linear subspace. Combining this with Theorem 3.5, we obtain

$$
\mathbb{E} f_j (\tilde{C}^{(1)}_{n_1} + \cdots + \tilde{C}^{(b)}_{n_b}) = \mathbb{E} f_j (G_A K^A) = 2 \sum_{F \in \mathcal{F}_j (K^B)} (v_{d-1} (T_F (K^A)) + v_{d-3} (T_F (K^A)) + \cdots )
$$

$$
= 2 \sum_{l \geq 1} R_1 (d - 2l + 1, j, b, (n_1, \ldots, n_b)),
$$

which completes the proof. \qed

3.6 Application to Compressed Sensing

Let us briefly mention an application of Theorems 3.1 and 3.3 to compressed sensing. Donoho and Tanner [11] have considered the following problem. Let $x = (x_1, \ldots, x_n)$ be an unknown signal belonging to some polyhedral set $P \subset \mathbb{R}^n$ and let $G : \mathbb{R}^n \to \mathbb{R}^k$ be a Gaussian matrix, where $k \leq n$. We would like to recover the signal $x$ from its image $y = Gx$. Following Donoho and Tanner [11], we denote the event that such a recovery is uniquely possible by

$$
\text{Unique}(G, x, P): \quad \text{The system } y = Gx' \text{ has a unique solution } x' = x \text{ in } P.
$$

The recovery is uniquely possible if and only if $(x + \ker G) \cap P = \{x\}$. Assume that $x \in \text{relint } F$ for some $j$-face $F \in \mathcal{F}_j (P)$ of $P$. Then, the following equivalence holds:

$$
\text{Unique}(G, x, P) \iff \ker G \cap T_F (P) = \{0\}. \quad (3.7)
$$

Using this observation, Donoho and Tanner [11] computed the probability of unique recovery explicitly in the cases when $P = \mathbb{R}^n_+$ is the non-negative orthant or $P = [0, 1]^n$ is the unit cube. By the way, the equivalence (3.7) was stated by Donoho and Tanner [11, Lems. 2.1 and 5.1] in these special cases, but it easily generalizes to any polyhedral set. We are now going to use Theorems 3.1 and 3.3 to compute the probabilities of unique signal recovery in the case when $P$ is a Weyl chamber or a Schläfli orthoscheme, which corresponds to natural isotonic constraints frequently imposed in statistics.

Weyl Chambers

We consider the following model for a random signal $x$ that belongs to the Weyl chamber $B^{(n)}$ of type $B$. Let $0 < j \leq n$ be given together with $j$ positive numbers
Proof Using the above equivalence (3.7) and the construction of \( F^B(i_1, \ldots, i_j) \) of \( B^{(n)} \) by

\[
F^B(i_1, \ldots, i_j) := \{ x \in \mathbb{R}^n : x_1 = \cdots = x_{i_1} \geq \cdots \geq x_{i_{j-1}+1} = \cdots = x_j \geq x_{i_j+1} = \cdots = x_n = 0 \}
\]

and consider the signal \( x = (x_1, \ldots, x_n) \) given by

\[
x_m = \sum_{l: i_l \geq m} a_l, \quad m = 1, \ldots, n.
\]

Then, by construction, \( F^B(i_1, \ldots, i_j) \) is random and uniformly distributed on \( F^B_j(B^{(n)}) \). Moreover, \( x \) belongs to relint \( F^B(i_1, \ldots, i_j) \).

**Proposition 3.17** Let \( 0 \leq j \leq k \leq n \) and let \( x \in \mathbb{R}^n \) be a random signal constructed as above (where we put \( x = 0 \) if \( j = 0 \)). If \( G: \mathbb{R}^n \to \mathbb{R}^k \) is a Gaussian random matrix, then it holds that

\[
\mathbb{P}[\text{Unique}(G, x, B^{(n)})] = \frac{2^{j+1} j!}{2^n n!} \sum_{i=1,3,5,\ldots} B[n, k - i]B[k - i, j].
\]

**Proof** Using the above equivalence (3.7) and the construction of \( x \), we obtain that

\[
\mathbb{P}[\text{Unique}(G, x, B^{(n)})] = \sum_{1 \leq i_1 < \cdots < i_j \leq n} \mathbb{P}[\ker G \cap T_{F^B(i_1,\ldots,i_j)}(B^{(n)}) = \{0\}].
\]

Since \( \ker G \) is rotationally invariant, and thus a uniformly distributed \((n - k)\)-dimensional linear subspace, we conclude that the probability on the right-hand side coincides with \( 1 - \gamma_k(T_F(B^{(n)})) \), where \( \gamma_k(T_F(B^{(n)})) \) denotes the \( k \)-th Grassmann angle of \( T_F(B^{(n)}) \). Thus, relation (2.8) yields

\[
\mathbb{P}[\text{Unique}(G, x, B^{(n)})] = \sum_{F \in F_j(B^{(n)})} (1 - \gamma_k(T_F(B^{(n)})))
\]

\[
= 2 \sum_{i=1,3,5,\ldots} \sum_{F \in F_j(B^{(n)})} \psi_k(T_F(B^{(n)}))
\]

\[
= \frac{2^{j+1} j!}{2^n n!} \sum_{i=1,3,5,\ldots} B[n, k - i]B[k - i, j],
\]

where the last equality follows from Theorem 3.3. \( \square \)

In the \( A \)-case the construction is analogous. Let \( 0 < j \leq n \) and let \( a_1, \ldots, a_j \) be positive numbers. Select a random and uniform subset \( \{i_1, \ldots, i_{j-1}\} \subseteq \{1, \ldots, n-1\} \)
with $1 \leq i_1 < \cdots < i_{j-1} \leq n - 1$, put $i_j := n$, and define the corresponding $j$-face $F^A(i_1, \ldots, i_{j-1})$ of $A^{(n)}$ by

$$F^A(i_1, \ldots, i_{j-1}) := \{ x \in \mathbb{R}^n : x_1 = \cdots = x_{i_1} \geq \cdots \geq x_{i_{j-1}+1} = \cdots = x_n \},$$

which is uniformly distributed in $F_j(A^{(n)})$. We define the random signal $x = (x_1, \ldots, x_n)$ by $x_m = \sum_{i:i_i \geq m} a_i$ for $m = 1, \ldots, n$. Then, $x$ belongs to the relative interior of $F^A(i_1, \ldots, i_{j-1})$. This yields the following proposition, which is analogous to the $B$-case and can be proven in a similar way.

**Proposition 3.18** Let $0 < j \leq k \leq n$ and $x \in \mathbb{R}^n$ be a random signal constructed as above. If $G : \mathbb{R}^n \to \mathbb{R}^k$ is a Gaussian random matrix, then it holds that

$$\Pr[\text{Unique}(G, x, A^{(n)})] = \frac{2 \cdot j!}{n!} \left(\frac{n-1}{j-1}\right)^{j-1} \sum_{i=1,3,5,\ldots} \left[\frac{n}{k-i}\right] \left\{\frac{k-i}{j}\right\}.$$ 

### Schlafli Orthoschemes

Again, we start with the $B$-case. Let $0 \leq j \leq n$ be given. Take $j+1$ positive numbers $a_0, a_1, \ldots, a_j$ satisfying $a_0 + \cdots + a_j = 1$ and select a random and uniform subset $\{i_0, \ldots, i_j\} \subseteq \{0, \ldots, n\}$ with $0 \leq i_0 < \cdots < i_j \leq n$. Now, define the corresponding $j$-face $S^B(i_0, \ldots, i_j)$ of $K_n^B$ by

$$S^B(i_0, \ldots, i_j) := \{ x \in \mathbb{R}^n : 1 = x_1 = \cdots = x_{i_0} \geq x_{i_0+1} = \cdots = x_{i_1} \geq \cdots \geq x_{i_{j-1}+1} = \cdots = x_{i_j} \geq x_{i_{j+1}} = \cdots = x_n = 0 \}.$$

Consider the signal $x = (x_1, \ldots, x_n)$ given by

$$x_m = \sum_{i:i_i \geq m} a_i, \quad m = 1, \ldots, n.$$

By construction, we have $x \in \text{relint} S^B(i_0, \ldots, i_j)$ and $S^B(i_0, \ldots, i_j)$ is random and uniformly distributed on $F_j(K_n^B)$. Then, the $B$-case of Theorem 3.1 yields the following proposition.

**Proposition 3.19** Let $0 \leq j \leq k \leq n$ and let $x \in \mathbb{R}^n$ be a random signal constructed as above. If $G : \mathbb{R}^n \to \mathbb{R}^k$ is a Gaussian random matrix, then it holds that

$$\Pr[\text{Unique}(G, x, K_n^B)] = \frac{2 \cdot j!}{n!} \left(\frac{n+1}{j+1}\right)^{j+1} \sum_{i=0,2,4,\ldots} \left[\frac{n+1}{k-i}\right] \left\{\frac{k-i}{j+1}\right\}.$$ 

In the $A$-case, recall the definition of the Schlafli orthoscheme of type $A$:

$$K_n^A = \{ x \in \mathbb{R}^{n+1} : x_1 \geq \cdots \geq x_{n+1}, x_1 - x_{n+1} \leq 1, x_1 + \cdots + x_{n+1} = 0 \}.$$
Take $0 \leq j \leq n$ and positive numbers $a_1, \ldots, a_{j+1}$ satisfying $a_1 + \cdots + a_{j+1} = 1$. Also, select a random and uniform subset $\{i_1, \ldots, i_{j+1}\} \subseteq \{1, \ldots, n+1\}$ such that $1 \leq i_1 < \cdots < i_{j+1} \leq n+1$. If $i_{j+1} = n+1$, we define the corresponding $j$-face of $K^A_n$ to be

$$S^A(i_1, \ldots, i_{j+1}) := \{ x \in \mathbb{R}^{n+1} : x_1 = \cdots = x_{i_1} \geq x_{i_1+1} = \cdots = x_{i_2} \geq \cdots \geq x_{i_{j+1}} = x_{n+1}, x_1 - x_{n+1} \leq 1, x_1 + \cdots + x_{n+1} = 0 \}$$

(which corresponds to the type of face described in (3.2)), while for $i_j \leq n$ we define

$$S^A(i_1, \ldots, i_{j+1}) := \{ x \in \mathbb{R}^{n+1} : x_1 = \cdots = x_{i_1} \geq x_{i_1+1} = \cdots = x_{i_2} \geq \cdots \geq x_{i_{j+1}} + 1 = x_{n+1}, x_1 - x_{n+1} = 1, x_1 + \cdots + x_{n+1} = 0 \}$$

(which corresponds to the type of face described in (3.3)). Due to the one-to-one correspondence between the collections of indices $1 \leq i_1 < \cdots < i_{j+1} \leq n+1$ and the $j$-faces of $K^A_n$, the face $S^A(i_1, \ldots, i_{j+1})$ is uniformly distributed on the set $\mathcal{F}_j(K^A_n)$ of all $j$-faces. We consider the random signal $x = (x_1, \ldots, x_{n+1})$ given by

$$x_m = \sum_{l : i_l \geq m} a_l - c, \quad m = 1, \ldots, n+1,$$

where $c$ is chosen to ensure that $x_1 + \cdots + x_{n+1} = 0$. It can be easily checked that the signal $x$ belongs to the relative interior of $S^A(i_1, \ldots, i_j)$. Then, the $A$-case of Theorem 3.1 yields the following proposition.

**Proposition 3.20** Let $0 \leq j \leq k \leq n$ and $x \in \mathbb{R}^{n+1}$ be a random signal constructed as above. If $G : \mathbb{R}^{n+1} \to \mathbb{R}^k$ is a Gaussian random matrix, then it holds that

$$\mathbb{P}[\text{Unique}(G, x, K^A_n)] = \frac{2 \cdot j!}{n!} \left(\frac{n+1}{j+1}\right)^{-1} \sum_{i=0,2,4,\ldots} \left[\frac{n+1}{k-i}\right] \left[\frac{k-i}{j+1}\right].$$

4 Proofs: Angle Sums of Weyl Chambers and Schl"afli Orthoschemes

In this section, we present the proofs of Propositions 3.8, 3.7, and Theorem 3.5. Most of the proofs rely on explicit expressions for the conic intrinsic volumes of the Weyl chambers. Recall that the Weyl chambers $A^{(n)}$ and $B^{(n)}$ are defined by

$$A^{(n)} := \{ x \in \mathbb{R}^n : x_1 \geq x_2 \geq \cdots \geq x_n \},$$

$$B^{(n)} := \{ x \in \mathbb{R}^n : x_1 \geq x_2 \geq \cdots \geq x_n \geq 0 \}.$$
for \( n \in \mathbb{N} \), and we put \( B^{(0)} := \{0\} \). The intrinsic volumes of the Weyl chambers are known explicitly and given by

\[

\nu_k(A^{(n)}) = \binom{n}{k} \frac{1}{n^k}, \quad \nu_k(B^{(n)}) = \frac{B[n, k]}{2^n n!}
\]

for \( k = 0, \ldots, n \); see, e.g., [20, Thm. 4.2] or [14, Thm. 1.1]. The \( B[n, k] \)'s denote the \( B \)-analogues of the Stirling numbers of the first kind as defined in (2.11).

### 4.1 Proof of Proposition 3.8

Let \( (j, b) \in \mathbb{N}_0^2 \setminus \{(0, 0)\} \). Recall that for \( l = (l_1, \ldots, l_{j+b}) \) such that \( l_1, \ldots, l_j \in \mathbb{N}, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0 \), and \( l_1 + \cdots + l_{j+b} = n \), we define

\[

T_l = A^{(l_1)} \times \cdots \times A^{(l_j)} \times B^{(l_{j+1})} \times \cdots \times B^{(l_{j+b})}.
\]

Our goal is to show that for all \( k \in \{0, \ldots, n\} \),

\[

\sum_{l_1, \ldots, l_j \in \mathbb{N}, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0 \atop l_1 + \cdots + l_{j+b} = n} \nu_k(T_l) = \frac{j!}{n!} \binom{n + b/2}{k + b/2} \{ k + b/2 \} \cdot \frac{j + b/2}{b/2} \cdot \binom{n}{j}. \tag{4.3}
\]

**Proof of Proposition 3.8** Let \( (j, b) \in \mathbb{N}_0^2 \setminus \{(0, 0)\} \) and \( k \in \{0, \ldots, n\} \) be given. By the product formula for conic intrinsic volumes (2.5), the generating polynomial of the intrinsic volumes of \( T_l \) can be written as

\[

P(T_l) := \sum_{k=0}^n \nu_k(T_l) t^k = \left( \sum_{m=0}^{l_1} \nu_m(A^{(l_1)}) t^m \right) \cdots \left( \sum_{m=0}^{l_j} \nu_m(A^{(l_j)}) t^m \right) \times \left( \sum_{m=0}^{l_{j+1}} \nu_m(B^{(l_{j+1})}) t^m \right) \cdots \left( \sum_{m=0}^{l_{j+b}} \nu_m(B^{(l_{j+b})}) t^m \right).
\]

We can consider each sum on the right-hand side separately. Using the representations of Stirling numbers of the first kind and their \( B \)-analogues from (2.9) and (2.11), as well as the intrinsic volumes of the Weyl chambers stated in (4.2), we obtain

\[

\sum_{m=0}^i \nu_m(A^{(i)}) t^m = \frac{1}{i!} \sum_{m=0}^i \binom{i}{m} t^m = \frac{t(t + 1) \cdots (t + i - 1)}{i!}, \quad i \in \mathbb{N}, \tag{4.4}
\]
and

\[
\sum_{m=0}^{i} v_m(B^{(i)}) t^m = \frac{1}{2^i i!} \sum_{m=0}^{i} B[i, m] t^m = \frac{(t + 1)(t + 3) \cdots (t + 2i - 1)}{2^i i!}, \quad i \in \mathbb{N}_0.
\]

Note that for \( i = 0 \) we put \( (t + 1)(t + 3) \cdots (t + 2i - 1) := 1 \) by convention, which is consistent with \( v_0(\{0\}) = 1 \). This yields the following formula:

\[
P_{l_j}(t) = \frac{(t + 1)(t + 3) \cdots (t + 2l_{j+1} - 1)}{2^{l_{j+1}} l_{j+1}!} \cdot \left( \frac{(t + 1)(t + 3) \cdots (t + 2l_{j+b} - 1)}{2^{l_{j+b}} l_{j+b}!} \cdot \frac{t^{l_1}}{l_1!} \cdots \frac{t^{l_j}}{l_j!} \right),
\]

where \( t^r := t(t + 1) \cdots (t + r - 1) \), \( r \in \mathbb{N} \), denotes the rising factorial. Thus, the \( k \)-th conic intrinsic volume of \( T_{l_j} \) is the coefficient of \( t^k \) in the above polynomial \( P_{l_j}(t) \). Note that this already implies \( v_k(T_{l_j}) = 0 \) for \( k < j \). Thus, the left-hand side of (4.3) is 0, which coincides with the right-hand side, since for \( k < j \) we have

\[
\left\{ \frac{k + b}{2} \right\}_b/2 = 0.
\]

Therefore, we only need to consider the case \( k \geq j \). Let \( P_{l_1, \ldots, l_j+b}^{(n)}(m) \), where \( m = 0, \ldots, n \), be the coefficients of the polynomial

\[
t^{l_1} \cdots t^{l_j}(t + 1)(t + 3) \cdots (t + 2l_{j+1} - 1) \cdot (t + 1)(t + 3) \cdots (t + 2l_{j+b} - 1) = \sum_{m=j}^{n} P_{l_1, \ldots, l_j+b}^{(n)}(m) t^m.
\]

Using the notation just introduced, we obtain

\[
\sum_{l_1, \ldots, l_j \in \mathbb{N}, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0 \atop l_1 + \cdots + l_{j+b} = n} v_k(T_{l_j}) = \sum_{l_1, \ldots, l_j \in \mathbb{N}, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0 \atop l_1 + \cdots + l_{j+b} = n} \frac{P_{l_1, \ldots, l_j+b}^{(n)}(k)}{l_1! \cdots l_{j+b}! 2^{l_{j+1}+\cdots+l_{j+b}}}.\]
Now, let \([t^N] f(t) := f^{(N)}(0)/N!\) be the coefficient of \(t^N\) in the Taylor expansion of a function \(f\) around 0. Define

\[
C_{n, j, b}(k) := [t^k] \sum_{l_1, \ldots, l_j, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0 \atop l_1 + \cdots + l_{j+b} = n} \frac{(t l_1) \cdots (t l_j)}{l_1! \cdots l_j!} \cdot \frac{(t + 1)(t + 3) \cdots (t + 2l_{j+1} - 1) \cdots 2^{l_{j+1}} l_{j+1}!}{(t + 1)(t + 3) \cdots (t + 2l_{j+b} - 1) \cdots 2^{l_{j+b}} l_{j+b}!}.
\]

Then, we can observe that

\[
C_{n, j, b}(k) = \sum_{l_1, \ldots, l_j, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0 \atop l_1 + \cdots + l_{j+b} = n} \frac{1}{l_1! \cdots l_{j+b}! 2^{l_{j+1}+\cdots+l_{j+b}}} \cdot [t^k] ((t + 1)(t + 3) \cdots (t + 2l_{j+1} - 1) \cdots (t + 1)(t + 3) \cdots (t + 2l_{j+b} - 1) \cdot t^{l_1} \cdots t^{l_j})
\[
= \sum_{l_1, \ldots, l_j, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0 \atop l_1 + \cdots + l_{j+b} = n} \frac{P_{l_1, \ldots, l_{j+b}}(k)}{l_1! \cdots l_{j+b}! 2^{l_{j+1}+\cdots+l_{j+b}}} = \sum_{l_1, \ldots, l_j, l_{j+1}, \ldots, l_{j+b} \in \mathbb{N}_0 \atop l_1 + \cdots + l_{j+b} = n} v_k(T_i).
\]

Thus, to prove the proposition, it suffices to show that for all \((j, b) \in \mathbb{N}_0^2 \setminus \{(0, 0)\}\) and \(k \in \{j, \ldots, n\}\) we have

\[
C_{n, j, b}(k) = j! \left[ \frac{n + b/2}{k + b/2} \right]_{b/2}^{k + b/2} \left( \frac{k + b/2}{j + b/2} \right)_{b/2}.
\]

(4.5)

To this end, we can introduce a new variable \(x\) and write, by expanding the product,

\[
C_{n, j, b}(k) = [t^k][x^n] \left( \sum_{l=0}^{\infty} \frac{(t + 1)(t + 3) \cdots (t + 2l - 1)}{2^l l!} x^l \right)^b \times \left( \sum_{l=1}^{\infty} \frac{t^l}{l!} x^l \right)^j.
\]

Using (2.9) and the exponential generating function in two variables for the Stirling numbers of the first kind stated in (2.12), we obtain

\[
\sum_{l=1}^{\infty} \frac{t^l}{l!} x^l = -1 + \sum_{l=0}^{\infty} \sum_{m=0}^{l} \frac{\binom{l}{m} t^m x^l}{l!} = (1 - x)^{-t} - 1.
\]

(4.6)
From (2.11) and (2.13), we similarly get

\[
\sum_{l=0}^{\infty} \frac{(t+1)(t+3) \cdots (t+2l-1) \chi^l}{2^l l!} = \sum_{l=0}^{\infty} \sum_{m=0}^{l} B[l, m] t^m \left( \frac{x}{2} \right)^l \frac{1}{l!} = (1 - x)^{-(t+1)/2}.
\] (4.7)

Thus, we have

\[
C_{n,j,b}(k) = \left[ t^k \right] \left[ x^n \right] \left( (1 - x)^{-b(t+1)/2}((1 - x)^{-t} - 1)^j \right) = \left[ x^n \right] \left[ t^k \right] \left( e^{-cb(t+1)/2} \left( e^{-ct} - 1 \right)^j \right),
\]

where we set \( c = c(x) = \log(1 - x) \). The exponential generating function of the \( b/2 \)-Stirling numbers stated in (2.18) yields

\[
e^{-cbt/2} \left( e^{-ct} - 1 \right)^j = \sum_{m=j}^{\infty} \binom{m + b/2}{j + b/2} \frac{j!}{m!} (-ct)^m.
\]

It follows that

\[
\left[ t^k \right] \left( e^{-cb(t+1)/2} \left( e^{-ct} - 1 \right)^j \right) = e^{-cb/2} \left[ t^k \right] \left( \sum_{m=j}^{\infty} \binom{m + b/2}{j + b/2} \frac{j!}{m!} (-ct)^m \right) = e^{-cb/2} \left( -c \right)^k \frac{j!}{k!} \binom{k + b/2}{j + b/2} \binom{b/2}{j/2}.
\]

Furthermore, using (2.17) we obtain

\[
\left[ x^n \right] \left( e^{-cb/2} \left( -c \right)^k \right) = \left[ x^n \right] \left( - \log(1 - x) \right)^k \left( 1 - x \right)^{b/2} \left( 1 - x \right)^{b/2} \left( k + b/2 \right) = \left[ x^n \right] \left( \sum_{m=k}^{\infty} \binom{m + b/2}{k + b/2} \frac{k!}{m!} x^m \right) = \frac{k!}{n!} \binom{n + b/2}{k + b/2} \binom{b/2}{j/2}.
\]
Taking all this into consideration, we obtain
\[
C_{n,j,b}(k) = [x^n] [t^k] (e^{-cb(t+1)}/2) (e^{-ct} - 1)^j
= [x^n] \left( e^{-cb/2} (-c)^k \left[ \frac{j!}{k!} \left( \frac{k+b/2}{j+b/2} \right)_{b/2} \right] \right)
= \frac{j!}{k!} \left[ \frac{k+b/2}{j+b/2} \right]_{b/2} [x^n] (e^{-cb/2} (-c)^k)
= \frac{j!}{n!} \left[ \frac{n+b/2}{k+b/2} \right]_{b/2} \left[ \frac{k+b/2}{j+b/2} \right]_{b/2},
\]
which coincides with (4.5) and therefore completes the proof. \(\square\)

### 4.2 Proof of Theorem 3.5

Let \(b \in \mathbb{N}\). Recall that \(K^B = K^{B}_{n_1} \times \cdots \times K^{B}_{n_b}\) and \(K^A = K^{A}_{n_1} \times \cdots \times K^{A}_{n_b}\) for \(n_1, \ldots, n_b \in \mathbb{N}_0\) such that \(n := n_1 + \cdots + n_b\), where
\[
K^B_d = \{ x \in \mathbb{R}^d : 1 \geq x_1 \geq x_2 \geq \cdots \geq x_d \geq 0 \},
K^A_d = \{ x \in \mathbb{R}^{d+1} : x_1 \geq \cdots \geq x_{d+1}, x_1 - x_{d+1} \leq 1, x_1 + \cdots + x_{d+1} = 0 \},
\]
for \(d \in \mathbb{N}\), denote the Schl"afli orthoschemes of types \(B\) and \(A\) in \(\mathbb{R}^d\), respectively \(\mathbb{R}^{d+1}\). For convenience, we set \(K^B_0 = K^A_0 = \{0\}\). We want to show that
\[
\sum_{F \in \mathcal{F}_j(K^B)} v_k(T_F(K^B)) = \sum_{F \in \mathcal{F}_j(K^A)} v_k(T_F(K^A)) = R_1(k, j, b, (n_1, \ldots, n_b))
\]
holds for all \(j \in \{0, \ldots, n\}\) and \(k \in \{0, \ldots, n\}\), where for \(d \in \{0, 1/2, 1\}\) we define
\[
R_d(k, j, b, (n_1, \ldots, n_b)) := [t^k] [x_1^{n_1} \cdots x_b^{n_b}] [u^j] \frac{(1-x_1)^{-d(t+1)} \cdots (1-x_b)^{-d(t+1)}}{(1-u((1-x_1)^{-t} - 1)) \cdots (1-u((1-x_b)^{-t} - 1))}.
\]

**Proof of Theorem 3.5** We divide the proof into three steps. In the first step we describe the tangent cones \(T_F(K^B)\) in terms of products of Weyl chambers. In Step 2, we derive a formula for the generalized angle sums of the \(T_F(K^B)'s\) and show that the derived formula simplifies to the desired constant \(R_1(k, j, b, (n_1, \ldots, n_b))\). In the third step, following the arguments of the \(B\)-case, we write the conic intrinsic volumes of the tangent cones \(T_F(K^A)\) in terms of products of Weyl chambers, counted with certain multiplicity, and show that the formula for the generalized angle sums in the \(B\)-case also holds in the \(A\)-case.

**Step 1.** Let \(j \in \{0, \ldots, n\}\) and \(k \in \{0, \ldots, n\}\) be given. It is easy to check that the constant \(R_d(k, j, b, (n_1, \ldots, n_b))\) vanishes for \(k < j\), so that we need to consider...
the case $k \geq j$ only. For each $j$-face $F$ of $K^B$, there are numbers $j_1, \ldots, j_b \in \mathbb{N}_0$ satisfying $j_1 + \cdots + j_b = j$, such that

$$F = F_1 \times \cdots \times F_b$$

for some $F_1 \in \mathcal{F}_{j_1}(K^B_{n_1}), \ldots, F_b \in \mathcal{F}_{j_b}(K^B_{n_b})$. Thus, the tangent cone of $K^B$ at $F$ is given by the following product formula:

$$T_F(K^B) = T_{F_1}(K^B_{n_1}) \times \cdots \times T_{F_b}(K^B_{n_b}).$$

In order to see this, observe that $\text{relint } F = \text{relint } F_1 \times \cdots \times \text{relint } F_b$. Take $x = (x^{(1)}, \ldots, x^{(b)}) \in \text{relint } F \subset \mathbb{R}^n$, where $x^{(i)} \in \text{relint } F_i \subset \mathbb{R}^{n_i}$ for $i = 1, \ldots, b$. Then, we have

$$T_F(K^B) = \{v \in \mathbb{R}^n : \exists \epsilon > 0 \text{ with } x + \epsilon v \in K^B\}$$

$$= \{v_1 \in \mathbb{R}^{n_1} : \exists \epsilon > 0 \text{ with } x^{(1)} + \epsilon v_1 \in K^B_{n_1}\} \times \cdots \times \{v_b \in \mathbb{R}^{n_b} : \exists \epsilon > 0 \text{ with } x^{(b)} + \epsilon v_b \in K^B_{n_b}\}$$

$$= T_{F_1}(K^B_{n_1}) \times \cdots \times T_{F_b}(K^B_{n_b}).$$

Applying Lemma 3.9 to the individual terms in the product, we observe that the collection

$$T_{F_1}(K^B_{n_1}) \times \cdots \times T_{F_b}(K^B_{n_b}),$$

where $F_1 \in \mathcal{F}_{j_1}(K^B_{n_1}), \ldots, F_b \in \mathcal{F}_{j_b}(K^B_{n_b})$, coincides (up to isometries) with the collection of cones

$$G_i := A^{(i_1)}_1 \times \cdots \times A^{(i_j)}_j \times \cdots \times A^{(i_j)}_{j_1} \times \cdots \times A^{(i_b)}_{j_b} \times B^{(i_0)}_0 \times B^{(i_{j_1+1})}_{i_0} \times \cdots \times B^{(i_b)}_{i_{j_1+1}},$$

where $i_1^{(1)}, \ldots, i_{j_1}^{(1)}, i_1^{(b)}, \ldots, i_{j_b}^{(b)} \in \mathbb{N}$ and $i_0^{(1)}, i_{j_1}^{(1)}, \ldots, i_0^{(b)}, i_{j_b+1}^{(b)} \in \mathbb{N}_0$ are such that

$$i_0^{(1)} + \cdots + i_{j_1+1}^{(1)} = n_1, \ldots, i_0^{(b)} + \cdots + i_{j_b+1}^{(b)} = n_b.$$
This yields

\[
\sum_{F \in \mathcal{F}_j(K^B)} v_k(T_F(K^B)) = \sum_{j_1, \ldots, j_b \in \mathbb{N}_0} \sum_{F_1 \in \mathcal{F}_{j_1}(K_{n_1}^B), \ldots, F_b \in \mathcal{F}_{j_b}(K_{n_b}^B)} v_k(T_{F_1}(K_{n_1}^B) \times \cdots \times T_{F_b}(K_{n_b}^B))
\]

\[
= \sum_{j_1, \ldots, j_b \in \mathbb{N}_0} \sum_{j_1 + \cdots + j_b = j \atop j_0^{(1)} + \cdots + j_1^{(1)} = n_1} \sum_{j_0^{(b)} + \cdots + j_b^{(b)} = n_b} v_k(G_i).
\]

(4.8)

**STEP 2.** Similarly to the proof of Proposition 3.8, we observe that \( v_k(G_i) \) is the coefficient of \( t^k \) in the polynomial

\[
\sum_{\substack{j_1, \ldots, j_b \in \mathbb{N}_0 \atop j_1 + \cdots + j_b = j}} \frac{(t + 1)(t + 3) \cdots (t + 2i_0^{(1)} - 1)}{2^0_i t_0^{(1)}!} \frac{(t + 1)(t + 3) \cdots (t + 2i_1^{(1)} - 1)}{2^1_{j_1 + 1} i_1^{(1)}!} \ldots \frac{(t + 1)(t + 3) \cdots (t + 2i_b^{(b)} - 1)}{2^b_{j_b + 1} i_b^{(b)}!}.
\]

(4.9)

Following the same arguments as in the proof of Proposition 3.8, we obtain that

\[
\sum_{F \in \mathcal{F}_j(K^B)} v_k(T_F(K^B)) = [t^k] \sum_{j_1, \ldots, j_b \in \mathbb{N}_0} \sum_{j_1 + \cdots + j_b = j \atop j_0^{(1)} + \cdots + j_1^{(1)} = n_1} \sum_{j_0^{(b)} + \cdots + j_b^{(b)} = n_b} \text{term in (4.9)}.
\]

We introduce new variables \( x_1, \ldots, x_b \) and expand the product to write the right-hand side as follows:

\[
[t^k] \sum_{j_1, \ldots, j_b \in \mathbb{N}_0} \left( \sum_{l=1}^{\infty} \frac{t^l x_1^l}{l!} \right)^{j_1} \left( \sum_{l=0}^{\infty} \frac{(t + 1)(t + 3) \cdots (t + 2l - 1)}{2^l l!} x_1^l \right)^2 \ldots \left( \sum_{l=1}^{\infty} \frac{t^l x_b^l}{l!} \right)^{j_b} \left( \sum_{l=0}^{\infty} \frac{(t + 1)(t + 3) \cdots (t + 2l - 1)}{2^l l!} x_b^l \right)^2.
\]
Using the formulas (4.6) and (4.7) we arrive at
\[
\sum_{F \in \mathcal{F}_j(K^B)} u_k(T_F(K^B)) = [t^k] \sum_{j_1, \ldots, j_h \in \mathbb{N}_0 \atop j_1 + \cdots + j_h = j} \left( \left[ x^{n_1}_1 \right] (1 - x_1)^{-(t+1)} (1 - x_1)^{-t} - 1 \right) \\
\times \cdots \times \left[ x^{n_h}_b \right] (1 - x_b)^{-(t+1)} (1 - x_b)^{-t} - 1 \right) \\
\times ((1 - x_1)^{-t} - 1)^{j_1} \cdots ((1 - x_b)^{-t} - 1)^{j_h}) \tag{4.6} \]

By introducing a new variable \( u \) and expanding the product again, we arrive at
\[
\sum_{F \in \mathcal{F}_j(K^B)} u_k(T_F(K^B)) = [t^k]\left[ x^{n_1}_1 \cdots x^{n_h}_b \right] [u^j] ((1 - x_1)^{-(t+1)} \cdots (1 - x_b)^{-(t+1)}) \\
\times \left( \sum_{l=0}^{\infty} ((1 - x_1)^{-t} - 1)^l u^l \right) \cdots \left( \sum_{l=0}^{\infty} ((1 - x_b)^{-t} - 1)^l u^l \right) \\
= [t^k]\left[ x^{n_1}_1 \cdots x^{n_h}_b \right] [u^j] ((1 - x_1)^{-(t+1)} \cdots (1 - x_b)^{-(t+1)}) \\
\times \left( 1 - u((1 - x_1)^{-t} - 1) \cdots (1 - u((1 - x_b)^{-t} - 1) \right) \\
= R_1(k, j, b, (n_1, \ldots, n_h)), \tag{4.10} \]

which completes the proof of the \( B \)-case.

**STEP 3.** In the \( A \)-case, instead of considering \( K^A \), we look at \( \tilde{K}^A = \tilde{K}^A_{n_1} \times \cdots \times \tilde{K}^A_{n_b} \) for \( n_1, \ldots, n_b \in \mathbb{N}_0 \) such that \( n := n_1 + \cdots + n_b \), where
\[
\tilde{K}^A_d = \{ x \in \mathbb{R}^{d+1} : x_1 \geq \cdots \geq x_{d+1}, x_1 - x_{d+1} \leq 1 \}, \quad d \in \mathbb{N},
\]
denotes the unbounded polyhedral set related to \( K^A_d \). Note that \( \tilde{K}^A_0 = \mathbb{R} \).

Following the arguments of Step 1, we can write the tangent cones of \( T_F(K^A) \) (and also \( T_F(\tilde{K}^A) \)) as products of tangent cones at their respective faces. Using \( u_k(K^A_n) = u_{k+1}(K^A_n \oplus L_{n+1}) \) and (3.1), we obtain
\[
\sum_{F \in \mathcal{F}_j(K^A)} u_k(T_F(K^A)) \tag{4.11} = \sum_{F_1 \in \mathcal{F}_j(K^A_{n_1}), \ldots, F_h \in \mathcal{F}_j(K^A_{n_h}) \atop j_1 + \cdots + j_h = j} u_k(T_{F_1}(K^A_{n_1}) \times \cdots \times T_{F_h}(K^A_{n_h})) \\
= \sum_{F_1 \in \mathcal{F}_j(K^A_{n_1}), \ldots, F_h \in \mathcal{F}_j(\tilde{K}^A_{n_h}) \atop j_1 + \cdots + j_h = j} u_{k+b}(T_{F_1}(\tilde{K}^A_{n_1}) \times \cdots \times T_{F_h}(\tilde{K}^A_{n_h})).
\]
Applying Lemma 3.10 to each individual tangent cone in the product, we see that the collection of tangent cones $T_{F_1}(\tilde{K}^A_{n_1}) \times \cdots \times T_{F_b}(\tilde{K}^A_{n_b})$, where $F_1 \in \mathcal{F}_{j_1+1}(\tilde{K}^A_{n_1}), \ldots, F_b \in \mathcal{F}_{j_b+1}(\tilde{K}^A_{n_b})$, coincides (up to isometry) with the collection

$$A^{(i_1^{(1)})} \times \cdots \times A^{(i_{j_1+1}^{(1)})} \times \cdots \times A^{(i_1^{(b)})} \times \cdots \times A^{(i_{j_b+1}^{(b)})},$$

where $i_1^{(1)}, \ldots, i_{j_1+1}^{(1)}, \ldots, i_1^{(b)}, \ldots, i_{j_b+1}^{(b)} \in \mathbb{N}$ are such that

$$i_1^{(1)} + \cdots + i_{j_1+1}^{(1)} = n_1 + 1, \ldots, i_1^{(b)} + \cdots + i_{j_b+1}^{(b)} = n_b + 1$$

and each cone of the above collection is taken with multiplicity $i_1^{(1)} \cdot \cdots \cdot i_1^{(b)}$. Thus, the formula in (4.11) can be rewritten as

$$\sum_{j_1, \ldots, j_b \in \mathbb{N}_0}^{j_1 + \cdots + j_b = j} \sum_{i_1^{(1)} + \cdots + i_{j_1+1}^{(1)} = n_1 + 1 \atop i_1^{(b)} + \cdots + i_{j_b+1}^{(b)} = n_b + 1} i_1^{(1)} \cdot \cdots \cdot i_1^{(b)} \cdot \nu_{k+b}(A^{(i_1^{(1)})} \times \cdots \times A^{(i_{j_b+1}^{(b)})}) \quad (4.12)$$

for $k \in \{b, \ldots, n + b\}$ and $j \in \{b, \ldots, n + b\}$. The conic intrinsic volume on the right-hand side of (4.12) is given as the coefficient of $t^{k+b}$ in the following polynomial:

$$\frac{t_1^{(1)}}{i_1^{(1)!}} \cdot \cdots \cdot \frac{t_{j_1+1}^{(1)}}{i_{j_1+1}^{(1)!}} \cdot \frac{t_1^{(b)}}{i_1^{(b)!}} \cdot \cdots \cdot \frac{t_{j_b+1}^{(b)}}{i_{j_b+1}^{(b)!}}.$$

Thus, the term in (4.12) simplifies to

$$[t^{k+b}] \sum_{j_1, \ldots, j_b \in \mathbb{N}_0}^{j_1 + \cdots + j_b = j} \left( \frac{t_1^{(1)}}{i_1^{(1)!}} \cdot \frac{t_2^{(1)}}{i_2^{(1)!}} \cdot \cdots \cdot \frac{t_{j_1+1}^{(1)}}{i_{j_1+1}^{(1)!}} \right) \left( \frac{t_1^{(b)}}{i_1^{(b)!}} \cdot \frac{t_2^{(b)}}{i_2^{(b)!}} \cdot \cdots \cdot \frac{t_{j_b+1}^{(b)}}{i_{j_b+1}^{(b)!}} \right)$$

$$= [t^{k+b}] \sum_{j_1, \ldots, j_b \in \mathbb{N}_0}^{j_1 + \cdots + j_b = j} \left( x_1^{n_1+1} (tx_1(1-x_1)^{-(t+1)} ((1-x_1)^{-t} - 1)^{j_1}) \right) \cdot \cdots \cdot \left( x_b^{n_b+1} (tx_b(1-x_b)^{-(t+1)} ((1-x_b)^{-t} - 1)^{j_b}) \right)$$

$$= [t^k] x_1^{n_1} \cdot \cdots \cdot x_b^{n_b} (1-x_1)^{-(t+1)} \cdot \cdots \cdot (1-x_b)^{-(t+1)}$$

$$\times \sum_{j_1, \ldots, j_b \in \mathbb{N}_0}^{j_1 + \cdots + j_b = j} (((1-x_1)^{-t} - 1)^{j_1} \cdot \cdots \cdot ((1-x_b)^{-t} - 1)^{j_b}),$$
which coincides with (4.10) and therefore completes the proof. Note that we used (4.6) and

\[
\sum_{l=1}^{\infty} \frac{t^l}{(l-1)!} x^l = tx \sum_{l=0}^{\infty} \frac{(t+1)(t+2) \cdots (t+l)}{l!} x^l = tx \sum_{l=0}^{\infty} \binom{-t-1}{l}(-x)^l = tx (1-x)^{-(t+1)},
\]

which follows from the binomial series. \(\square\)

### 4.3 Proof of Proposition 3.7

Our goal is to show that

\[
\sum_{n_1, \ldots, n_b \in \mathbb{N}_0 \atop n_1 + \cdots + n_b = n} \sum_{F \in \mathcal{F}_j(KB)} \nu_k(T_F(KB)) = \sum_{n_1, \ldots, n_b \in \mathbb{N}_0 \atop n_1 + \cdots + n_b = n} \sum_{F \in \mathcal{F}_j(KA)} \nu_k(T_F(KA)) = \frac{j!}{n!} \binom{j+b-1}{b-1} \binom{n+b}{b} \binom{k+b}{j+b}
\]

holds for \(j \in \{0, \ldots, n\}\) and \(k \in \{0, \ldots, n\}\).

**Proof of Proposition 3.7** At first we show the formula for \(K_B\). In (4.8) we saw that

\[
\sum_{F \in \mathcal{F}_j(KB)} \nu_k(T_F(KB)) = \sum_{j_1, \ldots, j_b \in \mathbb{N}_0 \atop j_1 + \cdots + j_b = j} \sum_{i_0^{(0)} + \cdots + i_{j_1+1}^{(1)} = n_1 \atop \vdots \atop i_{j_b}^{(b)} + \cdots + i_{j_b+1}^{(b)} = n_b} \nu_k(G_i)
\]

holds true for all \(j, k \in \{0, \ldots, n\}\), where

\[
G_i = A^{(i_1^{(1)})} \times \cdots \times A^{(i_{j_1}^{(1)})} \times \cdots \times A^{(i_1^{(b)})} \times \cdots \times A^{(i_{j_b}^{(b)})} \times B^{(i_0^{(1)})} \times B^{(i_{j_1+1}^{(1)})} \times \cdots \times B^{(i_0^{(b)})} \times B^{(i_{j_b+1}^{(b)})}.
\]
Note that in the second sum on the right-hand side the indices satisfy $i^{(l)}_0, i^{(l)}_{j_i+1} \in \mathbb{N}_0$ and $i^{(l)}_1, \ldots, i^{(l)}_{j_i} \in \mathbb{N}$ for all $l \in \{1, \ldots, b\}$. Thus, we obtain

$$
\sum_{n_1, \ldots, n_b \in \mathbb{N}_0 \atop n_1 + \cdots + n_b = n} \sum_{F \in \mathcal{F}_j(K^B)} \nu_k(T_F(K^B)) = \sum_{j_1, \ldots, j_b \in \mathbb{N}_0 \atop j_1 + \cdots + j_b = j} \sum_{n_1, \ldots, n_b \in \mathbb{N}_0 \atop n_1 + \cdots + n_b = n} \sum_{i^{(l)}_1, \ldots, i^{(l)}_{j_i+1} \in \mathbb{N}_0 \atop l_1, \ldots, l_j+1 \in \mathbb{N}_0} \nu_k(G_i)
$$

$$
= \sum_{j_1, \ldots, j_b \in \mathbb{N}_0 \atop j_1 + \cdots + j_b = j} \sum_{l_1, \ldots, l_j \in \mathbb{N}_0, l_{j+1}+l_{j+2b} = n} \nu_k\left( A^{(l_1)} \times \cdots \times A^{(l_j)} \times B^{(l_{j+1})} \times \cdots \times B^{(l_{j+2b})} \right).
$$

The last equation follows from simple renumbering. Applying Proposition 3.8 with $b$ replaced by $2b$ yields

$$
\sum_{n_1, \ldots, n_b \in \mathbb{N}_0 \atop n_1 + \cdots + n_b = n} \sum_{F \in \mathcal{F}_j(K^B)} \nu_k(T_F(K^B)) = \sum_{j_1, \ldots, j_b \in \mathbb{N}_0 \atop j_1 + \cdots + j_b = j} \frac{j!}{n!} \binom{n + b}{k + b} \left[ \frac{k + b}{j + b} \right]_b
$$

$$
= \frac{j!}{n!} \left( \binom{j + b - 1}{b - 1} \right) \binom{n + b}{k + b} \left[ \frac{k + b}{j + b} \right]_b,
$$

where we used the well-known fact that the number of compositions of $j$ into $b$ non-negative integers (which may be 0) is given by $\binom{j+b-1}{b-1}$. The formula for $K^A$ follows from

$$
\sum_{F \in \mathcal{F}_j(K^B)} \nu_k(T_F(K^B)) = \sum_{F \in \mathcal{F}_j(K^A)} \nu_k(T_F(K^A)),
$$

which is due to Theorem 3.5. This completes the proof. \qed
