On Distributed Vector Estimation for Power and Bandwidth Constrained Wireless Sensor Networks

Alireza Sani, Student Member, IEEE, Azadeh Vosoughi, Senior Member, IEEE,

Abstract—We consider distributed estimation of a Gaussian vector with a linear observation model in an inhomogeneous wireless sensor network, where a fusion center (FC) reconstructs the unknown vector, using a linear estimator. Sensors employ uniform multi-bit quantizers and binary PSK modulation, and communicate with the FC over orthogonal power- and bandwidth-constrained wireless channels. We study transmit power and quantization rate (measured in bits per sensor) allocation schemes that minimize mean-square error (MSE). In particular, we derive two closed-form upper bounds on the MSE, in terms of the optimization parameters and propose “coupled” and “decoupled” resource allocation schemes that minimize these bounds. We show that the bounds are good approximations of the simulated MSE and the performance of the proposed schemes approaches the clairvoyant centralized estimation when total transmit power or bandwidth is very large. We study how the power and rate allocation are dependent on sensors’ observation qualities and channel gains, as well as total transmit power and bandwidth constraints. Our simulations corroborate our analytical results and illustrate the superior performance of the proposed algorithms.

Index Terms—Distributed estimation, Gaussian vector, upper bounds on MSE, power and rate allocation, ellipsoid method, quantization, linear estimator, linear observation model.

I. INTRODUCTION

Distributed parameter estimation problem for wireless sensor networks (WSNs) has a rich literature in signal processing community. Several researchers study quantization design, assuming that sensors’ observations are sent over bandwidth constrained (otherwise error-free) communication channels, examples are [3], [9]. In particular, [4] designs the optimal quantizers which maximize Bayesian Fisher information, for estimating a random parameter. Assuming identical one-bit quantizers, [8], [9] find the minimum achievable Cramér-Rao lower bound (CRLB) and the optimal quantizers, for estimating a deterministic parameter. The authors in [4], [5] investigate one-bit quantizers for estimating a deterministic parameter, when the FC employs a spatial BLUE for field reconstruction and communication channel model is additive white Gaussian noise (AWGN). A related problem is studied in [11], in which the FC employs a spatial BLUE for field reconstruction and the MSE is compared with a posterior CRLB.

Recent years have also witnessed a growing interest in studying energy efficient distributed parameter estimation for WSNs, examples are [12]–[14]. For estimating a deterministic parameter [12] explores the optimal power allocation scheme which minimizes total transmit power of the network, subject to an MSE constraint, when the FC utilizes BLUE and sensors digitally transmit to the FC over orthogonal AWGN channels. A converse problem is considered in [13], where the authors minimize the MSE, subject to a total transmit power constraint. For a homogeneous WSN, [14] investigates a bit and power allocation scheme that minimizes the MSE, subject to a total transmit power constraint, when communication channels are modeled as binary symmetric channels. We note that [12]–[14] do not include a total bit constraint in their problem formulations. There is a collection of elegant results on energy efficient distributed parameter estimation with analog transmission, also known as Amplify-and-Forward (AF), examples are [15]–[19]. However, the problem formulations in these works naturally cannot have a bandwidth constraint.

Different from the aforementioned works, that consider either transmit power or bandwidth constraint, we consider distributed parameter estimation, subject to both total transmit power and bandwidth constraints. Similar to [4], [5], [7], we choose total number of bits allowed to be transmitted by all sensors to the FC as the measure of total bandwidth. From practical perspectives, having a total transmit power constraint enhances energy efficiency in battery-powered WSNs. Putting a cap on total bandwidth can further improve energy efficiency, since data communication is a major contributor to the network energy consumption. Our new constrained problem formulation allows us to probe the impacts of both constraints on resource allocation and overall estimation accuracy, and enables us to find the best resource allocation (i.e., power and bit) in extreme cases where: (i) we have scarce total transmit power and ample total bandwidth, (ii) we have plentiful total transmit power and scarce total bandwidth. The paper organization follows. Section II introduces our system model and set up our optimization problem. In Section III we derive two closed-form upper bounds, $D_a$ and $D_b$, on the MSE corresponding to the linear estimator at the FC, in terms of the optimization parameters (i.e., transmit power...
and quantization rate per sensor). In Section IV we propose “coupled” resource allocation schemes that minimize these bounds, utilizing the iterative ellipsoid method. This method conducts multi-dimensional search to find the quantization rate vector. In Section V we propose “decoupled” resource allocation schemes, which rely on one-dimensional search to find the quantization rates. Section VI discusses our numerical results. Section VII concludes our work.

II. SYSTEM MODEL AND PROBLEM STATEMENT

We consider a wireless network with $K$ spatially distributed inhomogeneous sensors. Each sensor makes a noisy observation, which depends on an unobservable vector of random parameters $\theta$, processes locally its observation, and transmits a summary of its observation to a fusion center (FC) over erroneous wireless channels. The FC is tasked with estimating a Gaussian vector $\theta$ in the presence of wireless communication channel errors on the MSE. This MSE, due to observation noises and quantization errors, can be expressed in terms of the MSE distortion metric $E\{ (\theta - \hat{\theta})^2 \}$. Our goal is to find the optimal resource allocation scheme, i.e., quantization rate $L_k$ and transmit power $P_k$, $\forall k$, that minimize $D_0$. In other words, we are interested to solve the following optimization problem:

$$
\min_{D_0} D_0\{ \{L_k, P_k\}_{k=1}^K \}
$$

s.t.

$$
\sum_{k=1}^K L_k \leq B_{tot}, \quad \sum_{k=1}^K P_k \leq P_{tot}, \quad L_k \in \mathbb{Z}_+, \quad P_k \in \mathbb{R}_+, \quad \forall k.
$$

III. CHARACTERIZATION OF MSE

We wish to characterize $D_0$ in terms of the quantization parameters $\{L_k, P_k\}_{k=1}^K$. To accomplish this, we take a two-step approach [12]: in the first step, we assume that the quantization levels transmitted by the sensors are received error-free at the FC. Based on the error-free transmission assumption, we characterize the MSE, due to observation noises and quantization errors. In the second step, we take into account the contribution of wireless communication channel errors on the MSE. This approach provides us with an upper bound on $D_0$, which can be expressed in terms of $\{L_k, P_k\}_{k=1}^K$. Define vector $m = [m_1, \ldots, m_K]^T$, including transmitted quantization levels for all sensors, and vector $\hat{m} = [\hat{m}_1, \ldots, \hat{m}_K]^T$, consisting of recovered quantization levels at the FC. Let:

$$
\theta = Gm, \quad G = E\{ \theta m^T \} E\{ mm^T \}^{-1}.
$$

Note that $\hat{\theta}$ is the linear minimum MSE (LMMSE) estimator, had the FC received the transmitted quantization levels error-free [20]. Having $\hat{m}$, the FC employs the same linear operator $\hat{G}$ to obtain the linear estimate $\hat{\theta} = \hat{G}\hat{m}$. To characterize the MSE, we define covariance matrices $D_{01} = E\{ (\hat{\theta} - \theta)^2 \}$ and $D_{02} = E\{ (\theta - \hat{\theta})^2 \}$. One can verify:

$$
D_0 = D_1 + D_2 + 2E\{ (\hat{\theta} - \theta)(\theta - \hat{\theta})^T \}.
$$
or equivalently:
\[ D_0 = D_1 + D_2 + 2\mathbb{E}\{(\hat{\theta} - \theta)^T(\hat{\theta} - \theta)\} \]
where \( D_1 = \text{tr}(D_1) \) and \( D_2 = \text{tr}(D_2) \). Applying Cauchy-Schwarz inequality and using the fact \((x+y)^2 \leq 2(x^2+y^2)\) for \(x, y \geq 0\), we establish an upper bound on \( D_0 \) as the following:
\[ D_0 \leq (\sqrt{D_1} + \sqrt{D_2})^2 \leq 2(D_1 + D_2) = 2D. \quad (4) \]
Note that the upper bound on \( D_0 \) in (4) consists of two terms: the first term \(2D_1\) represents the MSE due to observation noises and quantization errors, whereas the second term \(2D_2\) is the MSE due to communication channel errors. In other words, the contributions of observation noises and quantization errors in the upper bound are decoupled from those of communication channel errors.

Relying on (4), in the remaining of this section we derive two upper bounds on \( D \), denoted as \( D_a \) and \( D_b \), respectively, in sections III-A and III-B in terms of \((L_k, P_k)_{k=1}^K\). While \( D_a \) is a tighter bound than \( D_b \), its minimization demands a higher computational complexity. Leveraging on \( D_a \) and \( D_b \) expressions derived in this section, in sections IV and V, we derive an upper bound on \( D \) in (3).

### A. Characterization of First Bound \( D_a \)
Recall \( D = D_1 + D_2 \) in (4). Below, we first derive \( D_1 \). Deriving an exact expression for \( D_2 \) remains elusive. Hence we derive an upper bound on \( D_2 \), represented as \( D_2^{upb} \). Let \( D_a = D_1 + D_2^{upb} \). Based on (4), we have \( D_0 \leq 2D_a \leq 2D_a \).

**Derivation of \( D_1 \) in \( D_a \):** Since \( \theta \) is the linear MMSE estimator of \( \theta \) given \( m \), \( D_1 \) is the corresponding error covariance matrix. Consequently \( D_1 = \text{tr}(D_1) \) is (20):
\[ D_1 = \text{tr}(C_0 - \mathbb{E}\{\theta m^T\}(\mathbb{E}\{mm^T\})^{-1}\mathbb{E}\{\theta m^T\}^T), \quad (5) \]
where \( \mathbb{E}\{\theta m^T\} \) and \( \mathbb{E}\{mm^T\} \), respectively, are cross-covariance and covariance matrices. To find these matrices, we need to delve into statistics of quantization errors. For sensor \( k \), let the difference between observation \( x_k \) and its quantization level \( m_k \), i.e., \( \epsilon_k = x_k - m_k \) be the corresponding quantization noise. In general, \( \epsilon_k \) are mutually correlated and also are correlated with \( x_k \)'s. However, in (21) it is shown that, when correlated Gaussian random variables are quantized with uniform quantizers of step sizes \( \Delta_k \)'s, quantization noises can be approximated as mutually independent random variables, that are uniformly distributed in the interval \([-\Delta_k, \Delta_k]\), and are also independent of quantizer inputs. In this work, since \( \theta \) and \( \eta_k \)'s in (1) are assumed Gaussian, \( x_k \)'s are correlated Gaussian that are quantized with uniform quantizers of quantization step sizes \( \Delta_k \)'s. Hence, \( \epsilon_k \) are approximated as mutually independent zero mean uniform random variables with variance \( \sigma_{\epsilon_k} = \Delta_k^2/12 \) that are also independent of \( x_k \)'s (and thus independent of \( \theta \) and \( \eta_k \)'s). These imply \( \mathbb{E}\{\theta m_k\} = \mathbb{E}\{\theta (x_k - \epsilon_k)\} = C_\theta a_k \). Therefore:
\[ \mathbb{E}\{\theta m^T\} = C_\theta A = C_{\theta \theta}. \quad (6) \]
Also, it is straightforward to verify:
\[ \mathbb{E}\{mm^T\} = A^TC_\theta A + C_n + Q = C_x + Q. \quad (7) \]
where \( Q = \text{diag}(\sigma_{\epsilon_1}^2, \ldots, \sigma_{\epsilon_K}^2) \). Substituting (6), (7) into (5), (6) yield:
\[ G = C_{\theta \theta}^{-1}(C_x + Q)^{-1}, \quad (8) \]
\[ D_1 = \text{tr}(C_\theta - \text{tr}(C_{\theta \theta}^{-1}(C_x + Q)^{-1}C_{\theta \theta})). \quad (9) \]

**Derivation of \( D_2^{upb} \) in \( D_a \):** Substituting \( \theta = Gm \) and \( \hat{\theta} = G\hat{m} \) in \( D_2 \) we reach \( D_2 = GMCIG^T \), where we define matrix \( M = \mathbb{E}\{m - m^T(m - m)^T\} \). Since communication channel noises are mutually uncorrelated \( \mathbb{E}\{\eta_i\eta_j\} = 0 \) for \( i \neq j \). Hence \( M \) is a diagonal matrix, whose \( k \)-th entry, \( [M]_{kk} = \mathbb{E}\{\epsilon_k^2\} \), depends on the employed modulation scheme, channel gain \( |h_k| \), channel noise variance \( \sigma_{w_k}^2 \), value of \( \gamma_k \), transmit power \( P_k \), and quantization rate \( L_k \). For our system model depicted in Section III-A in which sensors utilize BPSK modulation, we obtain (see Appendix VIII-A):
\[ [M]_{kk} = \frac{4P_k^2\Delta_k^2}{3}\exp(-\frac{\gamma_k P_k}{L_k}), \quad (10) \]
where \( \gamma_k = \frac{|h_k|^2}{\sigma_{w_k}^2} \) is channel to noise ratio (CNR) for sensor \( k \). Since \( M \) and \( D_2 \) are semi-positive definite matrices, i.e., \( M \succeq 0, D_2 \geq 0 \), the bound in (10) can provide us an upper bound on \( D_2 = \text{tr}(D_2) \). Let \( M' = \text{diag}([m_1, \ldots, m_K]) \). Since \( M' - M \succeq 0 \) and \( G'M'G^T \succeq 0 \), we find (22):
\[ D_2 = \text{tr}(GMCIG^T) \leq \text{tr}(G'M'G^T) = D_2^{upb}, \quad (11) \]
Regarding \( D_1 \) and \( D_2^{upb} \) a remark follows.

**Remark 1:** Note \( D_1 \) in (9) only depends on quantization rates \( L_k \)'s, through the variance of quantization noises \( \epsilon_k \)'s in \( Q \). On the other hand, \( D_2^{upb} \) in (11) depends on transmit powers \( P_k \)'s, through \( M' \), as well as \( L_k \)'s through \( M' \) and \( Q \) in \( G \). Hence, we derive the upper bound \( D_a = D_1 + D_2^{upb} \), in terms of the optimization parameters \( \{L_k, P_k\}_k^{K} \).

### B. Characterization of Second Bound \( D_b \)
Recall from Section III-A that \( D_b = D_1 + D_2^{upb} \) where \( D_0 \leq 2D \leq 2D_a \). Note that both \( D_1 \) and \( D_2^{upb} \) involve inversion of matrix \( C_x + Q \), incurring a high computational complexity that grows with \( K \). For large \( K \) such a matrix inversion, required to find the optimal resource allocation (see Section V-A), is burdensome. To curtail computational complexity, in this section we derive upper bounds on \( D_1 \) and \( D_2^{upb} \), represented as \( D_1^{upb} \) and \( D_2^{upb} \), respectively, that do not involve such a matrix inversion. Let \( D_b = D_1^{upb} + D_2^{upb} \). Based on (4), we have \( D_0 \leq 2D \leq 2D_a \leq 2D_b \).

**Derivation of \( D_1^{upb} \) in \( D_b \):** To find an upper bound on \( D_1 \) in (9) we use the following inequality (16):
\[ \text{tr}(E^TF^{-1}E) \geq \frac{(\text{tr}(E^TF))^2}{\text{tr}(E^TEF)}, \quad (12) \]
where \( E \) is arbitrary and \( F \geq 0 \). Recall \( Q \) is a diagonal matrix with non-negative entries, i.e., \( Q \succeq 0 \). Also, \( C_x \succeq 0 \) since it is a covariance matrix. These imply \( Q + C_x \succeq 0 \). Applying (12) to (9) we reach:
\[ D_1 \leq \text{tr}(C_\theta) - \frac{(\text{tr}(C_{\theta \theta}^{-1}C_x))^2}{\text{tr}(C_{\theta \theta}^{-1}(C_x + Q)^{-1}C_{\theta \theta})} = D_1^{upb}. \quad (13) \]
• **Derivation of** \(D_{2}^{upb}\) **in** \(D_{b}\): To find an upper bound on \(D_{2}^{upb}\) in (11), we take the following steps:

\[
D_{2}^{upb} = \sum_{k=1}^{K} \lambda_k(G^T G \mathcal{M}') \leq \sum_{k=1}^{K} \lambda_k(G^T G) \lambda_k(\mathcal{M}')
\]

\[
(\text{c}) \leq \lambda_{\text{max}}(G^T G) \sum_{k=1}^{K} \lambda_k(\mathcal{M}') = \lambda_{\text{max}}(G^T G) \sum_{k=1}^{K} u_k,
\]

where (a) in (14) is obtained using the facts \(\text{tr}(EF) = \text{tr}(FE)\) for arbitrary \(E, F\) with matching sizes and \(\text{tr}(E) = \sum_k \lambda_k(E) = \sum_k |E_{k,k}|\) for a square matrix \(E\) with eigenvalues \(\lambda_k\)'s, (b) is found using Theorem 9 in [23], and (c) is true since \(\lambda_k(G^T G) \leq \lambda_{\text{max}}(G^T G)\) for \(\forall k\). Next, we derive an upper bound on \(\lambda_{\text{max}}(G^T G)\) in (14). Using \(G\) in (8) we find \(G^T G = (C_x + Q)^{-1} C_{\theta \theta}^T (C_x + Q)^{-1}\). Note \((C_x + Q)^{-1}\) and \(C_{\theta \theta}^T\) are symmetric matrices. Therefore:

\[
\lambda_{\text{max}}(G^T G) = \frac{||G^T G||_2}{||C_x + Q||^{-1}_2} = \lambda_{\text{max}}((C_x + Q)^{-1} C_{\theta \theta}^T C_x + Q)^{-1}
\]

\[
(\text{d}) = \frac{1}{\lambda_{\text{min}}(C_x + Q)}^2 \lambda_{\text{max}}(C_{\theta \theta}^T C_x + Q)
\]

\[
(\text{e}) \leq \frac{1}{\lambda_{\text{min}}(C_x + Q)_{k}} \lambda_{\text{max}}(C_{\theta \theta}^T C_x + Q) = \hat{\lambda}.
\]

\(D_{2}^{upb} \leq \hat{\lambda} \sum_{k=1}^{K} u_k = D_{2}^{upb}\). Regarding \(D_{2}^{upb}\) and \(D_{2}^{upb}\) in (13) a remark follows.

• **Remark 2:** Note \(D_{1}^{upb}\) in (13) only depends on \(L_k\)'s, through the variances of quantization noises \(\xi_k\)'s in \(Q\). On the other hand, \(D_{2}^{upb}\) depends on \(P_k\)'s, through \(u_k\)'s, as well as \(L_k\) through \(\xi_k\)'s and \(\sigma_{\xi_k}^2\)'s in \(\lambda\). Hence, we derive the upper bound \(D_b = D_{1}^{upb} + D_{2}^{upb}\), in terms of \(\{L_k, P_k\}_{k=1}^{K}\).

IV. "**Coupled**" SCHEME FOR RESOURCE ALLOCATION

So far, we have established \(D_b \leq 2D \leq 2D_a \leq 2D_b\), where \(D_a\) and \(D_b\) are derived in sections III-A and III-B in terms of \(\{L_k, P_k\}_{k=1}^{K}\). In this section we address the optimization problem formulated in (2), when \(D_a\) is replaced with \(D_b\) (in Section IV-A) or \(D_b\) (in Section IV-C). Note that (2) is a mixed integer nonlinear programming with exorbitant computational complexity [23]. To simplify the problem, we temporarily relax the integer constraint on \(L_k\)'s and allow them to be positive numbers, i.e., we consider:

\[
\text{minimize } D_0\{L_k, P_k\}_{k=1}^{K}, \forall k
\]

\[
\text{s.t. } \sum_{k=1}^{K} L_k \leq B, \sum_{k=1}^{K} P_k \leq P_{\text{tot}}, \forall k \in \mathbb{R}_+, \forall k.
\]

We propose “coupled” scheme to solve the relaxed problem in (16), where the objective function is replaced with \(D_a\) or \(D_b\). In Section IV-B, we discuss a novel approach to migrate from relaxed continuous \(L_k\)'s to integer \(L_k\)'s solutions.

A. Coupled Scheme for Minimizing \(D_a\)

The quintessence of this “coupled” scheme follows. We replace \(D_a\) with \(D_a\) in (16) and decompose the relaxed problem into two sub-problems (SP1) and (SP2) as the following:

\(\text{(SP1)}\) given \(\{L_k\}_{k=1}^{K}, \forall k \in \mathbb{R}_+, \forall k\), minimize \(D_a\{P_k\}_{k=1}^{K}\)

\[
\text{s.t. } \sum_{k=1}^{K} P_k \leq P_{\text{tot}}, P_k \in \mathbb{R}_+, \forall k,
\]

\(\text{(SP2)}\) given \(\{P_k\}_{k=1}^{K}, \forall k \in \mathbb{R}_+, \forall k\), minimize \(D_a\{L_k\}_{k=1}^{K}\)

\[
\text{s.t. } \sum_{k=1}^{K} L_k \leq B, L_k \in \mathbb{R}_+, \forall k.
\]

We iterate between solving these two sub-problems, until we reach the solution.

• **Solving (SP1)** Given in (17): Considering Remark 1, we note that only \(D_{2}^{upb}\) in \(D_{b}\) depends on \(P_k\)'s. Hence, we replace the objective function in (17) with \(D_{2}^{upb}\). Since \(D_{2}^{upb}\) is a jointly convex function of \(P_k\)'s (see Appendix VIII-B) we use Lagrange multiplier method and solve the corresponding Karush-Kuhn-Tucker (KKT) conditions to find the solution. Substituting \(u_k\) of (10) into \(\mathcal{M}'\) and noting that \(G\) does not depend on \(P_k\)'s, we rewrite (SP1) as below:

\[
given\{L_k\}_{k=1}^{K}, \forall k \in \mathbb{R}_+, \forall k, \text{ minimize } \sum_{k=1}^{K} \alpha_k L_k \exp(-\gamma_k P_k/L_k)\]

\[
\text{s.t. } \sum_{k=1}^{K} P_k \leq P_{\text{tot}}, P_k \in \mathbb{R}_+, \forall k,
\]

where \(\alpha_k = (4r^2/3)||g_k||^2 + ||g_k||^2\) is the squared Euclidean norm of the \(k\)-th column of \(G\). Let \(L\{L_k, P_k, \mu_k\}_{k=1}^{K}, \lambda\) be the Lagrangian for (19), where \(\mu_k\) and \(\lambda\) are the Lagrange multipliers. The corresponding KKT conditions are:

\[
\nabla \mathcal{L} = -\alpha_k \gamma_k \exp(-\gamma_k P_k/L_k) - \mu_k + \lambda = 0, \forall k,
\]

\[
P_k \mu_k = 0, \quad \mu_k \geq 0, \quad P_k \geq 0, \forall k,
\]

\[
\lambda \sum_{k=1}^{K} (P_k - P_{\text{tot}}) = 0, \quad \lambda \geq 0, \quad \sum_{k=1}^{K} P_k \leq P_{\text{tot}}.
\]

Since \(D_{2}^{upb}\) is a decreasing function of \(P_k\)'s and \(P_{\text{tot}}\) (see Appendix VIII-B), solving (19) for \(P_k\)'s we find:

\[
P_k = \left[\frac{L_k}{\gamma_k} \ln\left(\frac{\alpha_k}{\lambda}\right)\right]^+, \forall k,
\]

where \([x]^+ = \max(0, x)\), \(\sum_{k=1}^{K} P_k = P_{\text{tot}}\) and \(\ln \lambda^*\) is:

\[
\ln \lambda^* = \left(\sum_{k \in \mathcal{I}} \frac{L_k}{\gamma_k}\right)^{-1} \left[ -P_{\text{tot}} + \sum_{k \notin \mathcal{I}} \frac{L_k}{\gamma_k} \ln(\gamma_k \alpha_k) \right].
\]

Set \(\mathcal{I} = \{k : P_k = 0, k = 0, ..., K\}\) in (21) is the set of inactive sensors: sensors whose \(L_k = 0\) or \(\gamma_k \alpha_k < \lambda^*\), where \(\gamma_k\) is CNR of sensor \(k\) and \(\alpha_k\) depends on the parameters of the observation model. Eq. (20) indicates that \(P_k\) depends on both sensor observation and communication channel qualities, through \(\gamma_k\) and \(\alpha_k\). Also, sensor \(k\) with a larger \(L_k\) is allocated
a larger $P_k$. For asymptotic regime of large $P_{tot}$, we substitute (21) into (20) and let $P_{tot} \to \infty$ to reach the following:

$$P_k = \frac{L_k P_{tot}}{\gamma_k \sum_{k \notin I} L_k \gamma_k}, \quad \forall k.$$  
(22)

Eq. (22) implies in this asymptotic regime, $P_k$ is proportional to $\frac{L_k}{\gamma_k \gamma^*}$. When $L_k$’s are equal, sensor with a smaller $CNR$ is allotted a larger $P_k$ (inverse of water-filling). When $\gamma_k$’s are equal, sensor with a larger $L_k$ is assigned a larger $P_k$. Regarding the solution in (20) two remarks follow.

- **Remark 3**: For sensor $k$, we examine how $P_k$ varies as $\gamma_k$ changes, for a given $L_k$. Obtain:

$$\frac{\partial P_k}{\partial \gamma_k} = \frac{L_k (1 - \ln (\frac{\gamma_k \alpha_k}{\lambda^*}))}{\gamma_k}, \quad \forall k.$$  
(23)

Examining (23) shows when $\gamma_k \alpha_k < e^{\lambda^*}$, as $\gamma_k$ increases $P_k$ increases (water-filling). On the other hand, when $\gamma_k \alpha_k > e^{\lambda^*}$, as $\gamma_k$ increases $P_k$ decreases (inverse of water-filling).

- **Remark 4**: For sensors $i, j$ we examine how $P_i, P_j$ are related to $\gamma_i, \gamma_j$. Suppose $L_i = L_j = L$ and $\alpha_i = \alpha_j = \alpha$. When $\gamma_i \alpha < \gamma_j \alpha$ then $P_i > P_j$ (inverse of water-filling). On the other hand, when $\gamma_i \alpha > \gamma_j \alpha$ then $P_i < P_j$ (water-filling).

- **Solving (SP2)** Given in (18): Finding a closed-form solution for this problem remains elusive, due to non-linearity of the cost function and the fact that the inequality constraint on $L_k$ is not necessarily active. Let $F = \{L_k : \sum_{k=1}^{K} L_k \leq B_{tot}, L_k \in \mathbb{R}_+, \forall k\}$ be the feasible set of (SP2). To solve (SP2) we use a modified version of Ellipsoid method [20]. This cutting-plane optimization method is the generalized form of the one-dimensional bisection method for higher dimensions, and is theoretically efficient with guaranteed convergence [20].

The description of the method follows. Suppose the solution of (SP2) is contained in an initial ellipsoid $E^0$ with center $L^{(0)}$ and shaped by matrix $S^{(0)}$.

The definition of $E^0$ is:

$$E^0 = \{z: (z - L^{(0)})^T S^{(0)^{-1}}(z - L^{(0)}) \leq 1\}.$$

For $E^0$ we choose a sphere that contains $F$, with center $L^{(0)} = \frac{B_{tot}}{2} [1, ..., 1]$, radius $\frac{B_{tot}}{2} \sqrt{K}$, and thus $S^{(0)} = \frac{(B_{tot} \sqrt{K})^2}{2} I_K$. Essentially, this method uses gradient evaluation at iteration $i$, to discard half of $E^0$ and to form $E^{i+1}$ with center $L^{(i+1)}$, which is the minimum volume ellipsoid covering the remaining half of $E^0$. Note that $E^{i+1}$ can be larger than $E^0$ in diameter, however, it is proven that the volume of $E^{i+1}$ is smaller than that of $E^0$ and center $L^{(i)}$ eventually converges to the solution of (SP2). To elaborate this method, suppose at iteration $i$, we have ellipsoid $E^i$ with center $L^{(i)}$ and shaped by matrix $S^{(i)}$. Ellipsoid $E^{i+1}$ at iteration $i+1$ is obtained by evaluating the gradient $\nabla^{(i)}$, defined below. When $L^{(i)} \in F$ then $\nabla^{(i)}$ is the gradient of the objective function (so-called objective cut) evaluated at $L^{(i)}$. When $L^{(i)} \notin F$ then $\nabla^{(i)}$ is the gradient of the inequality constraint that is being violated (so-called feasibility cut) evaluated at $L^{(i)}$. The update steps are:

$$e^{i+1} = e^i \cap \{z: (z - L^{(i)})^T (z - L^{(i)}) \leq 0\},$$

$$L^{(i+1)} = L^{(i)} - \frac{1}{K+1} S^{(i)^{\frac{1}{2}}} \nabla^{(i)} ,$$

$$S^{(i+1)} = \frac{K^2}{K^2 - 1} (S^{(i)} - \frac{2}{K+1} S^{(i)} \nabla^{(i)^T} S^{(i)^{\frac{1}{2}}} \nabla^{(i)}),$$

in which:

$$\nabla^{(i)} = \begin{cases}
\nabla^{(i)}_{oc}, & \text{if } \sum_{k=1}^{K} L_k^{(i)} \leq B_{tot}, L_k^{(i)} \in \mathbb{R}_+, \forall k,

\nabla^{(i)}_{sfc}, & \text{if } \sum_{k=1}^{K} L_k^{(i)} > B_{tot}, L_k^{(i)} \in \mathbb{R}_+, \forall k,

\nabla^{(i)}_{nfc}, & \text{if } L_j^{(i)} \leq 0, \text{ for some } j \in \{1, \ldots, K\},
\end{cases}$$

where $\nabla^{(i)}_{oc}$, $\nabla^{(i)}_{sfc}$ and $\nabla^{(i)}_{nfc}$ are objective cut, rate-sum constraint feasibility cut and nonnegative rate feasibility cut, respectively, evaluated at $L^{(i)}$:

$$\nabla^{(i)}_{oc} = \left[\frac{\partial D_a}{\partial L_1} |_{L_1=\ldots=1^{(i)}}, \ldots, \frac{\partial D_a}{\partial L_K} |_{L_K=\ldots=1^{(i)}}\right]^T,$$

$$\nabla^{(i)}_{sfc} = \left[\frac{\partial (\sum_{j=1}^{K} L_j^{(i)})}{\partial L_1} |_{L_1=\ldots=1^{(i)}}, \ldots, \frac{\partial (\sum_{j=1}^{K} L_j^{(i)})}{\partial L_K} |_{L_K=\ldots=1^{(i)}}\right]^T,$$

$$\nabla^{(i)}_{nfc} = [\frac{\partial L_j^{(i)}}{\partial L_1} |_{L_1=\ldots=1^{(i)}}, \ldots, \frac{\partial L_j^{(i)}}{\partial L_K} |_{L_K=\ldots=1^{(i)}}]^T.$$  
(24)

(25)

(26)

After some mathematical manipulations and using the fact $\frac{\partial x^{-1}}{\partial x} = -x^{-1}\frac{\partial x}{\partial x}$, we find $\frac{\partial x}{\partial x_k} \forall k$ in (24) is equal to:

$$\text{tr}(G^i \frac{\partial Q}{\partial L_k} - \frac{\partial Q}{\partial L_k} (C_x + Q)^{-1} M' + \frac{\partial M'}{\partial L_k} - M' (C_x + Q)^{-1} \frac{\partial Q}{\partial L_k} | G^T),$$

in which $\frac{\partial Q}{\partial L_k}$ and $\frac{\partial M'}{\partial L_k}$ are all-zero matrices, except for one non-zero element in each matrix $[\frac{\partial Q}{\partial L_k}]_{k,k} = \frac{\partial \sigma_k^2}{\partial L_k} = -2 \frac{L_k}{2 K} \frac{\sigma_k^2}{\sum \sigma_i^2 - 1}$ and $[\frac{\partial M'}{\partial L_k}]_{k,k} = \frac{\partial L_k'}{\partial L_k} = -2 \frac{\sigma_k^2}{3 \sum \sigma_i^2} \exp(\frac{-\gamma_k P_{tot}}{\sum \gamma_i})[1 + \frac{\gamma_k P_{tot}}{\sum \gamma_i}]$. Furthermore, $\nabla^{(i)}_{sfc}$ in (25) is a vector of all ones and $\nabla^{(i)}_{nfc}$ in (26) is a vector of all zeros and $-1$ for its $j$-th entry. As stopping criterion, we check if $\nabla^{(i)}_{oc} \nabla^{(i)}_{sfc} \nabla^{(i)}_{nfc} < \varepsilon$, where $\varepsilon$ is a predetermined error threshold, or if the number of iterations exceeds a predetermined maximum $I_{max}$. Fig. 2 illustrates the above ellipsoid method for $K = 2$ sensors, where the feasible set $F$ is the triangle with the hatch pattern.

In nutshell, we have analytically solved (SP1) and provided an iterative ellipsoid method with guaranteed convergence to address (SP2). With these ammendations we tackle the problem in (16), when $D_0$ is replaced with $D_a$. Let vectors $L^c = [L_1^c, \ldots, L_K^c]$, $P^c = [P_1^c, \ldots, P_K^c]$ denote the solutions to (16). We take an iterative approach that switches between solving (SP1) and (SP2), until we converge to vectors $L^c$ and $P^c$. As stopping criterion, we check if the decrease in $D_a$ in two consecutive iterations is less than a predetermined error threshold $\eta$, or if the number of switching between solving (SP1) and (SP2) exceeds a predetermined maximum $I_{max}$. The “a-coupled” algorithm summarizes the steps described above, guaranteeing that $D_a$ decreases in each iteration $j$.

- **Remark 5**: Implementing the ellipsoid method requires a $K$-dimensional search. Also, in inner loop where $L^{(i)} \in F$ we have $\nabla^{(i)} = \nabla^{(i)}_{oc}$, which needs inversion of $C_x + Q$. In outer loop inversion of $C_x + Q$ is required to update $\alpha_k^{(j)}$. 
We describe an approach on how to migrate from continuous solution $L^e$ to integer solution $L^d$. Let $X$ be the index set of sensors which quantization rates are discretized. Initially $X$ is an empty set. We consider two scenarios: (i) $\sum_{j \in X} L_j^d + \sum_{j \notin X} L_j^e < B_{tot}$, (ii) $\sum_{j \in X} L_j^d + \sum_{j \notin X} L_j^e = B_{tot}$. When case (i) occurs, it means that minimizing $D_a$ has not been negatively impacted by bandwidth shortage. Hence, we discritize the rate of sensor $j$ with the smallest $L_j^e$, since this sensor is more likely to be the weakest player in the network, in the sense that it has the minimal contribution to $D_a$. We round $L_j^e$ “up” or “down”, depending on which one yields a smaller $D_a$ and consider the discritized $L_j^d$ as fixed and final value. When case (ii) occurs, it is very likely that minimizing $D_a$ has been negatively impacted by bandwidth shortage and some sensors were imposed smaller rates, compared with an unlimited $B_{tot}$ scenario. Note that in case (ii), rounding up the rate of any sensor, would enforce decreasing the rates of some other sensors. Hence, we should discritize in a way that, the positive impact of rounding up a rate on $D_a$ would dominate the negative effect of decreasing the rates of some other sensors on $D_a$. Therefore, we discritize the rate of sensor $j$ with the largest $L_j^e$, since this sensor is more likely to be the strongest player, in the sense that it has the maximal contribution to $D_a$. We round $L_j^e$ “up” and consider the discritized $L_j^d$ as fixed and final value. After each discritization, we need to update $X$ and the available bandwidth to $B_{tot} - \sum_{j \in X} L_j^d$, and apply “$a$-coupled” algorithm to reallocate $P_{tot}$ among all sensors and $B_{tot} - \sum_{j \in X} L_j^d$ among those sensors with continous valued rates. We continue this procedure until $X$ includes all sensors.

### C. Coupled Scheme for Minimizing $D_b$

Similar to Section IV-A in this section we consider two sub-problems, which we refer to as (SP3) and (SP4). They are similar to (17) and (18), with the difference that $D_a$ is replaced with $D_b$. Solutions to (SP3) and (SP4) follow.

- **Solving (SP3):** Considering Remark 2, we note that only $D_{2}^{upb}$ in $D_b$ depends on $P_k$. Hence, we replace the objective function in (SP3) with $D_{2}^{upb}$. Since $D_{2}^{upb}$ is a jointly convex function of $P_k$’s (see Appendix VIII-B) we use Lagrange multiplier method and solve the corresponding KKT conditions to find the solution. Also, $D_{2}^{upb}$ is a decreasing function of $P_k$’s and $P_{tot}$ (see Appendix VIII-B). Therefore, solving (SP3) for $P_k$’s we find:

$$P_k = \left[ \frac{L_k}{\gamma_k} \ln (\gamma_k r_k^2) \right]^+, \forall k,$$

where $k = 1, \ldots, K, P_k = P_{tot}, (27)$

$$\ln \mu^* = \left( \sum_{k \in J} \frac{L_k}{\gamma_k} \right)^{-1} [-P_{tot} + \sum_{k \in J} \frac{L_k}{\gamma_k} \ln (\gamma_k r_k^2)]. \quad (28)$$

Set $J = \{ k : P_k = 0, k = 1, \ldots, K \}$ in (28) is the set of inactive sensors: sensors whose $L_k = 0$ or $\gamma_k r_k < \mu^*$. It is noteworthy to mention that for asymptotic regime of large $P_{tot}$, we have the same power allocation policy as in (22).

- **Solving (SP4):** We apply the modified ellipsoid method we used for (SP2), to solve (SP4). The feasible set $F$ and the update steps are similar, with a difference: the gradient of the objective function $\nabla_{^2 c}^\circ$ changes and instead of $\frac{\partial D_1}{\partial L_1}, \frac{\partial D_1}{\partial L_1}$
needs to be derived. However, \( \frac{\partial D_{1}^{upb}}{\partial L_{k}} - \frac{\partial D_{2}^{upb}}{\partial L_{k}} + \frac{\partial D_{3}^{upb}}{\partial L_{k}} \), where:

\[
\frac{\partial D_{1}^{upb}}{\partial L_{k}} = -\left( \text{tr}(C_{\theta}^{T}C_{\theta}^{'}) \right)^{2} \frac{\partial \text{tr}(C_{\theta}^{T}Q_{\theta}C_{\theta}^{'})}{\partial L_{k}} \left( \frac{\partial C_{\theta}^{'}}{\partial L_{k}} C_{\theta}^{' \dagger} \right) \frac{\partial C_{\theta}^{T}}{\partial L_{k}} C_{\theta},
\]

\[
\frac{\partial D_{2}^{upb}}{\partial L_{k}} = \left\{ \begin{array}{ll}
\tilde{\lambda} \frac{\partial u_{k}}{\partial L_{k}}, & \text{if } k \notin A, \\
\tilde{\lambda} \left( \frac{\partial u_{k}}{\partial L_{k}} - \frac{\partial \sigma_{k}^{2}}{\partial L_{k}} \sum_{i=1}^{K} u_{ki} \right), & \text{if } k \in A,
\end{array} \right.
\]

in which set \( A = \{ k : k = \arg \min \sigma_{k}^{2} \} \), \( \tilde{\lambda} \) is defined in (15) and \( \partial u_{k}/\partial L_{k}, \partial \sigma_{k}^{2}/\partial L_{k} \) are given in Section IV-A. Having the solutions for (SP3) and (SP4), we can address the problem in (16), where \( D_{0} \) is replaced with \( D_{b} \), utilizing an iterative algorithm similar to “a-coupled” algorithm outlined in Section IV-A which we call “b-coupled” algorithm, and a discretizing approach similar to Section IV-B. Different from “a-coupled” algorithm, “b-coupled” algorithm does not require matrix inversion, although implementing the modified ellipsoid method still requires a \( K \)-dimensional search.

V. “DECOUPLED” SCHEME FOR RESOURCE ALLOCATION

In Section IV we proposed two iterative coupled schemes, which minimize \( D_{a} \) and \( D_{b} \). In both schemes we resorted to the iterative modified ellipsoid method to find \( L_{k} \)’s, since finding a closed-form solution for \( L_{k} \)’s remained elusive. We recall the discussion at the beginning of Section III which indicates \( D_{1} \) (and its bound \( D_{1}^{upb} \)) represent the MSE due to observation noises and quantization errors, whereas \( D_{2} \) (and its bounds \( D_{2}^{upb}, D_{2}^{opt} \)) are the MSE due to communication channel errors. Leveraging on this decoupling of the contributions of observation noises and quantization errors from those of communication channel errors, we propose “decoupled” scheme to minimize these decoupled contributions separately, and to find the optimization parameters \( \{ L_{k}, P_{k} \}_{k=1}^{K} \) in closed-form expressions, eliminating the computational burden of the modified ellipsoid method for conducting \( K \)-dimensional search and finding \( L^{*} \) vector. Similar to Section IV we start with “decoupled” scheme to solve the relaxed problem, via allowing \( L_{k} \)’s to be positive numbers.

A. Decoupled Scheme for Minimizing \( D_{a} \)

The essence of “decoupled” scheme is to solve the following two sub-problems in a sequential order:

1. **(SP5)**

\[
\min_{L_{k}, \forall k} D_{1}^{upb}(\{ L_{k} \}_{k=1}^{K}) \quad \text{subject to} \quad \sum_{k=1}^{K} L_{k} \leq B_{tot}, \quad L_{k} \in \mathbb{R}_{+}, \quad \forall k,
\]

2. **(SP6)**

\[
\min_{P_{k}, \forall k} D_{2}^{upb}(\{ P_{k} \}_{k=1}^{K}) \quad \text{subject to} \quad \sum_{k=1}^{K} P_{k} \leq P_{tot}, \quad P_{k} \in \mathbb{R}_{+}, \quad \forall k.
\]

Different from Section IV there is no iteration between (SP5) and (SP6). After solving (SP5) and (SP6), we take a similar approach to Section IV-B to migrate from continuous to integer solutions for \( L_{k} \)’s.

- **Solving (SP5):** Considering (13), we realize that minimizing \( D_{1}^{upb} \) is equivalent to minimizing \( \text{tr}(C_{\theta}^{T}Q_{\theta}C_{\theta}^{'}) = \sum_{k=1}^{K} \delta_{k} \sigma_{k}^{2}, \) where \( \delta_{k} \) is the squared Euclidean norm of the \( k \)-th row of \( C_{\theta} \). Since \( \sum_{k=1}^{K} \delta_{k} \sigma_{k}^{2} \) is a jointly convex function of \( L_{k} \)’s (See Appendix VIII-C) we use Lagrange multiplier method and solve the corresponding KKT conditions to find the solution. Also, \( \sum_{k=1}^{K} \delta_{k} \sigma_{k}^{2} \) is a decreasing function of \( L_{k} \)’s and \( B_{tot} \) (See Appendix VIII-C). Therefore, solving (SP5) in (29) for \( L_{k} \)’s and using the approximation \( 2L_{k} - 1 \approx 2L_{k} \) we reach:

\[
L_{k} = \left[ \log_{2} \left( \frac{\tau_{k}^{2} \delta_{k} \ln 2}{3 \nu_{k}} \right) \right]^{+}, \quad \forall k \quad \text{where} \quad \sum_{k=1}^{K} L_{k} = B_{tot}, \quad (31)
\]

\[
\nu^{*} = \frac{2 \ln 2}{3} \left[ 4 - B_{tot} \prod_{k=1}^{K} \delta_{k} \tau_{k}^{2} \right]^{+}.
\]

Substituting (32) into (31) one can verify:

\[
L_{k} = \left[ \frac{B_{tot}}{K} + \log_{2} \left( \frac{\tau_{k}^{2} \delta_{k}^{2}}{3 \nu_{k} \nu_{tot}^{2}} \right) \right]^{+}, \quad \forall k.
\]

Examining (33), we note that the first term inside the bracket is common among all sensors, whereas the second term differs among sensors and depends on \( \delta_{k}, \tau_{k} \). For \( \tau_{k} = \tau, \forall k, \) sensor \( k \) with a larger \( \delta_{k} \) (i.e., better observation quality) is allocated a larger \( L_{k} \). Note that, since \( D_{1}^{upb} \) does not capture communication channel errors, \( L_{k} \) in (33) is independent of sensor communication channel quality. This is different from solution of (SP2) in (18), where \( L_{k} \)’s depend on both sensor observation and communication channel qualities.

- **Solving (SP6):** Similar to (SP1) in (17), the objective function in (30) is a jointly convex function of \( P_{k} \)’s and also decreases as \( P_{k} \)’s and \( P_{tot} \) increase (See appendix VIII-B). Indeed, solving (SP6) yields the exact solution as that of (SP1), provided in (20) and (21).

- **Remark 6:** We minimize \( D_{1}^{upb} \) in (SP5) instead of \( D_{1} \), since it yields a closed form solution for \( L_{k} \)’s given in (33). In Section IV-B we discuss minimizing \( D_{a} = D_{1} + D_{2}^{upb} \), when we substitute (33) into \( D_{1} \) and (20) and (21), (33) into \( D_{2}^{upb} \).

B. Does Depleting \( B_{tot} \) Always Reduce \( D_{a} \)?

To answer this question, we consider the solution in (33) for asymptotic regime of large \( B_{tot} \). As \( B_{tot} \to \infty \), we find \( L_{k} \to \frac{B_{tot}}{K}, \forall k \), i.e., we should equally distribute \( B_{tot} \) among sensors. In situations where \( B_{tot} \) is large and communication channel quality of sensor \( k \) is poor (i.e., small \( \gamma_{k} \) due to small channel gain \( |h_{k}| \) or small \( P_{k} \) due to low \( P_{tot} \)), the solution in (33) can lead to a large value for \( D_{a} \), since sending a large number of bits \( L_{k} \) over poor quality channels increases communication channel errors and thus \( D_{2}^{upb} \). This observation suggests that perhaps, we should first find \( B_{opt} \) (for \( B_{opt} < B_{tot} \)), where \( B_{opt} \) depends on channel gains and \( P_{tot} \), and then distribute \( B_{opt} \) among sensors, to control the growth of \( D_{2}^{upb} \) in \( D_{a} \). In fact, when we substitute (33) into \( D_{1} \) and (20), (21), (33) into \( D_{2}^{upb} \), we find \( D_{1} \) is a decreasing function of \( B_{tot} \), whereas \( D_{2}^{upb} \) is an increasing function of \( B_{tot} \). As \( B_{tot} \to 0 \), \( D_{1} \) approaches its maximum value \( \text{tr}(C_{\theta}) \), i.e., trace of covariance of unknowns, whereas \( D_{2}^{upb} \) goes to
zero. On the other hand, as $B_{tot} \to \infty$, $D_1$ approaches its minimum value $d_0 = \text{tr}(C_a) - \text{tr}(C_{\psi}\Sigma^{-1}C_{\psi})$, i.e., clairvoi-
tant centralized estimation where unquantized sensor observations are available at the FC, whereas $D_2^{upb}$ grows unboundedly (See Appendix VIII-D). This tradeoff suggests that there should be a value $B^{opt}$ that minimizes $D_a$. Fig. 3 illustrates $D_1, D_2^{upb}, D_a$ versus $B_{tot}$ for two values $P_1^{tot}, P_2^{tot}$, where $P_2^{tot} \geq P_1^{tot}$. Fig. 3 shows that $B_2^{opt} \geq B_1^{opt}$. This observation can be explained as the following. Note that $D_1$ is independent of $P_{tot}$, whereas $D_2^{upb}$ increases as $P_{tot}$ increases (Appendix VIII-B shows $\frac{\partial D_2}{\partial P_{tot}} \leq 0 \forall k$, and thus $\frac{\partial D_2}{\partial B_{tot}} \leq 0$). Hence, as $P_{tot}$ increases we can transmit a larger number of bits, i.e., larger $B^{opt}$, without incurring an increase in communication channel errors.

Motivated by these, we propose “α-decoupled” algorithm. This algorithm starts with initiating $B^{opt} = 1$ and increasing the value of $B^{opt}$ by one bit at each iteration, where the maximum number of iterations is $B_{tot}$. At iteration $i$, we find $L(i)$’s using (33) and $P_k(i)$’s using (20), (21), substitute these $L(i)$’s, $P_k(i)$’s into $D_a$, and check if the decrease in $D_a$ in two consecutive iterations is less than zero, i.e., $D_a(\{L_k(i), P_k(i)\}_{k=1}^{K}) - D_a(\{L_k(i-1), P_k(i-1)\}_{k=1}^{K}) < 0$. If this inequality holds for $i < B_{tot}$, we let $B^{opt} = i$ and find the solution for $L_k$’s using (33) and $P_k$’s using (20), (21), when $B_{tot}$ is substituted with $B^{opt}$. Otherwise, we let $B^{opt} = B_{tot}$ and find the solution for $L_k$’s using (33) and $P_k$’s using (20), (21). At the end, we take the approach in Section V-B to migrate from continuous to integer solutions for rates and find the corresponding powers. Fig. 4 illustrates the behavior of “α-decoupled” algorithm and in particular, how $B^{opt}, D_1, D_2^{upb}, D_a$ vary as $P_{tot}$ increases. Note that as $P_{tot}$ increases $B^{opt}$ remains constant for certain (long) intervals and increases for some other (short) intervals of $P_{tot}$ values. The behavior of $B^{opt}$ versus $P_{tot}$ dictates the behavior of $D_1, D_2^{upb}, D_a$ as well. For the $P_{tot}$ intervals where $B^{opt}$ is fixed, $D_1$ is fixed as well, since it is independent of $P_{tot}$, whereas $D_2^{upb}$ and thus $D_a$ decrease if the decrease in $D_1$ intervals where $B^{opt}$ increases, $D_1$ decreases and $D_2^{upb}$ increases (Appendix VIII-D shows $\frac{\partial D_2}{\partial P_{tot}} \leq 0$ and $\frac{\partial D_2^{upb}}{\partial P_{tot}} \geq 0$). Overall, as $P_{tot}$ increases $D_a$ decreases, since the decrease in $D_1$, when $B^{opt}$ increases, dominates the increase in $D_2^{upb}$.

Regarding the modified “α-decoupled” algorithm a remark follows.

• Remark 7: The modified “α-decoupled” algorithm requires only one dimensional search to find $B^{opt}$ and thus $L_k$’s (33), as opposed to $K$-dimensional search required by the modified ellipsoid method in “α-coupled” algorithm. Also, finding $B^{opt}$ at most needs $B_{tot}$ number of iterations and no switching between solving (SP5) and (SP6) is needed.

C. Decoupled Scheme for Minimizing $D_b$

Note that “α-decoupled” algorithm still requires inversion of matrix $C_\psi + Q$ to calculate $\alpha_k$ and find $P_k$ using (20), (21). To eliminate this matrix inversion, we propose to minimize $D_2^{upb}$ instead of $D_2^{upb}$. Since $D_2^{upb}$ is a jointly convex function of $P_k$’s (see Appendix VIII-B), substituting $L_k$’s of (33) into $D_2^{upb}$ and minimizing it with respect to $P_k$’s, we reach the solution provided in (27), (28). Let “β-decoupled” algorithm be the one that minimizes $D_1^{upb}$ and $D_2^{upb}$ separately in $D_b$. This algorithm is very similar to “α-decoupled” algorithm described in Section V-B with the difference that when finding $B^{opt}$, at iteration $i$ we find $L_k(i)$’s using (33) and $P_k(i)$’s using (27), (28), substitute these $L_k(i), P_k(i)$’s into $D_a$, and check if the decrease in $D_b$ in two consecutive iterations is less than zero. After finding $B^{opt}$ we find the solution for $L_k$’s using (33) and $P_k$’s using (27), (28). The behavior of “β-decoupled” algorithm and in particular, how $B^{opt}, D_1^{upb}, D_2^{upb}, D_b$ vary as $P_{tot}$ increases, is similar to “α-decoupled” algorithm depicted in Fig. 4 and is omitted due to lack of space.

VI. NUMERICAL AND SIMULATION RESULTS

In this section through simulations we corroborate our analytical results. Without loss of generality and for the sake of illustration we set $K = 3$, $C_\theta = [1 \sqrt{2}/2); (\sqrt{2}/2) 2]$, $a_1 = [1 \pm 1.7], a_2 = [0.6 \ 0.6]^T, a_3 = [0.4 \ 0.4]^T, \sigma_{d_k} = 1$, $\sigma_{u_k} = 1$, $h_k = 1$, for all algorithms. “CS” and “DS” in the legends of the figures indicate the continuous solutions and discrete solutions of the algorithms, respectively.

Figs. 5 and 6 illustrate $\{10 \log_{10}(P_k)\}_{k=1}^{K}$ and $\{L_k\}_{k=1}^{K}$ vs. $P_{tot}$, respectively, for “α-coupled” algorithm and $B_{tot} = 30, 3$ bits. Figs. 5a and 6a for $B_{tot} = 30$ bits (abundant bandwidth) show that as $P_{tot}$ increases, both power and rate allocation approaches uniform allocation. This is in agreement with (22).
When $P_{\text{tot}}$ is small, only sensor 1 is active. As $P_{\text{tot}}$ increases sensors 2 and 3 become active in sequential order. Figs. 5b and 6b for $B_{\text{tot}} = 3$ bits (scarce bandwidth) show that only sensor 1 is active and $P_1 = P_{\text{tot}}$. Overall, these observations imply that power and rate allocation depends on both $P_{\text{tot}}$ and $B_{\text{tot}}$, e.g., when we have plentiful $P_{\text{tot}}$ and scarce $B_{\text{tot}}$ only the sensor with the largest observation gain is active. Also, uniform power and rate allocation is near optimal when we have ample $P_{\text{tot}}$ and $B_{\text{tot}}$. Figs. 7 and 8 depict $\{10 \log_{10}(P_k)\}_{k=1}^{3}$ and $\{L_k\}_{k=1}^{3}$ vs. $P_{\text{tot}}$ respectively, for “a-decoupled” and “a-decoupled” algorithms and $B_{\text{tot}} = 30$, 3 bits. Similar to “a-coupled” algorithm, we observe that when both $P_{\text{tot}}$ and $B_{\text{tot}}$ are abundant, uniform power and rate allocation is near optimal. This is in agreement with (22), (33). On the other hand, when $B_{\text{tot}}$ is scarce, power and rate allocation is way different from being uniform. In fact, when $P_{\text{tot}}$ is ample, (22) indicates that $P_k$ is proportional to $L_k$. Also, when $B_{\text{tot}}$ is scarce, (33) states that $L_k$’s and consequently $P_k$’s are not uniformly distributed. These indicate that power and rate allocation is affected by sensors’ observation qualities and channel gains, as well as both $P_{\text{tot}}$ and $B_{\text{tot}}$. There are two slight differences between “a-coupled” and “a-decoupled” algorithms: (i) for $B_{\text{tot}} = 30$ bits (ample bandwidth) sensors 2 and 3 become active at smaller $P_{\text{tot}}$ values in “a-decoupled” algorithm, (ii) for $B_{\text{tot}} = 3$ bits (scarce bandwidth), “a-decoupled” algorithm ultimately activates all sensors at $P_{\text{tot}}$ increases, while “a-coupled” algorithm only activates sensor 1. Note that for scarce bandwidth, even when $P_{\text{tot}}$ is very large, power and rate allocation in “a-decoupled” algorithm is non-uniform.

Figs. 9 and 10 depict $\{10 \log_{10}(P_k)\}_{k=1}^{3}$ and $\{L_k\}_{k=1}^{3}$ vs. $B_{\text{tot}}$, respectively, for “a-coupled” and $P_{\text{tot}} = 16, 30$ dB. The observations in these figures are in full agreement with the former ones. In particular, for $P_{\text{tot}} = 30$ dB (large power), when $B_{\text{tot}}$ is small, only sensor 1 is active. As $B_{\text{tot}}$ increases, sensors 2 and 3 become active too, in a way that power and rate allocation approaches uniform for large $B_{\text{tot}}$. On the other hand, for $P_{\text{tot}} = 16$ dB only sensor 1 is active and $P_1 = P_{\text{tot}}$. Figs. 11 and 12 illustrate $\{10 \log_{10}(P_k)\}_{k=1}^{3}$ and $\{L_k\}_{k=1}^{3}$ vs. $B_{\text{tot}}$, respectively, for “a-decoupled” and $P_{\text{tot}} = 16, 30$ dB. While the behaviors of “a-coupled” and “a-decoupled” have similarities, they have differences as the following: (i) for $P_{\text{tot}} = 30$ dB sensors 2 and 3 become active at smaller $B_{\text{tot}}$ value in “a-decoupled” algorithm, (ii) for $P_{\text{tot}} = 16$ dB, “a-decoupled” algorithm ultimately activates all sensors as $B_{\text{tot}}$ increases, while “a-coupled” algorithm only activates sensor 1. Note for $P_{\text{tot}} = 16$ dB, even when $B_{\text{tot}}$ is very large, power and rate allocation in “a-decoupled” algorithm is non-uniform. this is because $B_{\text{opt}} < B_{\text{tot}}$ in this case and according to (33), (20), (21) power and rate allocation would be non-uniform.

In Fig. 13 we plot $D_a$ when implementing “a-coupled” and “a-decoupled” and $D_b$ when implementing “b-coupled” and “b-decoupled” algorithms, vs. $B_{\text{tot}}$, for $P_{\text{tot}} = 30, 16$ dB. Fig. 14 depicts the simulated MSE when “a-coupled”, “b-coupled”, “a-decoupled” and “b-decoupled” algorithms are implemented for power and rate allocation vs. $B_{\text{tot}}$ for $P_{\text{tot}} = 30, 3$ bits. Similar observations to those of Fig. 13 are made, with a few differences: (i) “b-coupled” outperforms “a-decoupled” algorithm in very low $P_{\text{tot}}$, (ii) the simulated MSE obtained by “b-coupled”, “a-decoupled”, and “b-decoupled” algorithms approaches the same value for $B_{\text{tot}} = 3$ bits and large $P_{\text{tot}}$. The reason perhaps is that the discretized quantization rates are the same for these algorithms and according to (22) for large $P_{\text{tot}}$, $P_k$’s of these algorithms become identical.

To better see the behavior of the upper bounds with respect to the simulated MSE, Figs. 15 and 16 plot the simulated MSE and upper bounds vs. $P_{\text{tot}}$ for all the proposed algorithms (note that Figs. 15 and 16 have the same curves as Figs. 13 and 14). We observe that when $P_{\text{tot}}$ and $B_{\text{tot}}$ are not too low, the upper bounds are good approximations of the simulated MSE.

Fig. 17 depicts $D_a$ when implementing “a-coupled” and “a-decoupled” and $D_b$ when implementing “b-coupled” and “b-decoupled” algorithms, vs. $B_{\text{tot}}$, for $P_{\text{tot}} = 30, 16$ dB. Fig. 18 depicts the simulated MSE when “a-coupled”, “b-coupled”, “a-decoupled” and “b-decoupled” algorithms are implemented for power and rate allocation vs. $B_{\text{tot}}$ for $P_{\text{tot}} = 30, 16$ dB. We make similar observations and conclusions to those we made for Fig. 14. For $P_{\text{tot}} = 30$ dB and large $B_{\text{tot}}$, performance of all algorithms reaches the clairvoyant benchmark $d_0$. On the other hand, for $P_{\text{tot}} = 16$ dB and large $B_{\text{tot}}$, there is a persistent gap with $d_0$ for each algorithm, due to communication channel errors. When comparing Figs. 17 and 18 we note that the behavior of the bounds $D_a$ and $D_b$ vs. $B_{\text{tot}}$ is very similar to that of the simulated MSE.

VII. CONCLUSIONS

We considered distributed estimation of a Gaussian vector with a known covariance matrix and linear observation model, where the FC is tasked with reconstruction of the unknowns, using a linear estimator. Sensors employ uniform multi-bit quantizers and BPSK modulation, and communicate with the FC over power- and bandwidth-constrained channels. We derived two closed-form upper bounds on the MSE, in terms of the optimization parameters (i.e., transmit power and quantization rate per sensor). Each bound consists of two

“b-decoupled” algorithm when $B_{\text{tot}} = 3$ bits and $13 < P_{\text{tot}} < 18$ dB). For small $P_{\text{tot}}$, the performance of each algorithm does not change as we decrease $B_{\text{tot}} = 30$ bits to $B_{\text{tot}} = 3$ bits.

This observation can be explained as the following. For small $P_{\text{tot}}$, the communication channels cannot support reliable transmission of large number of bits. Hence, the algorithms allocate few bits to sensors and increasing $B_{\text{tot}}$ does not improve the performance. Another observation is that for $B_{\text{tot}} = 30$ bits (plentiful bandwidth) and large $P_{\text{tot}}$, performance of all algorithms reaches the clairvoyant benchmark $d_0$, whereas for $B_{\text{tot}} = 3$ bits (scarce bandwidth) and large $P_{\text{tot}}$ there is a persistent gap with $d_0$ for each algorithm, due to quantization errors, and “a-coupled” and “b-decoupled” algorithms perform the best and the worst, respectively.
terms, where the first term is the MSE due to observation noises and quantization errors, and the second term is the MSE due to communication channel errors. We proposed “coupled” and “decoupled” resource allocation schemes that minimize these bounds. The “coupled” schemes utilize the iterative modified ellipsoid method to conduct K-dimensional search and find the quantization rate vector, whereas the “decoupled” ones rely on one-dimensional search to find the quantization rates. Our simulations show that when $P_{tot}$ and $B_{tot}$ are not too scarce, the bounds are good approximations of the actual MSE. Through simulations, we verified the effectiveness of the proposed schemes and confirmed that their performance approaches the cloud-centric centralized estimation for large $P_{tot}$ and $B_{tot}$ ($P_{tot} \approx 25 \text{ dB}, B_{tot} \approx 30 \text{ bits}$). Our results indicate that resource allocation is affected by sensors’ observation qualities, channel gains, as well as $P_{tot}$ and $B_{tot}$, e.g., two WSNs with identical conditions and $P_{tot}$ ($B_{tot}$) and different $B_{tot}$ ($P_{tot}$) require two different power (rate) allocation. Also, more number of bits and transmit power are allotted to sensors with better observation qualities.

VIII. APPENDIX

A. Finding Upper Bound on $\mathbb{E}\{\hat{m}_k - m_k\}$

Suppose the bit sequence representations of $m_k$ and $\hat{m}_k$ are, respectively, $(b_{k,1}, \ldots, b_{k,L_k})$ and $(\hat{b}_{k,1}, \ldots, \hat{b}_{k,L_k})$, i.e., $m_k = \Delta_k(0.5 - 2^{L_k-1}) + \sum_{j=1}^{L_k} b_{k,j} 2^{L_k-1-j}$ and $\hat{m}_k = \Delta_k(0.5 - 2^{L_k-1}) + \sum_{j=1}^{L_k} \hat{b}_{k,j} 2^{L_k-1-j}$. Therefore:

$$\mathbb{E}\{\hat{m}_k - m_k\}^2 = \Delta_k^2 \mathbb{E}\{\sum_{j=1}^{L_k} 2^{L_k-j} (b_{k,j} - \hat{b}_{k,j})^2\}$$

\begin{align*}
&\leq \Delta_k^2 L_k (4^{L_k} \sum_{j=1}^{L_k} 4^{-j} \mathbb{E}\{(b_{k,j} - \hat{b}_{k,j})^2\}) \\
&\leq \frac{p_c \Delta_k^2 L_k (4^{L_k} (1 - (1/4)L_k)^2)}{3} \\
&\leq \frac{4p_c L_k \Delta_k^2}{3} \leq \exp(-\frac{p_c L_k \Delta_k^2}{3})
\end{align*}

where (a) comes from Cauchy’s inequality $(\sum_j \alpha_j \beta_j)^2 \leq (\sum_j \alpha_j^2)(\sum_j \beta_j^2)$ for arbitrary $\alpha_j, \beta_j$’s, and the fact that $(b_{k,j} - \hat{b}_{k,j})^2$ is a Bernoulli random variable with success probability $p_c$. (b) is due to sum of a geometric series, (c) is found using the definition of $\Delta_k$ and $1 - (1/4)L_k < 1$, and (d) is obtained since $p_c = \mathbb{Q}(\sqrt{2 \gamma_k P_k / L_k})$ and $\mathbb{Q}(x) \leq \exp(-x^2)$. These imply that $D_{2,upb}^{upb}$ is a decreasing function of $P_k$’s and also a jointly convex function of $P_k$’s. Similarly:

$$\frac{\partial^2 D_{2,upb}^{upb}}{\partial P_k \partial P_l} = \begin{cases} 0, & k \neq l \\
\frac{\alpha_k \gamma_k \exp(-\frac{\gamma_k P_k}{L_k})}{L_k}, & k = l \end{cases}$$

C. Properties of $\sum_{k=1}^{K} \delta_k \sigma_{e_k}^2$

One can verify the following:

$$\frac{\partial^2 (\sum_{k=1}^{K} \delta_k \sigma_{e_k}^2)}{\partial L_k \partial L_l} = \begin{cases} 0, & k \neq l \\
\frac{\delta_k \gamma_k \exp(-\frac{\gamma_k P_k}{L_k})}{L_k}, & k = l \end{cases}$$

These imply that $D_{1,upb}^{upb}$ is a decreasing function of $L_k$’s and also a jointly convex function of $L_k$’s.

D. More Properties on $D_1$ and $D_{2,upb}^{upb}$

- $D_1$ is a decreasing function of $B_{tot}$: after some mathematical manipulations, one can show

$$\frac{\partial D_1}{\partial B_{tot}} = \text{tr}(G\frac{\partial Q}{\partial B_{tot}} G^T) = \sum_{k=1}^{K} |\frac{\partial Q}{\partial B_{tot}}|_{k,k} \|\sigma_k^2\|_2 \leq 0,$$

where after substituting (33) into $Q$ we find $[\frac{\partial Q}{\partial B_{tot}}]_{k,k} = -2 \ln 2 \frac{\gamma_k P_k}{L_k} \Delta_k^2$. Since $B_{tot} \rightarrow 0$, $[Q]_{k,k} \rightarrow \infty$, i.e., all eigenvalues of $(C_x + Q)^{-1}$ go to infinity. Consequently, due to Weyl’s inequality (24) all eigenvalues of $(C_x + Q)^{-1}$ go to zero. Since $(C_x + Q)^{-1}$ is a diagonalizable matrix, this means $(C_x + Q)^{-1}$ goes to an all-zero matrix and $D_1 \rightarrow \text{tr}(C_0)$. On the other hand, as $B_{tot} \rightarrow \infty$, $[Q]_{k,k} \rightarrow 0$ and thus $D_1 \rightarrow 0 = \text{tr}(C_0) = -\text{tr}(C_0^T C_0)$.

- $D_{2,upb}^{upb}$ is an increasing function of $B_{tot}$: after some mathematical manipulations, one can verify

$$\frac{\partial D_{2,upb}^{upb}}{\partial B_{tot}} = \text{tr}(G\frac{\partial \mathcal{M}'}{\partial B_{tot}} G^T) + \text{tr}(G(B+B^T)G^T)$$

where $B = -\frac{\partial Q}{\partial B_{tot}}(C_x + Q)^{-1} \mathcal{M}'$. Substituting (33) into $\mathcal{M}'$ we find $[\frac{\partial \mathcal{M}'}{\partial B_{tot}}]_{k,k} = \frac{\partial \mathcal{M}'}{\partial B_{tot}} = 4 \frac{\partial Q}{\partial B_{tot}} \exp(-\frac{\gamma_k P_k}{L_k})[1 + \frac{2 \gamma_k P_k}{L_k}] \geq 0$. Hence, $\text{tr}(G\frac{\partial \mathcal{M}'}{\partial B_{tot}} G^T) \geq 0$ and the first term in (34) is non-negative. Next we show that the second term in (34) is also non-negative and hence $\frac{\partial D_{2,upb}^{upb}}{\partial B_{tot}} \geq 0$. Since $G^T G$ and $B+B^T$ are symmetric matrices and $G^T G \succeq 0$, using inequality (2) of (27) we obtain:

$$\text{tr}(G(B+B^T)G^T) = \text{tr}(G G^T (B+B^T)^T) \succeq \lambda_{min}(G G^T) \text{tr}(B+B^T)$$

where $\lambda_{min}(G G^T) \geq 0$. Furthermore,

$$\text{tr}(B+B^T) = 2 \text{tr}(B) = 2 \text{tr}(\mathcal{M}'(-\frac{\partial Q}{\partial B_{tot}})(C_x + Q)^{-1}) \geq 2 \lambda_{min}(\mathcal{M}'(-\frac{\partial Q}{\partial B_{tot}})) \text{tr}((C_x + Q)^{-1}) \geq 0$$
in which (c), (f) above are found since $\mathcal{M}'(-\frac{\partial Q}{\partial P_t})$ and $(C_x+Q)^{-1}$ are symmetric and positive definite matrices. As $B_{tot} \to 0$, $[\mathcal{M}']_{k,k} \to 0$ and $G, G^T$ go to all-zero matrices and therefore $D_{2}^{pb} \to 0$. On the other hand, as $B_{tot} \to \infty$, $[\mathcal{M}']_{k,k} \to \infty$ and $G \to CT_0 C_x^{-1}$ and therefore $D_{2}^{pb} \to \infty$.
