Big data for health care is one of the potential solutions to deal with the numerous challenges of health care, such as rising cost, aging population, precision medicine, universal health coverage, and the increase of non-communicable diseases. However, data centralization for big data raises privacy and regulatory concerns.

Covered topics include (1) an introduction to privacy of patient data and distributed learning as a potential solution to preserving these data, a description of the legal context for patient data research, and a definition of machine/deep learning concepts; (2) a presentation of the adopted review protocol; (3) a presentation of the search results; and (4) a discussion of the findings, limitations of the review, and future perspectives.

Distributed learning from federated databases makes data centralization unnecessary. Distributed algorithms iteratively analyze separate databases, essentially sharing research questions and answers between databases instead of sharing the data. In other words, one can learn from separate and isolated datasets without patient data ever leaving the individual clinical institutes.

Distributed learning promises great potential to facilitate big data for medical application, in particular for international consortiums. Our purpose is to review the major implementations of distributed learning in health care.

The methodology for this research is that distributed machine learning is an evolving field in computing, with 665 articles published between 2001 and 2018; the study is based on a literature search, focuses on the medical applications of distributed machine learning, and provides an up-to-date summary of the field.

THE LEGAL CONTEXT FOR PATIENT DATA RESEARCH

The challenges in law and ethics in relation to big data and artificial intelligence are well documented and discussed. The issue is one of balance: privacy of health data and access to data for research. This issue is likely to become more pronounced with the foreseeable developments in health care, notably in relation to rising cost, aging population, precision medicine, universal health coverage, and the increase of noncommunicable diseases. However, recent developments in law, for example, in the European Union’s General Data Protection Regulation (GDPR), appear to maintain the traditional approach that seems to favor individualism above solidarity. Individualism is strengthened in the new legislation. There is
Distributed learning allows learning from medical data while guaranteeing preservation of patient privacy.

Relevance
Distributed learning allows learning from medical data while guaranteeing preservation of patient privacy.

MACHINE LEARNING
Machine learning comes from the possibility to apply algorithms on raw data to acquire knowledge. These algorithms are implemented to support decision making in different domains, including health care, manufacturing, education, financial modeling, and marketing. In medical disciplines, machine learning has contributed to improving the efficiency of clinical trials and decision-making processes. Some examples of machine learning applications in medicine are the localization of thoracic diseases, early diagnosis of Alzheimer disease, personalized treatment, and automated radiology reports.

There are three main categories of machine learning algorithms. First, in supervised learning, the algorithm generates a function for mapping input variables to output variables. In unsupervised learning, the applied algorithms do not have any outcome variable to estimate, and the algorithms generate a function mapping the structure of the data. The third type is referred to as reinforcement learning, whereby in the absence of a training dataset the algorithm trains itself by learning from experiences to make increasingly improved decisions. A reinforcement agent decides what action to perform to accomplish a given task. Table 1 provides a brief description of selected popular machine learning algorithms across the three categories.

DEEP LEARNING
Deep learning is a subset of machine learning, which, in turn, is a subset of artificial intelligence as represented in Figure 1. The learning process of a deep neural network architecture cascades through multiple nodes in multiple layers, where nodes and layers use the output of the previous nodes and layers as input. The output of a node is calculated by applying an activation function to the weighted average of this node’s input. As described by Andrew Ng, “The analogy to deep learning is that the rocket engine is the deep learning models and the fuel is the huge amounts of data that we can feed in to these algorithms,” meaning that the more data are fed into the model the better the performance. Yet, this continuous improvement of the performance in concordance with the
TABLE 1. Examples of Machine Learning Algorithms

| Example             | Algorithm | Description                                                                                                                                                                                                 | Distributed Algorithm Available? |
|---------------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| Supervised learning | SVM       | An algorithm performing classification tasks by composing hyperplanes in a multidimensional space that separates cases of different class labels. SVM supports both regression and classification tasks and can handle multiple continuous and categorical variables. | Yes\(^5\)                       |
|                     | Logistic regression | An algorithm used for discrete values estimation tasks based on a given set of independent variables. In simple words, it predicts the probability of occurrence of an event by fitting data to a logit function that maps probabilities with values lying between 0 and 1. Hence, it is also known as logit regression. | Yes\(^83,85\)                   |
|                     | Decision tree  | A nonparametric method used for both classification and regression problems. As the name suggests, it uses a tree-like decision model by splitting a dataset into two or more subsets on the basis of conditional control statements. It can also be used to visually represent decision-making processes. | Yes\(^86,87\)                   |
|                     | Random forest | Random forest is a method performing classification and regression tasks. A random forest is a composition of two initials: forest because it represents a collection of decision trees, and random because the forest randomly selects observations and features from which it puts up various decision trees. The results are then averaged. Each decision tree in the forest has access to a random set of the training data, chooses a class, and the most selected class is then the predicted class. | No                              |
|                     | KNN        | KNN can be used for regression problems; however, it is widely used for classification problems. In KNN, the assumption is that similar data elements are close to each other. Given K (positive integer) and a test observation, KNN first groups the K closest elements to the test observation. Then, in the case of regression, it returns the mean of the K labels, or in the case of classification, it returns the mode of the K labels. | Yes\(^88,89\)                   |
| Unsupervised learning | K-mean  | An algorithm mainly used for clustering in data mining. K-means nomination comes from its functionality, which is partitioning of N observations to K clusters, where each and every observation is part of the cluster with the nearest mean. | Yes\(^90,93\)                   |
|                     | Apriori algorithm | A classic algorithm in data mining. Used for mining frequent item groups and relevant association rules in a transactional database. | Yes\(^94\)                      |

### TABLE 1. Examples of Machine Learning Algorithms (Continued)

| Example                | Algorithm | Description                                                                                                                                                                                                 | Available? |
|------------------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| Reinforcement learning | MDP       | Introduced in 1950s, MDP is a discrete stochastic control process providing a framework for modeling decision making when final outcomes are ambiguous. Given $S_0$ (current state) and $S$ (new state), the decision process is made by steps. The process has a state at each step and the decision maker can choose any available action in $S_0$. The process then moves randomly into $S$, the new state. The chosen action influences the probability of moving from $S_0$ to $S$. In other words, the next state depends only on the current state, not the previous states, and the action taken by the decision maker, satisfying the Markovian property, from which comes the algorithm’s name. | No        |
| Q-learning             |           | Useful for optimization of action selection of any finite MDP. Q-learning algorithm provides agents in a process the ability to know what action to take under what situation. | Yes       |

Abbreviations: KNN, K-nearest neighbors; MDP, Markov decision process; SVM, support vector machine.
Distributed Machine Learning

A large quantity of training data is required for machine learning to be applied, especially in outcome modeling, where multiple factors influence learning. Provided there are sufficient and appropriate data, machine learning typically results in accurate and generalizable models. However, the sensitivity of the personal data greatly hinders the conventional centralized approach to machine learning, whereby all data are gathered in a single data store. Distributed machine learning resolves legal and ethical privacy concerns by learning without the personal data ever leaving the firewall of the medical centers.

The euroCAT and ukCAT projects are a proof of distributed learning being successfully implemented into clinical settings to overcome data access restrictions. The purpose of the euroCAT project was to predict patient outcomes (eg, post-radiotherapy dyspnea for patients with lung cancer) by learning from data stored within clinics without sharing any of the medical data.

Distributed Deep Learning

Training a deep learning model typically requires thousands to millions of data points and is therefore computationally expensive as well as time consuming. These challenges can be mitigated with different approaches. First, because it is possible to train deep learning models in a parallelized fashion, using dedicated hardware (graphics processing units, tensor processing units) reduces the computational time. Second, as the memory of this dedicated hardware is often limited, it is possible to divide the training data into subsets called batches. In this situation, the training process iterates over the batches, only considering the data of one batch at each iteration. On top of easing the computing burden, using small batches during training improves the model’s ability to generalize.

These approaches address computation challenges but do not necessarily preserve data privacy. As for machine learning, deep learning can be distributed to protect patient data. Moreover, distributed deep learning also improves computing performance, as in the case of wireless sensor networks, where centralized learning is inefficient in terms of both communication and energy.

An example of distributed deep learning in the medical domain is that of Chang et al, who deployed a deep learning model across four medical institutions for image classification purposes using three distinct datasets: retinal fundus, mammography, and ImageNet. The results were compared with the same deep learning model trained on centrally hosted data. The comparison showed that the distributed model accuracy is similar to the centrally hosted model. In a different study, McClure et al developed a distributed deep neural network model to reproduce FreeSurfer brain segmentation. FreeSurfer is an open source tool for preprocessing and analyzing (segmentation,
| Reference | Data and Target | Methods and Distributed Learning Approach | Tools | Accomplishments and Results |
|-----------|----------------|------------------------------------------|-------|-----------------------------|
| Jochems61 | Clinical data from 287 patients with lung cancer, treated with curative intent with CRT or RT alone, were collected and stored in five different medical institutes: MAASTRO (the Netherlands), Jessa (Belgium), Liège (Belgium), Aachen (Germany), and Eindhoven (the Netherlands). | A Bayesian network model is adapted for distributed learning using data from five hospitals. | Varian learning portal | AUC, 0.61 |
| Target: predict dyspnea. | Patient data were extracted and stored locally in the hospitals. Only the weights were then sent to the master server. | | | |
| Deist23 | Clinical data from 268 patients with NSCLC from five different medical institutes: Aachen (Germany), Eindhoven (The Netherlands), Hasselt (Belgium), Liège (Belgium), and Maastricht (the Netherlands). | Alternating Direction Method of Multipliers was used to learn SVM models. | Varian learning portal | AUC, 0.62 for training set and 0.66 for validation set |
| Target: predict dyspnea grade ≥ 2. | The data were processed simultaneously in local databases. Then, the updated model parameters were sent to the master machine to compare and update them and check if the learning process has converged. The process is repeated until convergence criteria were met. | | | |
| Dluhos56 | 258 patients with first-episode schizophrenia and 222 healthy controls originating from four datasets were collected: two datasets from University Hospital Brno (Czech Republic), University Medical Center Utrecht (The Netherlands), and the last dataset originates from the Prague Psychiatric Center and Psychiatric Hospital Bohnice. | All images were preprocessed: normalized, segmented, and standardized. | VBM8 toolbox | Joint and meta models had similar classification performance, which was better than performance of local models. |
| Target: classification of patients with first-episode schizophrenia | Create four local SVM models. Then create multisample models (joint model and meta model) based on the individual models created previously. This process was repeated four times, by setting each time three training datasets, with remaining one as the validation set. | MATLAB statistics and machine learning toolbox | | |

| Jochems63 | Clinical data from 698 patients with lung cancer, treated with curative intent with CRT or RT alone were collected and stored in two medical institutes: MAASTRO (Netherlands) and Michigan University (United States). | Distributed learning for a Bayesian network using data from three hospitals | Varian learning portal | AUC, 0.662 |
|           | Target: prediction of NSCLC 2-year survival after radiation therapy | The model used the T category and N category, age, total tumor dose, and WHO performance for predictions. | | The discriminative performance of centralized and distributed models on the validation set was similar. |
| Brisimi65 | Electronic health records from Boston Medical Center of patients with at least one heart-related diagnosis between 2005 and 2010. The data are distributed between 10 hospitals. | Soft-margin l1-regularized sparse SVM classifier. Not provided | | AUC, 0.56 |
|           | Target: prediction of heart cardiac events. | | | Developed an iterative cPDS algorithm for solving the large-scale SVM problem in a decentralized fashion. The system then predicted patient’s hospitalization for cardiac events in upcoming calendar year. cPDS converged faster than centralized methods. |
| Tagliaferri64 | 227 variables extracted from thyroid cancer data from six Italian cancer centers. Each has four properties: name, form, type of field, and levels. | Inferential regression analysis. | COBRA framework | Thyroid COBRA: based on COBRA-Storage System. A new software BOA “Beyond Ontology” supporting two different models: Cloud-based large database model and distributed learning model |

Abbreviations: AUC, area under the curve; BOA, Beyond Ontology Awareness; COBRA, Consortium for Brachytherapy Data Analysis; cPDS, cluster Primal Dual Splitting; CRT, chemoradiation; NSCLC, non–small-cell lung cancer; RT, radiotherapy; SVM, support vector machine.
thickness estimation, and so on) of human brain magnetic resonance images. The results demonstrated performance improvement on the test datasets. Similar to the previous study, a brain tumor segmentation was successfully performed using distributed deep learning across 10 institutions (BraTS distribution).

In the matter of distributed deep learning, the training weights are combined to train a final model, and the raw data are never exposed. In the case of sharing the locale gradients, it might be possible to retrieve estimations of the original data from these gradients. Training the local models on batches may prevent retrieving all the data from the gradients, as these gradients correspond to single batches rather than all the local data. However, setting an optimal batch size needs to be considered to assure data safety and the model’s ability to generalize.

**PRIVACY AND INTEGRATION OF DISTRIBUTED LEARNING NETWORKS**

Privacy in a distributed learning network addresses three main areas: data privacy, the implemented model’s privacy, and the model’s output privacy. Data privacy is achieved by means of data anonymization and data never leaving the medical institutions. The distributed learning model can be secured by applying differential privacy techniques, preventing leakage of weights during the training, and cryptographic techniques. These cryptographic techniques provide a set of multiparty protocols that ensure security of the computations and communication. Once the model is ready, not only can the network participants use it to learn from their data, but this learning should be able to be performed locally and under highly private and secure conditions to protect the model’s output.

The users of a machine/deep learning model are not necessarily the model’s developers. Hence, documentation and the integration of automated data eligibility tests have two important assets:

- The documentation ensures providing a clear view of what the model is designed for, a technical description of the model, and its use.
- The eligibility tests are important to ensure that correct input data are extracted and provided before executing the model. In euroCAT, a distributed learning expert installed quality control via data extraction pipelines at every participant point in the network. The pipeline automatically allowed data records fulfilling the model training eligibility criteria to be used in the training. The experts also test the extraction pipeline thoroughly in addition to the machine learning testing. However, there were post-processing compensation methods to correct for the variations caused by using different local protocols.

**DISCUSSION**

If one examines oncology, for instance, cancer is clearly one of the greatest challenges facing health care. More than 16 million new cancer cases were reported in 2017 alone. This number climbed to 18.1 million cases in 2018. This
increasing number of cancer incidences means that there are undoubtedly sufficient data worldwide to put machine/deep learning to meaningful work. However, as highlighted earlier, this requires access to the data and, as also highlighted earlier, distributed learning enables this in a manner that resolves legal and ethical concerns. Nonetheless, integration of distributed learning into health care is much slower compared with other fields, which raises the question of why this should be. Here, we summarize a set of methodologies to facilitate the adoption of distributed learning and provide future directions.

CURRENT STATE OF MEDICAL DATA STORAGE AND PREPROCESSING

Information Communication Technology

Every hospital has its own storage devices and architecture. In this case, the information communication technology preparation for distributed learning requires significant energy, time, and manpower, which can be costly. This same process (data acquisition and preprocessing) needs to be repeated for each participating hospital, and subsequently development and adoption of medical data standardization protocols need to be developed for this implementation process.

Make the Data Readable: Findable, Accessible, Interoperable, Reusable Data Principles

One way to enable a virtuous circle network effect is to embrace another community engaged in synergistic activities (joining a distributed learning network is worthwhile if it links to another large network). The Findable, Accessible, Interoperable, Reusable (FAIR) Guiding Principles for data management and stewardship have gained substantial interest, but delivering scientific protocols and workflows that are aligned with these principles is significant. A description of FAIR principles is represented in Figure 3. Technological solutions are urgently needed that will enable researchers to explore, consume, and produce FAIR data in a reliable and efficient manner, to publish and reuse computational workflows, and to define and share scientific protocols as workflow templates. Such solutions will address emerging concerns about the nonreproducibility of scientific research, particularly in data science (eg, poorly published data, incomplete workflow descriptions, limited ability to perform meta-analyses, and an overall lack of reproducibility). Because workflows are fundamental to research activities, FAIR has broad applicability, which is vital in the context of distributed learning with medical data.

WHY NOT PUBLICLY SHARE MEDICAL DATA?

Some studies were conducted trying to facilitate and secure data-sharing procedures to encourage related researchers and organizations to publicly share their data and embrace transparency by proposing data-sharing procedures and protocols aiming to harmonize regulatory frameworks and research governance. Despite the efforts made toward data-sharing globalization, the sociocultural issues surrounding data sharing remain pertinent. Large clinical trials also face limitations in the data collection capabilities because of limited data storage capacities and manpower. To retrospectively perform additional analysis, all the participating centers need to be contacted again, which is time consuming and delays research.

Furthermore, medical institutions prefer not to share patient data to ensure privacy protection. This is, of course, in no small part about ensuring the trust and confidence of patients who display a wide range of sensitivities toward the use of their personal data.

ORGANIZATIONAL CHANGE MANAGEMENT

The adoption of distributed learning will require a change in organizational management (such as making use of newest data standardization techniques and adapting the roles of employees to more technically oriented tasks, such as data retrieval). Provided knowledge and understanding of proper change management concepts, health care providers can implement the latter successfully. Change management principles, such as defining a global vision, networking, and continuous communicating, could facilitate the integration of new technologies and bring up the clinical capabilities. However, this process of change management can be complicated, because it requires the involvement of multiple health care centers from different countries and continents. This diversity can trigger a fear of loss (one of the major factors of financial decision making), which stems from differences of opinion and regulation, and the absence of data standardization, making the processes of data acquisition and preprocessing harder. In addition, the lack of knowledge about the new technology leads to resistance to accept the change and innovation. Therefore, it is important to help health care organizations understand the need for distributed learning by explaining the context of the change in terms of traditional ways of learning to distributed learning and...
a long-term vision of the improvements that it can bring, including time and money savings for both hospitals and patients. This could in turn improve patient lives, in addition to conducting more studies on research databases to consolidate proof of safety and quality of distributed models.

As can be seen in Table 2, distributed learning has been applied to train different models that can predict different outcomes for a variety of pathologies, including lung cancer, thyroid cancer, heart cardiac events, and schizophrenia, in addition to the continuous development of tools and algorithms facilitating the adoption of distributed learning, such as the variant learning portal, the alternating direction method of multipliers algorithm, as well as the application of FAIR data principles. The cited studies provide a proof that distributed learning can ensure patient data privacy and guarantee that accurate models are built that are the equivalent of centralized models.

LIMITATIONS OF THE EXISTING DISTRIBUTED LEARNING IMPLEMENTATIONS

A shared limitation of the studies presented in Table 2 is that the number of institutes involved in the distributed network is rather small. The size of the network varies from four to 10 institutions. With few medical institutes involved, the models were trained using the data of only a few hundred patients. By promoting the use of distributed learning, it should instead be possible to train the models using data from thousands or even millions of patients.

FUTURE PERSPECTIVES

An automated monitoring system accessible by the partners or medical centers participating in the distributed learning network can promote transparency, traceability, and trust. Recent advances of information technology, such as blockchain, can be integrated into a distributed learning network. Blockchain allows trusted partners to visualize the history of the transactions and actions taken in the distributed network. This integration of blockchain should help in easing the resistance to the new distributed technology among health care workers as it provides both provenance and enforceable governance.

In 2008, Satoshi Nakamoto introduced the concept of a peer-to-peer electronic cash system known as Bitcoin. Blockchain was made famous as the public transaction ledger of this cryptocurrency. It ensures security by using cryptography in a decentralized, immutable distributed ledger technology. It is easy to manage as it can be made public, whereby any individual can participate, or it can be made private, where all participants are known to each other. It is an efficient monitoring system, as records cannot be deleted from the chain. By these means, blockchain exceeds its application as a cryptocurrency to a permanent trustful tracing system.

In 2008, Satoshi Nakamoto introduced the concept of a peer-to-peer electronic cash system known as Bitcoin. Blockchain was made famous as the public transaction ledger of this cryptocurrency. In 2008, Satoshi Nakamoto introduced the concept of a peer-to-peer electronic cash system known as Bitcoin. Blockchain was made famous as the public transaction ledger of this cryptocurrency. It ensures security by using cryptography in a decentralized, immutable distributed ledger technology. It is easy to manage as it can be made public, whereby any individual can participate, or it can be made private, where all participants are known to each other. It is an efficient monitoring system, as records cannot be deleted from the chain. By these means, blockchain exceeds its application as a cryptocurrency to a permanent trustful tracing system. Figure 4 illustrates a visual representation of blockchain.

Boulos et al. demonstrated how blockchain could be used to contribute in health care: securing patient information and provider identities, managing health supply chains,
monetizing clinical research and data (giving patients the choice to share), processing claims, detecting fraud, and managing prescriptions (replace incorrect and outdated data). In addition to the above-mentioned uses of blockchain, it has been also used to maintain security and scalability of clinical data sharing, secure medical record sharing, prevent drug counterfeiting, and secure a patient’s location.

It is essential that the use of distributed machine/deep learning and blockchain be harmonized with the available security-preserving technologies (ie, continues development and cybersecurity), which begins at the user levels (use strong passwords, connect using only trusted networks, and so on) and ends with more complex information technology infrastructures (such as data anonymization and user ID encryption). Cybersecurity is a key aspect in preserving privacy and ensuring safety and trust among patients and health care systems. The continuous development or postmarketing surveillance can be seen as the set of checks and integrations that should occur when a distributed learning network is launched. This practice should make it possible to identify any weak security measures in the network or non-up-to-date features that may require re-implementation.

The distributed learning and blockchain technologies presented here show that there are emerging data science solutions that begin to meet the concerns and shortcomings of the law. The problems of re-identification are greatly reduced and managed through the technologies. Clearly, there are conceptual issues of understanding the impact of these technologies on privacy, and the relationship between privacy and confidentiality, but there are significant technical developments for the regulators to consider that could answer a number of their concerns.

SUMMARY

Currently, a combination of regulations and ethics makes it difficult to share data even for scientific research purposes. The issues relate to the legal basis for processing and anonymization. Specifically, there has been reluctance to move away from informed consent as the legal basis for processing toward processing in the public interest, and there are concerns about the re-identification of individuals where data are de-identified and then shared in aggregated environments. A solution could be to allow researchers to train their machine learning programs without the data ever having to leave the clinics, which in this paper we have established as distributed learning. This safe practice makes it possible to learn from medical data and can be applied across various medical disciplines. A limitation to its application, however, is that medical centers need to be convinced to participate in such practice, and regulators also need to know suitable safeguards have been established. Moreover, as can be seen in Table 2, even with the use of distributed learning, the size of the data pool learned from remains rather small. In the future, the integration of blockchain technology to distributed learning networks could be considered, as it ensures transparency and traceability while following FAIR data principles and can facilitate the implementation of distributed learning.

FIG A1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2009 flow diagram.
**TABLE A2. PRISMA 2009 Checklist**

| Section/Topic                          | No. | Checklist Item                                                                 | Reported on Page No. |
|----------------------------------------|-----|-------------------------------------------------------------------------------|----------------------|
| **Title**                              |     |                                                                               |                      |
| Title                                   | 1   | Identify the report as a systematic review, meta-analysis, or both.            | 1                    |
| **Abstract**                           |     |                                                                               |                      |
| Structured summary                     | 2   | Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number. | 1                    |
| **Introduction**                       |     |                                                                               |                      |
| Rationale                              | 3   | Describe the rationale for the review in the context of what is already known. | 1-5                  |
| Objectives                             | 4   | Provide an explicit statement of questions being addressed with reference to PICOS. | 2                    |
| **Methods**                            |     |                                                                               |                      |
| Protocol and registration              | 5   | Indicate if a review protocol exists, if and where it can be accessed (eg, Web address), and, if available, provide registration information including registration number. | 5                    |
| Eligibility criteria                   | 6   | Specify study characteristics (eg, PICOS, length of follow-up) and report characteristics (eg, years considered, language, publication status) used as criteria for eligibility, giving rationale. | 5                    |
| Information sources                    | 7   | Describe all information sources (eg, databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched. | 5                    |
| **Search**                             |     |                                                                               |                      |
| Search                                 | 8   | Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated. | 5                    |
| **Study selection**                    |     |                                                                               |                      |
| Study selection                        | 9   | State the process for selecting studies (ie, screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis). | 5 (and Fig A1)       |
| Data collection process                | 10  | Describe method of data extraction from reports (eg, piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators. | 5                    |
| **Data items**                         |     |                                                                               |                      |
| Data items                             | 11  | List and define all variables for which data were sought (eg, PICOS, funding sources) and any assumptions and simplifications made. | N/A                  |
| **Risk of bias in individual studies** | 12  | Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level) and how this information is to be used in any data synthesis. | N/A                  |
| **Summary measures**                   | 13  | State the principal summary measures (eg, risk ratio, difference in means).     | N/A                  |
| **Synthesis of results**               | 14  | Describe the methods of handling data and combining results of studies, if done, including measures of consistency (eg, $I^2$) for each meta-analysis. | 5                    |
| **Risk of bias across studies**        | 15  | Specify any assessment of risk of bias that may affect the cumulative evidence (eg, publication bias, selective reporting within studies). | N/A                  |
| **Additional analyses**                | 16  | Describe methods of additional analyses (eg, sensitivity or subgroup analyses, meta-regression), if done, indicating which were prespecified. | N/A                  |
| **Results**                            |     |                                                                               |                      |
| Study selection                        | 17  | Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram. | 5 (and Fig A1)       |
| Study characteristics                  | 18  | For each study, present characteristics for which data were extracted (eg, study size, PICOS, follow-up period) and provide the citations. | 5-8                  |

(Continued on following page)
| Section/Topic                      | No. | Checklist Item                                                                                                                                                                                                 | Reported on Page No. |
|-----------------------------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| Risk of bias within studies       | 19  | Present data on risk of bias of each study and, if available, any outcome-level assessment (see item 12).                                                                                                           | N/A                 |
| Results of individual studies     | 20  | For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group, and (b) effect estimates and confidence intervals, ideally with a forest plot.            | 5-8                 |
| Synthesis of results              | 21  | Present results of each meta-analysis done, including confidence intervals and measures of consistency.                                                                                                          | 5-8                 |
| Risk of bias across studies       | 22  | Present results of any assessment of risk of bias across studies (see Item 15).                                                                                                                                   | N/A                 |
| Additional analysis               | 23  | Give results of additional analyses, if done (eg, sensitivity or subgroup analyses, meta-regression [see Item 16]).                                                                                                   | N/A                 |
| Discussion                        |     |                                                                                                                                                                                                                   |                     |
| Summary of evidence               | 24  | Summarize the main findings, including the strength of evidence for each main outcome; consider their relevance to key groups (eg, health care providers, users, and policy makers).                                    | 8                   |
| Limitations                       | 25  | Discuss limitations at study and outcome level (eg, risk of bias), and at review level (eg, incomplete retrieval of identified research, reporting bias).                                                            | 10                  |
| Conclusions                       | 26  | Provide a general interpretation of the results in the context of other evidence, and implications for future research.                                                                                               | 11                  |
| Funding                           |     |                                                                                                                                                                                                                   |                     |
| Funding                           | 27  | Describe sources of funding for the systematic review and other support (eg, supply of data); role of funders for the systematic review.                                                                          | 11                  |

Abbreviations: N/A, not applicable; PICOS, participants, interventions, comparisons, outcomes, and study design; PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-Analyses.
