1. Introduction

The completion \( \mathcal{G}_\Gamma \) of a finite index subgroup \( \Gamma \) of \( \text{SL}_2(\mathbb{Z}) \) with respect to the inclusion \( \rho : \Gamma \hookrightarrow \text{SL}_2(\mathbb{Q}) \) is a proalgebraic group, defined over \( \mathbb{Q} \), which is an extension

\[
1 \to \mathcal{H}_\Gamma \to \mathcal{G}_\Gamma \to \text{SL}_2 \to 1
\]

Date: March 26, 2014.
Supported in part by grant DMS-1005675 from the National Science Foundation.
of \( SL_2 \) by a prounipotent group \( U_\Gamma \), and a Zariski dense homomorphism \( \Gamma \to \mathcal{G}_\Gamma(\mathbb{Q}) \). The main result of [16] implies that, for each choice of a base point of the associated modular curve \( X_\Gamma \), the coordinate ring \( \mathcal{O}(\mathcal{G}_\Gamma) \) has a canonical mixed Hodge structure (MHS) that is compatible with its product, coproduct and antipode. This MHS induces one on the Lie algebra \( \mathfrak{g}_\Gamma \) of \( \mathcal{G}_\Gamma \).\(^1\)

In this paper we give a detailed exposition of the construction and basic properties of the natural MHS on (the coordinate ring and Lie algebra of) relative completions of modular groups. Part 1 is an exposition of the basic properties of relative completion. It also contains a direct construction of the MHS on the relative completion of the fundamental group (and, more generally, of path torsors) of a smooth affine (orbi) curve with respect to the monodromy representation of a polarized variation of Hodge structure (PVHS). Part 2 is an exploration of the MHS on relative completions of modular groups and their associated path torsors, especially in the case of the full modular group \( SL_2(\mathbb{Z}) \).

Completions of modular groups are interesting because of their relationship to modular forms and to categories of admissible variations of MHS over modular curves. Because the inclusion \( \Gamma \to SL_2(\mathbb{Q}) \) is injective, one might expect the prounipotent radical \( U_\Gamma \) of \( \mathcal{G}_\Gamma \) to be trivial. However, this is not the case. Its Lie algebra \( \mathfrak{u}_\Gamma \) is a pronilpotent Lie algebra freely topologically generated (though not canonically) by

\[
\prod_{m \geq 0} H^1(\Gamma, S^m H)^* \otimes S^m H
\]

where \( H \) denotes the defining representation of \( SL_2 \) and \( S^m H \) its \( m \)th symmetric power. Because \( H^1(\Gamma, S^m H) \) is a space of modular forms of \( \Gamma \) of weight \( m + 2 \) (Eichler-Shimura), there should be a close relationship between the MHS on \( \mathcal{G}_\Gamma \) and the geometry and arithmetic of elliptic curves.

To explain the connection with admissible variations of MHS, consider the category \( \text{MHS}(X_\Gamma, \mathbb{H}) \) of admissible variations of MHS \( \mathcal{V} \) over \( X_\Gamma \) whose weight graded quotients have the property that the monodromy representation

\[
\Gamma \to \text{Aut} \mathcal{G}_\Gamma^{W_m} \mathcal{V}
\]

factors through an action of the algebraic group \( SL_2 \) for all \( m \). The monodromy representation

\[
\Gamma \cong \pi_1(X_\Gamma, x) \to \text{Aut} V_x
\]

of such a variation \( \mathcal{V} \) factors through the canonical homomorphism \( \Gamma \to \mathcal{G}_\Gamma(\mathbb{Q}) \), so that one has a natural coaction

\[
(1.2) \quad V_x \to V_x \otimes \mathcal{O}(\mathcal{G}_\Gamma).
\]

In Section 8 we show that there is an equivalence of categories between \( \text{MHS}(X_\Gamma, \mathbb{H}) \) and the category of “Hodge representations” of \( \mathcal{G}_\Gamma \) — that is the category of representations of \( \Gamma \) on a MHS \( \mathcal{V} \) that induce a homomorphism \( \mathcal{G}_\Gamma \to \text{Aut} \mathcal{V} \) for which the coaction (1.2) is a morphism of MHS. The prounipotent radical \( U_\Gamma \) of \( \mathcal{G}_\Gamma \), and hence modular forms, control extensions in \( \text{MHS}(X_\Gamma, \mathbb{H}) \). This result holds in much greater generality and was proved with Matsumoto, Pearlstein and Terasoma. Full details of the general case will appear elsewhere.

\(^1\)There is more structure: if \( X_\Gamma \) is defined over the number field \( K \) and if \( x \in X_\Gamma \) is a \( K \)-rational point, then one also has a Galois action on \( \mathcal{G} \otimes \mathbb{Q}_\ell \). This and the canonical MHS on \( \mathcal{G}_\Gamma \) should be the Hodge and \( \ell \)-adic étale realizations of a motivic structure on \( \mathcal{G} \) that depends on \( x \).
Modular forms give simple extensions in $MHS(X_\Gamma, \mathbb{H})$. The fundamental representation $H$ of $SL_2$ corresponds to the polarized variation of Hodge structure $\mathbb{H}$ of weight 1 over $X_\Gamma$ whose fiber over the point $x \in X_\Gamma$ is the first cohomology group of the corresponding elliptic curve. The classification of admissible variations of MHS over $X_\Gamma$ in the previous paragraph and the computation (1.1) imply that there are extensions of variations

$$0 \to H^1(X_\Gamma, S^m\mathbb{H})^* \otimes S^m\mathbb{H} \to \mathbb{E} \to \mathbb{Q} \to 0.$$  

When $\Gamma$ is a congruence subgroup, this variation splits as the sum of extensions

$$0 \to \tilde{M}_f \otimes S^m\mathbb{H} \to \mathbb{E}_f \to \mathbb{Q} \to 0,$n

where $f$ is a normalized Hecke eigen form of weight $m + 2$, $M_f$ is the corresponding Hodge structure, and $\tilde{M}_f = M_f(m+1)$ is its dual. When $f$ is a cusp form, $\tilde{M}_f \otimes S^m\mathbb{H}$ has weight $-1$. In the case where $\Gamma = SL_2(\mathbb{Z})$, we give an explicit construction of these extensions and the corresponding normal functions in Section 13.4. When $f$ is an Eisenstein series, $\tilde{M}_f = \mathbb{Q}(m + 1)$ and the extension is of the form

$$0 \to S^m\mathbb{H}(m + 1) \to \mathbb{E}_f \to \mathbb{Q} \to 0.$$

These extensions are constructed explicitly in Section 13.3 when $\Gamma = SL_2(\mathbb{Z})$. They correspond to the elliptic polylogarithms of Beilinson and Levin [2].

This work also generalizes and clarifies Manin’s work on “iterated Shimura integrals” [32, 33]. The exact relationship is discussed in Section 13.2. The periods of the MHS on $O(\mathcal{G}_\Gamma)$ are iterated integrals (of the type defined in [16]) of the logarithmic forms in Zucker’s mixed Hodge complex that computes the MHS on the cohomology groups $H^1(X_\Gamma, S^m\mathbb{H})$, whose definition is recalled in Section 6. Manin’s iterated Shimura integrals are iterated integrals of elements of the subcomplex of holomorphic forms in Zucker’s complex. They form a Hopf algebra whose spectrum is a quotient $\mathcal{U}_A$ of $\mathcal{U}_\Gamma$ by the normal subgroup generated by $F^0\mathcal{U}_\Gamma$. This quotient is not motivic as it does not support a MHS for which the quotient mapping $\mathcal{U}_\Gamma \to \mathcal{U}_A$ is a morphism of MHS. There is a further quotient $\mathcal{U}_B$ of $\mathcal{U}_A$ that is dual to the Hopf algebra generated by iterated integrals of Eisenstein series. In Section 19 we show that it is not motivic by relating it to the Eisenstein quotient of $\mathcal{U}_\Gamma$, described below.

Fix a base point $x \in X_\Gamma$, so that $\mathcal{G}_\Gamma$ denotes the completion of $\pi_1(X_\Gamma, x) \cong \Gamma$ with its natural MHS. The “Eisenstein quotient” $\mathcal{G}_\Gamma^{\text{cusp}}$ of $\mathcal{G}_\Gamma$, defined in Section 16, is the maximal quotient of $\mathcal{G}_\Gamma$ whose Lie algebra $\mathfrak{g}_\Gamma^{\text{cusp}}$ has a MHS whose weight graded quotients are sums of Tate twists of the natural Hodge structure on $S^nH_x$. Its isomorphism type does not depend on the base point $x$. As $x$ varies in $X_\Gamma$, the coordinate rings of the Eisenstein quotients form an admissible VMHS over $X_\Gamma$.

Denote the Lie algebra of $\mathcal{U}_B$ by $\mathfrak{u}_B$ and of the of the pronimpotent radical $\mathcal{G}_\Gamma^{\text{cusp}}$ by $\mathfrak{u}_\Gamma^{\text{cusp}}$. Since the Hodge structure $M_f \otimes S^nH_x$ associated to an eigen cusp form $f$ is not of this type, such Hodge structures will lie in the kernel of

$$H_1(\mathfrak{u}_\Gamma^{\text{cusp}}) \to H_1(\mathfrak{u}_\Gamma^{\text{cusp}}),$$

which implies that $H_1(\mathfrak{u}_\Gamma^{\text{cusp}})$ is generated by one copy of $S^nH_x(m + 1)$ for each normalized Eisenstein series of weight $m + 2$. In particular, when $\Gamma = SL_2(\mathbb{Z}),$

$$H_1(\mathfrak{u}_\Gamma^{\text{cusp}}) \cong \prod_{n \geq 1} S^{2n}H_x(2n + 1).$$
There is a natural projection $\mathcal{U}_B \to \mathcal{U}^{\text{eis}}_\Gamma$ from Manin’s quotient of $\mathcal{U}_\Gamma$ to $\mathcal{U}^{\text{eis}}_\Gamma$ that induces an isomorphism
\[ H_1(\mathcal{U}_B) \cong H_1(\mathcal{U}^{\text{eis}}_\Gamma). \]

But, as we show in Section 19, the cuspidal generators $\tilde{M}_f \otimes S^{2n} H_x$ of $\mathcal{U}_\Gamma$ become non-trivial relations in $\mathcal{U}^{\text{eis}}_\Gamma$. Such relations were suggested by computations in the $\ell$-adic étale version with Makoto Matsumoto (cf. [24]). Evidence for them was provided by Aaron Pollack’s undergraduate thesis [36] in which he found relations in the image of the representation $\text{Gr}^W_u \mathcal{U}^{\text{eis}}_\Gamma \to \text{Der}_L(H)$ induced by the natural action of $\mathcal{U}^{\text{eis}}_\Gamma$ on the the unipotent fundamental group of a once punctured elliptic curve, which we construct in Section 15. The arguments in Section 19 and the computations of Terasoma [46] (Thm. 19.3) imply that Pollack’s quadratic relations also hold in $\mathcal{U}^{\text{eis}}_\Gamma$. Since $\mathcal{U}_B$ is free and since $\mathcal{U}^{\text{eis}}_\Gamma$ is not, Manin’s quotient $\mathcal{U}_B$ does not support a natural MHS.

The starting point for much of this work is the theory of “universal mixed elliptic motives” [24] developed with Makoto Matsumoto. The starting point of that project was a computation in 2007 of the $\ell$-adic weighted completion of $\pi_1(M_{1,1}/\mathbb{Z}[1/\ell])$ in which we observed that cuspidal generators of the relative completion of the geometric fundamental group of $M_{1,1}/\mathbb{Z}[1/\ell]$ appeared to become relations in the weighted completion of its arithmetic fundamental group. Pollack’s thesis [36] added evidence that these cuspidal generators had indeed become relations in the weighted completion. The discussion in Section 20 gives a Hodge theoretic explanation of these relations and shows that they are motivic.

Finally, we mention related work by Levin and Racinet [31], Brown and Levin [4], and Calaque, Enríquez and Etingof [6], and subsequent work of Enríquez.

Although the paper contains many new results, it is expository. The intended audience is somebody who is familiar with modern Hodge theory. Several standard topics, such as a discussion of modular symbols, are included to fix notation and point of view, and also to make the paper more accessible. The reader is assumed to be familiar with the basics of mixed Hodge structures, their construction and their variations, including the basics of computing limit mixed Hodge structures.

Acknowledgments: It is a pleasure to acknowledge the mathematicians with whom I have had fruitful discussions, which have helped shape my view of the subject of these notes. In particular, I would like to thank my long term collaborator, Makoto Matsumoto, as well as Aaron Pollack and Francis Brown. I am particularly indebted to Tomohide Terasoma who communicated his significant result, Theorem 19.3.

1.1. Notation and Conventions.

1.1.1. Path multiplication and iterated integrals. In this paper we use the topologist’s convention (which is the opposite of the algebraist’s convention) for path multiplication. Two paths $\alpha, \beta : [0, 1] \to X$ are composable when $\alpha(1) = \beta(0)$. The product $\alpha * \beta$ of two composable paths first traverses $\alpha$ and then $\beta$.

Denote the complex of smooth forms on the smooth manifold $M$ by $E^*(M)$. Iterated integrals are defined using Chen’s original definition: if $\omega_1, \ldots, \omega_r \in E^1(M) \otimes A$ are 1-forms on a manifold $X$ that take values in an associative algebra $A$ and
\( \alpha : [0, 1] \to M \) is a piecewise smooth path, then
\[
\int_{\alpha} \omega_1 \omega_2 \cdots \omega_r = \int_{\Delta^r} f_1(t_1) \cdots f_r(t_r) dt_1 dt_2 \cdots dt_r.
\]
where \( f_j(t) dt = \alpha^* \omega_j \) and \( \Delta^r \) is the "time ordered" \( r \)-simplex
\[
\Delta^r = \{ (t_1, \ldots, t_r) \in \mathbb{R}^n : 0 \leq t_1 \leq t_2 \leq \cdots \leq t_r \leq 1 \}.
\]
An exposition of the basic properties of iterated integrals can be found in [14, 18].

1.1.2. Filtrations. The lower central series (LCS) \( L^* G \) of a group \( G \) is defined by
\[
G = L^1 G \supseteq L^2 G \supseteq L^3 G \supseteq \cdots
\]
where \( L^{m+1} G = [G, L^m G] \). Its associated graded \( \text{Gr}^*_\text{LCS} G \) is a graded Lie algebra over \( \mathbb{Z} \) whose \( m \)th graded quotient is \( \text{Gr}^m_{\text{LCS}} G := L^m G / L^{m+1} G \).

The lower central series \( L^* g \) of a Lie algebra \( g \) is defined similarly. A Lie algebra \( g \) is nilpotent if \( L^N g = 0 \) for some \( N \geq 0 \).

1.1.3. Hodge theory. All mixed Hodge structures will be \( \mathbb{Q} \)-mixed Hodge structures unless otherwise stated. The category of \( \mathbb{Q} \)-mixed Hodge structures will be denoted by \( \text{MHS} \). The category of \( \mathbb{R} \)-mixed Hodge structures will be denoted by \( \text{MHS}_{\mathbb{R}} \).

Often we will abbreviate mixed Hodge structure by MHS, variation of MHS by VMHS, mixed Hodge complex by MHC, cohomological MHC by CMHC. The category of admissible VMHS over a smooth variety \( X \) will be denoted by \( \text{MHS}(X) \).

2. Preliminaries

2.1. Proalgebraic groups. In this paper, the term algebraic group will refer to a linear algebraic group. Suppose that \( F \) is a field of characteristic zero. A proalgebraic group \( G \) over \( F \) is an inverse limit of algebraic \( F \)-groups \( G_{\alpha} \). The coordinate ring \( O(G) \) of \( G \) is the direct limit of the coordinate rings of the \( G_{\alpha} \). The Lie algebra \( g \) of \( G \) is the inverse limit of the Lie algebras \( g_{\alpha} \) of the \( G_{\alpha} \). It is a Hausdorff topological Lie algebra. The neighbourhoods of 0 are the kernels of the canonical projections \( g \to g_{\alpha} \).

The continuous cohomology of \( g = \varinjlim g_{\alpha} \) is defined by
\[
H^* (g) := \varprojlim H^* (g_{\alpha}).
\]
Its homology is the full dual:
\[
H_* (g) := \text{Hom}_F (H^* (g), F) \cong \varprojlim H_* (g_{\alpha})
\]
Each homology group is a Hausdorff topological vector space; the neighbourhoods of 0 are the kernels of the natural maps \( H_* (g) \to H_* (g_{\alpha}) \).

Continuous cohomology can be computed using continuous Chevalley-Eilenberg cochains:
\[
C^* (g) = \text{Hom}_{F^{\text{cts}}}^*(\Lambda^* g, F) := \varprojlim \text{Hom}_F (\Lambda^* g_{\alpha}, F)
\]
with the usual differential.

If, instead, \( g = \bigoplus_m g_m \) is a graded Lie algebra, then the homology and cohomology of \( g \) are also graded. This follows from the fact that the grading of \( g \) induces a grading of the Chevalley-Eilenberg chains and cochains of \( g \).
2.2. Pronipotent groups and pronilpotent Lie algebras. A pronipotent $F$-group is a proalgebraic group that is an inverse limit of unipotent $F$-groups. A pronilpotent Lie algebra over a $F$ is an inverse limit of finite dimensional nilpotent Lie algebras. The Lie algebra of a pronipotent group is a pronilpotent Lie algebra. The functor that takes a pronipotent group to its Lie algebra is an equivalence of categories between the category of unipotent $F$-groups and the category of pronilpotent Lie algebras over $F$.

The following useful result is an analogue for pronilpotent Lie algebras of a classical result of Stallings [43]. A proof can be found in [19, §3].

**Proposition 2.1.** For a homomorphism $\varphi : n_1 \to n_2$ of pronilpotent Lie algebras, the following are equivalent:

(i) $\varphi$ is an isomorphism,
(ii) $\varphi^* : H^*(n_2) \to H^*(n_1)$ is an isomorphism,
(iii) $\varphi^* : H^j(n_2) \to H^j(n_1)$ is an isomorphism when $j = 1$ and injective when $j = 2$.

□

Another useful fact that we shall need is the following exact sequence, which is essentially due to Sullivan [45].

**Proposition 2.2.** If $n$ is a pronilpotent Lie algebra over $F$, then the sequence

$$0 \to \text{Gr}^2_{\text{LCS}} n^* \xrightarrow{[\cdot, \cdot]^*} \Lambda^2 H^1(n) \xrightarrow{\text{cup}} H^2(n)$$

is exact, where $(\cdot)^* = \text{Hom}^{\text{cts}}(\ , F)$.

2.3. Free Lie algebras. Suppose that $F$ is a field of characteristic 0 and that $V$ is a vector space over $F$. Here we are not assuming $V$ to be finite dimensional. The free Lie algebra generated by $V$ will be denoted by $L(V)$. It is characterized by the property that a linear map $V \to g$ into a Lie algebra over $F$ induces a unique Lie algebra homomorphism $L(V) \to g$. The Poincaré-Birkhoff-Witt Theorem implies [40] that $L(V)$ is the Lie subalgebra of the tensor algebra $T(V)$ (with bracket $[A, B] = AB - BA$) generated by $V$ and that the inclusion $L(V) \to T(V)$ induces an isomorphism $UL(V) \to T(V)$ from the enveloping algebra of $L(V)$ to $T(V)$. The cohomology of $L(V)$ with trivial coefficients vanishes in degrees $> 1$.

If $\mathfrak{g}$ is a Lie algebra, then any splitting of the projection $\mathfrak{g} \to H_1(\mathfrak{g})$ induces a homomorphism $L(H_1(\mathfrak{g})) \to \mathfrak{g}$. If $\mathfrak{g}$ is free, then this homomorphism is an isomorphism [40]. It induces a canonical isomorphism

$$\text{Gr}^\bullet_{\text{LCS}} \mathfrak{g} \cong L(H_1(\mathfrak{g}))$$

of the the graded Lie algebra associated to the lower central series (LCS) of $\mathfrak{g}$ with the free Lie algebra generated by its first graded quotient $H_1(\mathfrak{g}) = \mathfrak{g}/L^2\mathfrak{g}$.

The free completed Lie algebra $L(V)^\wedge$ generated by $V$ is defined to be

$$L(V)^\wedge = \lim_{\leftarrow n} L(n),$$

where $n$ ranges over all finite dimensional nilpotent quotients of $L(V)$. It is viewed as a topological Lie algebra. It is useful to note that there is a canonical isomorphism

$$L(V)^\wedge = \lim_{\leftarrow \hat{W}} L(W)/L^nL(W)$$
of topological Lie algebras, where \( W \) ranges over all finite dimensional quotients of \( V \) and \( n \) over all positive integers.

We can regard \( V \) as a topological vector space — the neighbourhoods of 0 are the subspaces of \( V \) of finite codimension. Every continuous linear mapping \( V \to u \) induces a unique continuous homomorphism \( \mathbb{L}(V)^\wedge \to \mathbb{u} \). The continuous cohomology of \( \mathbb{L}(V)^\wedge \) vanishes in positive degrees.

If \( n \) is a pronilpotent Lie algebra, then any continuous section of the quotient mapping \( n \to H_1(n) \) induces a continuous surjective homomorphism \( \mathbb{L}(H_1(n))^\wedge \to n \). Applying Proposition 2.1 to this homomorphism, we obtain:

**Proposition 2.4.** A pronilpotent Lie algebra is free if and only if \( H^2(n) = 0 \). □

Part 1. Completed Path Torsors of Affine Curves

3. Relative Completion in the Abstract

Suppose that \( \Gamma \) is a discrete group and that \( R \) is a reductive algebraic group over a field \( F \) of characteristic zero. The completion of \( \Gamma \) relative to a Zariski dense representation \( \rho : \Gamma \to R(F) \) is a proalgebraic \( F \)-group \( G \) which is an extension

\[
1 \to U \to G \to R \to 1
\]

of \( R \) by a pronipotent group \( U \), and a homomorphism \( \Gamma \to G(F) \) such that the composite

\[
\Gamma \xrightarrow{\hat{\rho}} G(F) \xrightarrow{\rho} R(F)
\]

is \( \rho \). It is universal for such groups: if \( G \) is a proalgebraic \( F \) group that is an extension of \( R \) by a pronipotent group, and if \( \phi : \Gamma \to G(F) \) is a homomorphism whose composition with \( G \to R \) is \( \rho \), then there is a homomorphism \( \hat{\phi} : G \to G \) of proalgebraic \( F \)-groups such that the diagram

\[
\begin{array}{ccc}
\Gamma & \xrightarrow{\rho} & G(F) \\
\phi \downarrow & & \downarrow \hat{\phi} \\
G(F) & \xrightarrow{\phi} & R(F)
\end{array}
\]

commutes.

When \( R \) is trivial, \( \rho \) is trivial and \( G = U \) is the unipotent completion of \( \Gamma \) over \( F \).

Relative completion can be defined as follows: Let \( \mathcal{L}(\Gamma, R) \) denote the category of finite dimensional \( F \)-linear representations \( V \) of \( \Gamma \) that admit a filtration

\[
0 = V_0 \subset V_1 \subset \cdots \subset V_N = V
\]

by \( \Gamma \)-submodules with the property that each graded quotient \( V_j/V_{j-1} \) is an \( R \)-module and the action of \( \Gamma \) on it factors through \( \rho \). It is a neutral tannakian category. The completion of \( \Gamma \) relative to \( \rho \) is the fundamental group of this category with respect to the fiber functor that takes a representation to its underlying vector space.

We will generally be sloppy and not distinguish between a proalgebraic group \( G \) and its group \( G(F) \) of \( F \)-rational points. For example, in the context of relative completion, \( \rho \) will be a homomorphism \( \Gamma \to R \).
3.1. **Levi splittings.** The following generalization of Levi’s Theorem implies that the relative completion $G$ of a finitely generated group $\Gamma$ can be expressed (non-canonically) as a semi-direct product $G \cong R \rtimes U$. The Lie algebra $u$ of $U$ is then a pronilpotent Lie algebra in the category of $R$-modules. The isomorphism type of $G$ is determined by $u$ with its $R$-action.

Suppose that $F$ is a field of characteristic 0 and that $R$ is a reductive $F$-group. Call an extension $1 \to U \to G \to R \to 1$ of $R$ by a prounipotent group in the category of affine $F$-groups quasi-finite if for all finite dimensional $R$-modules $V$, $\text{Hom}_R(V, H_1(U))$ is finite dimensional. The results in the following section imply that the completion of a finitely generated group $\Gamma$ relative to a homomorphism $\rho : \Gamma \to R(F)$ is a quasi finite extension of $R$.

**Proposition 3.1.** Every quasi-finite extension of $R$ by a prounipotent group $U$ is split. Moreover, any two splittings are conjugate by an element of $U(F)$.

**Sketch of Proof.** The classical case where $U$ is an abelian unipotent group (i.e., a finite dimensional vector space) was proved by Mostow in [35]. (See also, [3, Prop. 5.1].)

First consider the case where $U$ is an abelian proalgebraic group. The quasi-finiteness assumption implies that there are (finite dimensional) abelian unipotent groups $U_\alpha$ with $R$-action and an $R$-equivariant isomorphism $U \cong \prod_\alpha U_\alpha$.

The extension of $G$ by $U$ can be pushed out along the projection $U \to U_\alpha$ to obtain extensions $1 \to U_\alpha \to G_\alpha \to R \to 1$. The classical classical case, stated above, implies that each of these has a splitting $s_\alpha$ and that this splitting is unique up to conjugation by an element of $U_\alpha$. These sections assemble to give a section $s = (s_\alpha)$ of $G \to R$ that is defined over $F$. Every section of $G \to R$ is of this form. Any two are conjugate by an element of $U(F)$.

To prove the general case, consider the extensions
\begin{equation}
1 \to U_n \to G_n \to R \to 1.
\end{equation}

where $G_n = G/L^{n+1}U$, $U_n = U/L^{n+1}U$, and where $L^nU$ denotes the $n$th term of the LCS of $U$. The result is proved by constructing a compatible sequence of sections of these extensions. We have already established the $n = 1$ case. Suppose that $n > 1$ and that we have constructed a splitting of $s_{n-1}$ of $G_{n-1} \to R$ and shown that any two such splittings are conjugate by an element of $U_{n-1}$.

Pulling back the extension
\begin{equation}
1 \to \text{Gr}_{LCS}^n U \to G_n \to G_{n-1} \to 1
\end{equation}
along $s_{n-1}$ gives an extension
\begin{equation}
1 \to \text{Gr}_{LCS}^n U \to G \to R \to 1.
\end{equation}
The quasi-finite assumption implies that the $R$-module $\text{Gr}_{LCS}^n U$ is a product of finite dimensional $R$-modules. The $n = 1$ case implies that this extension is split and that any two splittings are conjugate by an element of $\text{Gr}_{LCS}^n U$. If $s$ is a section
of $G \to R$, then the composition of $s$ with the inclusion $G \to G_n$ is a section $s_n$ of (3.2) that is compatible with $s_{n-1}$:

$$
\begin{array}{cccccccc}
1 & \longrightarrow & Gr^n L CS U & \longrightarrow & G & \longrightarrow & R & \longrightarrow & 1 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
1 & \longrightarrow & Gr^n L CS U & \longrightarrow & G_n & \longrightarrow & G_{n-1} & \longrightarrow & 1
\end{array}
$$

The uniqueness of $s$ implies that any two such lifts of $s_{n-1}$ are conjugate by an element of $Gr^n L CS U(F)$. This and the fact that $s_{n-1}$ is unique up to conjugation by an element of $U(F)$ implies that $s_n$ is as well. □

3.2. Cohomology. We continue with the notation above, where $\mathcal{G}$ is the relative completion of $\Gamma$. When $R$ is reductive, the structure of $g$ and $u$ are closely related to the cohomology of $\Gamma$ with coefficients in rational representations of $R$. We will assume also that $H^j(\Gamma,V)$ is finite dimensional when $j \leq 2$ for all rational representations $V$ of $R$. This condition is satisfied when $\Gamma$ is finitely presented and thus by fundamental groups of all complex algebraic varieties.

For each rational representation $V$ of $R$ there are natural isomorphisms

$$
\text{Hom}_{R^{\text{cts}}}^\bullet(H^\bullet(u),V) \cong [H^\bullet(u) \otimes V]^R \cong H^\bullet(g,V)^{\pi_0(R)}.
$$

The homomorphism $\Gamma \to G(F)$ induces a homomorphism

$$
H^\bullet(g,V)^{\pi_0(R)} \to H^\bullet(\Gamma,V)
$$

It is an isomorphism in degrees $\leq 1$ and an injection in degree 2.

Denote the set of isomorphism classes of finite dimensional irreducible representations of $R$ by $\bar{\mathcal{R}}$. Fix an $R$-module $V_\lambda$ in each isomorphism class $\lambda \in \bar{\mathcal{R}}$. If each irreducible representation of $R$ is absolutely irreducible\(^2\) and if $H^j(\Gamma,V)$ is finite dimensional for all rational representations $V$ of $R$, then (3.3) implies that there is an isomorphism

$$
\prod_{\lambda \in \bar{\mathcal{R}}} [H^1(\Gamma,V_\lambda)]^* \otimes_F V_\lambda \cong H_1(u)
$$

of topological modules, and that there is a continuous $R$-invariant surjection

$$
\prod_{\lambda \in \bar{\mathcal{R}}} [H^2(\Gamma,V_\lambda)]^* \otimes_F V_\lambda \to H_2(u).
$$

In both cases, the LHS has the product topology.

3.3. Base change. When discussing the mixed Hodge structure on a relative completion of the fundamental group of a complex algebraic manifold $X$, we need to be able to compare the completion of $\pi_1(X,x)$ over $\mathbb{R}$ (or $\mathbb{Q}$) with its completion over $\mathbb{C}$. For this reason we need to discuss the behaviour of relative completion under base change.

The cohomological properties of relative completion stated above imply that it behaves well under base change. To explain this, suppose that $K$ is an extension field of $F$. Then $\rho_K : \Gamma \to \hat{R}(K)$ is Zariski dense in $R \times_F K$, so one has the completion $\mathcal{G}_K$ of $\Gamma$ relative to $\rho_K$. It is an extension of $R \times_F K$ by a prounipotent group. The universal mapping property of $\mathcal{G}_K$ implies that the homomorphism

\(^2\)This is the case when $R = \text{Sp}_g$ over any field of characteristic zero.
\( \Gamma \to \mathcal{G}(K) \) induces a homomorphism \( \mathcal{G}_K \to \mathcal{G} \times_F K \) of proalgebraic \( K \)-groups. The fact that (3.3) is an isomorphism in degree 1 and injective in degree 2 implies that this homomorphism is an isomorphism.

3.4. Examples. Here the coefficient field \( F \) will be \( \mathbb{Q} \). But because of base change, the discussion is equally valid when \( F \) is any field of characteristic 0.

3.4.1. Free groups. Suppose that \( \Gamma \) is a finitely generated free group and that \( \rho : \Gamma \to R(F) \) is a Zariski dense reductive representation. Denote the completion of \( \Gamma \) with respect to \( \rho \) by \( G \) and its unipotent radical by \( U \). Denote their Lie algebras by \( g \) and \( u \). Since \( H_j(\Gamma, V) \) vanishes for all \( R \)-modules \( V \) for all \( j \geq 2 \), \( u \) is free. Consequently, (3.4) is an isomorphism in all degrees.

3.4.2. Modular groups. Suppose that \( \Gamma \) is a modular group — that is, a finite index subgroup of \( \text{SL}_2(\mathbb{Z}) \). Let \( R = \text{SL}_2 \) and \( \rho : \Gamma \to \text{SL}_2(\mathbb{Q}) \) be the inclusion. This has Zariski dense image. Denote the completion of \( \Gamma \) with respect to \( \rho \) by \( G \) and its unipotent radical by \( U \).

Every torsion free subgroup \( \Gamma' \) of \( \text{SL}_2(\mathbb{Z}) \) is the fundamental group of the quotient \( \Gamma' \backslash \mathfrak{h} \) of the upper half plane by \( \Gamma' \). Since this is a non-compact Riemann surface, \( \Gamma' \) is free. Since \( \text{SL}_2(\mathbb{Z}) \) has finite index torsion free subgroups (e.g., the matrices congruent to the identity mod \( m \) for any \( m \geq 3 \)), every modular group is virtually free. This implies that \( H^j(\Gamma, V) = 0 \) whenever \( j \geq 2 \) and \( V \) is a rational vector space. The results of Section 3.2 imply that the Lie algebra \( u \) of \( U \) is a free pronilpotent Lie algebra. As in the case of a free group, this implies that (3.4) is an isomorphism in all degrees.

The set \( \mathring{R} \) of isomorphism classes of irreducible \( R \)-modules is \( \mathbb{N} \). The natural number \( n \) corresponds to the \( n \)th symmetric power \( S^n H \) of the defining representation \( H \) of \( \text{SL}_2 \). The results of Section 3.2 imply that there is a non-canonical isomorphism

\[
\mathfrak{u} \cong \mathbb{L} \left( \bigoplus_{n \geq 0} H^1(\Gamma, S^n H)^* \otimes S^n H \right) ^\wedge
\]

of pronilpotent Lie algebras in the category of \( \text{SL}_2 \) modules. (Cf. Remarks 3.9 and 7.2 in [17].) So we have a complete description of \( \mathcal{G} \) as a proalgebraic group:

\[
\mathcal{G} \cong \text{SL}_2 \ltimes \exp \mathfrak{u}.
\]

In Section 4 we give a method for writing down the natural homomorphism \( \Gamma \to \text{SL}_2(\mathbb{C}) \times \exp \mathfrak{u} \).

3.4.3. Unipotent completion of fundamental groups of punctured elliptic curves. Here \( E \) is a smooth elliptic curve and \( \Gamma = \pi_1(E', x) \) where \( E' = E - \{0\} \) and \( x \in E' \). In this case we take \( R \) to be trivial. The corresponding completion of \( \Gamma \) is the unipotent completion of \( \pi_1(E', x) \). Since \( H^2(E', \mathbb{Q}) = 0 \), the results of Section 3.2 imply that the Lie algebra \( \mathfrak{p} \) of the unipotent completion of \( \pi_1(E', x) \) is (non-canonically isomorphic to) the completion of the free Lie algebra generated by \( H_1(E, \mathbb{Q}) \):

\[
\mathfrak{p} \cong \mathbb{L}(H_1(E)) ^\wedge.
\]

This induces a canonical isomorphism \( \mathcal{G}_{\text{LCS}}^* \mathfrak{p} \cong \mathbb{L}(H_1(E)) \) of the associated graded Lie algebra of the lower central series (LCS) of \( \mathfrak{p} \) with the free Lie algebra generated by \( H_1(E) \).
3.5. **Naturality and Right exactness.** The following naturality property is easily proved using either the universal mapping property of relative completion or its the tannakian description.

**Proposition 3.5.** Suppose that \( \Gamma \) and \( \Gamma' \) are discrete groups and that \( R \) and \( R' \) are reductive \( F \)-groups. If one has a commutative diagram

\[
\begin{array}{c}
\Gamma' \xrightarrow{\rho'} R' \\
\downarrow \quad \downarrow \\
\Gamma \xrightarrow{\rho} R
\end{array}
\]

in which \( \rho \) and \( \rho' \) are Zariski dense, then one has a commutative diagram

\[
\begin{array}{c}
\Gamma' \xrightarrow{} \tilde{\Gamma}' \xrightarrow{} R' \\
\downarrow \quad \downarrow \quad \downarrow \\
\Gamma \xrightarrow{} \tilde{\Gamma} \xrightarrow{} R
\end{array}
\]

where \( \tilde{\Gamma} \) and \( \tilde{\Gamma}' \) denote the completions of \( \Gamma \) and \( \Gamma' \) with respect to \( \rho \) and \( \rho' \). \( \square \)

Relative completion is not, in general, an exact functor. However, it is right exact. The following is a special case of this right exactness. It can be proved using the universal mapping property of relative completion. (A similar argument can be found in [22, §4.5].)

**Proposition 3.6.** Suppose that \( \Gamma \), \( \Gamma' \) and \( \Gamma'' \) are discrete groups and that \( R \), \( R' \) and \( R'' \) are reductive \( F \)-groups. Suppose that one has a diagram

\[
\begin{array}{c}
1 \xrightarrow{} \Gamma' \xrightarrow{\rho'} \Gamma \xrightarrow{\rho} \Gamma'' \xrightarrow{} 1 \\
\downarrow \quad \downarrow \quad \downarrow \\
1 \xrightarrow{} R' \xrightarrow{\rho''} R \xrightarrow{\rho} R'' \xrightarrow{} 1
\end{array}
\]

with exact rows in which \( \rho \), \( \rho' \) and \( \rho'' \) are Zariski dense, then the corresponding diagram

\[
\begin{array}{c}
\tilde{G}' \xrightarrow{} \tilde{G} \xrightarrow{} \tilde{G}'' \xrightarrow{} 1 \\
\downarrow \quad \downarrow \quad \downarrow \\
\tilde{R}' \xrightarrow{} \tilde{R} \xrightarrow{} \tilde{R}'' \xrightarrow{} 1
\end{array}
\]

of relative completions has right exact top row. \( \square \)

**Example 3.7.** The moduli space of \( n \geq 1 \) pointed genus 1 curves will be denoted by \( \mathcal{M}_{1,n} \). It will be regarded as an orbifold. It is isomorphic to (and will be regarded as) the moduli space of elliptic curves \((E,0)\) with \( n-1 \) distinct labelled points \((x_1,\ldots,x_{n-1})\). The point of \( \mathcal{M}_{1,n} \) that corresponds to \((E,0,x_1,\ldots,x_{n-1})\) will be denoted by \([E,x_1,\ldots,x_{n-1}]\).

The fiber of the projection \( \mathcal{M}_{1,2} \to \mathcal{M}_{1,1} \) that takes \([E,x]\) to \([E]\) is \( E' := E - \{0\} \).

Fix a base points \( x_o = [E,x] \) of \( \mathcal{M}_{1,2} \) and \( t_o = [E] \in \mathcal{M}_{1,1} \). The (orbifold) fundamental group of \( \mathcal{M}_{1,2} \) is an extension

\[
1 \to \pi_1(E',x) \to \pi_1(\mathcal{M}_{1,2},x_o) \to \pi_1(\mathcal{M}_{1,1},t_o) \to 1.
\]
Denote the completion of $\pi_1(\mathcal{M}_{1,2}, x_o)$ with respect to the natural homomorphism to $\text{SL}(H_1(E)) \cong \text{SL}_2(\mathbb{Q})$ by $\tilde{G}$. Functoriality and right exactness of relative completion implies that we have an exact sequence

$$\pi_1(E', x)^\text{un} \to \tilde{G} \to G \to 1.$$ 

In this case, we can prove exactness on the left as well.

This is proved using the conjugation action of $\pi_1(\mathcal{M}_{1,2}, x_o)$ on $\pi_1(E', x)$. This induces an action of $\pi_1(\mathcal{M}_{1,2}, x_o)$ on the Lie algebra $p$ of $\pi_1(E', x)^\text{un}$. This action preserves the lower central series filtration of $p$ and therefore induces an action on $\text{Gr}^p_{\text{LCS}}$. This action is determined by its action on $H_1(E)$, and therefore factors through the homomorphism $\pi_1(\mathcal{M}_{1,2}, x_o) \to \text{SL}_2(\mathbb{Q})$. The universal mapping property of relative completion implies that this induces an action $\tilde{G} \to \text{Aut} p$ and the corresponding Lie algebra homomorphism $\tilde{g} \to \text{Der} p$. The composite $p \to \tilde{g} \to \text{Der} p$ is the homomorphism induced by the conjugation action of $\pi_1(E', x)^\text{un}$ on itself and is therefore the adjoint action. Since $p$ is free of rank $\geq 1$, it has trivial center, which implies that the adjoint action is faithful and that $p \to \tilde{g}$ is injective.

### 3.6. Hodge Theory

Suppose that $X$ is the complement of a normal crossings divisor in a compact Kähler manifold. Suppose that $F = \mathbb{Q}$ or $\mathbb{R}$ and that $V$ is a polarized variation of $F$-Hodge structure over $X$. Pick a base point $x_o \in X$.

Denote the fiber over $V$ over $x_o$ by $V_o$. The Zariski closure of the image of the monodromy representation

$$\rho : \pi_1(X, x_o) \to \text{Aut}(V_o)$$

is a reductive $F$-group. Denote it by $R$. Then one has the relative completion $\tilde{G}$ of $\pi_1(X, x_o)$ with respect to $\rho : \pi_1(X, x_o) \to R(F)$.

**Theorem 3.8 ([16]).** The coordinate ring $\mathcal{O}(\tilde{G})$ is a Hopf algebra in the category of Ind-mixed Hodge structures over $F$. It has the property that $W_{-1}\mathcal{O}(\tilde{G}) = 0$ and $W_0\mathcal{O}(\tilde{G}) = \mathcal{O}(R)$.

A slightly weaker version of the theorem is stated in terms of Lie algebras. Denote the prounipotent radical of $\tilde{G}$ by $\mathcal{U}$. Denote their Lie algebras by $\mathfrak{g}$ and $\mathfrak{u}$, and the Lie algebra of $R$ by $\mathfrak{r}$.

**Corollary 3.9 ([16]).** The Lie algebra $\mathfrak{g}$ is a Lie algebra in the category of pro-mixed Hodge structures over $F$. It has the property that

$$\mathfrak{g} = W_0\mathfrak{g}, \quad \mathfrak{u} = W_{-1}\mathfrak{g}, \quad \text{and} \quad \text{Gr}^W_0 \mathfrak{g} \cong \mathfrak{r}.$$ 

If $V$ is a PVHS over $X$ with fiber $V_o$ over the base point $x_o$, then the composite

$$H^\ast(\mathfrak{g}, V_o)^{\pi_0(R)} \to H^\ast(\Gamma, V_o) \to H^\ast(X, V)$$

of (3.3) with the canonical homomorphism is a morphism of MHS. It is an isomorphism in degrees $\leq 1$ and injective in degree 2. When $X$ is an (orbi) curve, it is an isomorphism in all degrees.

The existence of the mixed Hodge structure on $u$ in the unipotent case and when $X$ is not necessarily compact is due to Morgan [34] and Hain [16]. The results in this section also hold in the orbifold case.

---

3We also allow tangential base points.
Example 3.10. The local system $R^1f_*\mathbb{Q}$ over $\mathcal{M}_{1,1}$ associated to the universal elliptic curve $f : \mathcal{E} \to \mathcal{M}_{1,1}$ is a polarized variation of Hodge structure. This variation and its pullback to $\mathcal{M}_{1,n}$ will be denoted by $\mathbb{H}$. It has fiber $H_1(E)$ over $[E]$. The Zariski closure of the monodromy representation $\pi_1(\mathcal{M}_{1,1}, [E]) \to \text{Aut} H_1(E)$ is $\text{SL}(H_1(E))$, which is isomorphic to $\text{SL}_2$.

The choice of an elliptic curve $E$ and a non-zero point $x$ of $E$ determines compatible base points of $\mathcal{E}'$, $\mathcal{M}_{1,1}$ and $\mathcal{M}_{1,2}$.

Denote the Lie algebras of the relative completions of $\pi_1(\mathcal{M}_{1,1}, [E])$ and $\pi_1(\mathcal{M}_{1,2}, [E, x])$ by $\mathfrak{g}$ and $\tilde{\mathfrak{g}}$, respectively. Denote the Lie algebra of the unipotent completion of $\pi_1(\mathcal{E}', x)$ by $\mathfrak{p}$. The results of this section imply that each has a natural MHS and that the sequence

$$0 \to \mathfrak{p} \to \tilde{\mathfrak{g}} \to \mathfrak{g} \to 0$$

is exact in the category of MHS. The adjoint action of $\tilde{\mathfrak{g}}$ on $\mathfrak{p}$ induces an action

$$\tilde{\mathfrak{g}} \to \text{Der} \mathfrak{p}$$

Since the inclusion $\mathfrak{p} \to \tilde{\mathfrak{g}}$ is a morphism of MHS, this homomorphism is a morphism of MHS.

Since the functor $\text{Gr}^W$ is exact on the category of MHS, one can study this action by passing to its associated graded action

$$\text{Gr}^W \tilde{\mathfrak{g}} \to \text{Der} \mathfrak{L}(H_1(E)).$$

4. A Concrete Approach to Relative Completion

Suppose that $M$ is the orbifold quotient $\Gamma \backslash X$ of a simply connected manifold $X$ by a discrete group $\Gamma$. We suppose that $\Gamma$ acts properly discontinuously and virtually freely on $X$. Our main example will be when $X = \mathfrak{h}$ and $\Gamma$ is a finite index subgroup of $\text{SL}_2(\mathbb{Z})$.

Suppose that $R$ is a complex (or real) Lie group and that $(u_\alpha)_\alpha$ is an inverse system of finite dimensional nilpotent Lie algebras in the category of $R$-modules. Its limit

$$\mathfrak{u} = \varprojlim u_\alpha$$

is a pronilpotent Lie algebra in the category of $R$-modules. Denote the unipotent Lie group corresponding to $u_\alpha$ by $U_\alpha$. The pronilpotent Lie group corresponding to $\mathfrak{u}$ is the inverse limit of the $U_\alpha$.

The action of $R$ on $\mathfrak{u}$ induces an action of $R$ on $\mathcal{U}$, so we can form the semi-direct product $R \rtimes \mathcal{U}$. This is the inverse limit

$$R \rtimes \mathcal{U} = \varprojlim (R \rtimes U_\alpha)$$

If $R$ is an algebraic group, then $R \rtimes \mathcal{U}$ is a proalgebraic group.

Suppose that $\rho : \Gamma \to R$ is a representation. At this stage, we do not assume that $\rho$ has Zariski dense image. The following assertion is easily proved.

\[\text{For a detailed and elementary description of what this means, see [20, §3].}\]

\[\text{That is, $\Gamma$ has a finite index subgroup that acts freely on $X$.}\]

\[\text{To be clear, the group $R \rtimes \mathcal{U}$ is the set $U \times R$ with multiplication} \]

$$(u_1, r_1)(u_2, r_2) = (u_1(r_1 \cdot u_2), r_1 r_2),$$

where $r \cdot u$ denotes the action of $R$ on $U$. We will omit the dot when it is clear from the context that $ru$ means the action of $R$ on $U$.\]
Lemma 4.1. Homomorphisms $\hat{\rho} : \Gamma \rightarrow R \ltimes U$ that lift $\rho$ correspond to functions $F : \Gamma \rightarrow U$ that satisfy the 1-cocycle condition

$$F(\gamma_1 \gamma_2) = F(\gamma_1)(\gamma_1 \cdot F(\gamma_2)).$$

The homomorphism $\hat{\rho}$ corresponds to the function $\Gamma \rightarrow U \times R \gamma \mapsto (F(\gamma), \rho(\gamma))$ under the identification of $R \ltimes U$ with $U \times R$. □

Cocycles can be constructed from $\Gamma$-invariant 1-forms on $X$ with values in $u$. Define

$$E^\bullet(X) \hat{\otimes} u := \lim_{\leftarrow} E^\bullet(X) \otimes u_\alpha,$$

where $E^\bullet(X)$ denotes the complex of smooth $\mathbb{C}$-valued forms on $X$. The group $\Gamma$ acts on $E^\bullet(X) \hat{\otimes} u$ by

$$\gamma \cdot \omega = ((\gamma^*)^{-1} \otimes \gamma)\omega.$$

Such a form $\omega$ is invariant if

$$(\gamma^* \otimes 1)\omega = (1 \otimes \gamma)\omega$$

for all $\gamma \in \Gamma$.

Let $\Gamma$ act on $X \times U$ diagonally: $\gamma : (u, x) \mapsto (\gamma u, \gamma x)$. The projection

$$X \times U \rightarrow X$$

is a $\Gamma$-equivariant principal $U$-bundle. Its sections correspond to functions $f : X \rightarrow U$. Each $\omega \in E^1(X) \hat{\otimes} u$ defines a connection on this bundle via the formula

$$\nabla f = df + \omega f.$$

where $f$ is a $U$-valued function defined locally on $X$. The connection is $\Gamma$-invariant if and only if $\omega$ is $\Gamma$-invariant. It is flat if and only if $\omega$ is integrable:

$$d\omega + \frac{1}{2} [\omega, \omega] = 0 \quad \text{in} \ E^2(X) \hat{\otimes} u.$$

In this case, parallel transport defines a function

$$T : PX \rightarrow U$$

from the path space of $X$ into $U$. With our conventions, this satisfies $T(\alpha \ast \beta) = T(\beta)T(\alpha)$. When $\omega$ is integrable, $T(\alpha)$ depends only on the homotopy class of $\gamma$ relative to its endpoints. Chen’s transport formula implies that the inverse transport function is given by the formula

$$(4.2) \quad T(\alpha)^{-1} = 1 + \int_{\alpha} \omega + \int_{\alpha} \omega \omega + \int_{\alpha} \omega \omega \omega + \cdots$$

Cf. [21, Cor. 5.6].

Fix a point $x_0 \in X$. Since $X$ is simply connected, for each $\gamma \in \Gamma$ there is a unique homotopy class $c_\gamma$ of paths from $x_0$ to $\gamma \cdot x_0$.

Proposition 4.3. If $\omega \in E^1(X) \hat{\otimes} u$ is $\Gamma$-invariant and integrable, then the function $\Theta_x : \Gamma \rightarrow U$ defined by

$$\Theta_x(\gamma) = T(c_\gamma)^{-1}$$

is a well-defined 1-cocycle with values in $U$:

$$\Theta_x(\gamma \mu) = \Theta_x(\gamma)(\gamma \cdot \Theta_x(\mu)).$$
Consequently, the function \( \tilde{\rho}_{x_0} : \Gamma \rightarrow R \ltimes U \) defined by \( \gamma \mapsto (\Theta_{x_0}(\gamma), \rho(\gamma)) \) is a homomorphism.

**Proof.** This follows directly from the fact that
\[
c_{\gamma \mu} = c_{\gamma \ast (\rho(\gamma) \cdot c_{\mu})}
\]
and the transport formula above. \( \square \)

**Remark 4.4.** The dependence of \( \Theta_{x_0} \) and \( \tilde{\rho}_{x_0} \) on \( x_0 \) is easily determined. Suppose that \( x' \) is a second base point. If \( e \) is the unique homotopy class of paths in \( X \) from \( x_0 \) to \( x' \), then \( c'_{\gamma} := e^{-1} \ast c_{\gamma \ast (\gamma \cdot e)} \) is the unique homotopy class of paths in \( X \) from \( x' \) to \( \gamma \cdot x' \). Thus
\[
T(c'_{\gamma})^{-1} = T(e)T(c_{\gamma})^{-1}(\gamma \cdot T(e)^{-1}).
\]
Since, for \( u, v \in U \) and \( r \in R \),
\[
(v, 1)(u, r)(v^{-1}, 1) = (v(r \cdot v^{-1}), \gamma)
\]
in \( R \ltimes U \), the previous formula implies that \( \tilde{\rho}_{x'} \) is obtained from \( \tilde{\rho}_{x_0} \) by conjugation by \( T(e) \in U \) and that
\[
\Theta_{x'}(\gamma) = T(e)\Theta_{x_0}(\gamma \cdot T(e)^{-1}).
\]

**4.1. Variant.** Later we will need to use a more general setup. In much of the paper we use the setup of the previous section, but occasionally it will be convenient to work in this more general setup. This material is standard. More details can be found in [21, §5].

Recall that a **factor of automorphy** is a smooth function
\[
M : \Gamma \times X \rightarrow R, \quad (\gamma, x) \mapsto M_\gamma(x)
\]
that satisfies \( M_{\gamma \mu}(x) = M_\gamma(\mu x)M_\mu(x) \) for all \( x \in X \) and \( \gamma, \mu \in \Gamma \). One checks easily that the function
\[
\gamma : (x, u) \mapsto (\gamma x, M_\gamma(x)u)
\]
defines an action of \( \Gamma \) on \( X \times U \).

Suppose that \( \nabla_0 \) is a connection on the \( R \)-bundle \( X \times U \rightarrow X \). A 1-form \( \omega \in E^1(X) \otimes u \) defines a connection \( \nabla \) on this bundle by
\[
\nabla f = \nabla_0 f + \omega f,
\]
where \( f : X \rightarrow U \) is a section. This connection is \( \Gamma \)-invariant if and only if
\[
(\gamma^* \otimes 1)\omega = (1 \otimes M_\gamma)\omega - dM_\gamma M_\gamma^{-1}.
\]
and flat if and only if \( d\omega + [\omega, \omega]/2 = 0 \).
When $\nabla$ is a flat $\Gamma$-invariant connection, the monodromy representation
\[ \Theta_{x_{\alpha}} : \Gamma \to R \ltimes U \]
is given by
\[ \Theta_{x_{\alpha}} : \gamma \mapsto (T(c_{\gamma})^{-1}, M_{\gamma}(x_{\alpha})) \]
where for a path $\alpha \in X$, $T(\alpha)$ is given by the formula (4.2).

The setup of the previous section is a special case where $M_{\gamma}(x) = \rho(\gamma)$ and where the connection $\nabla_0$ is trivial; that is, $\nabla_0 = d$.

4.2. A characterization of relative unipotent completion. To give a concrete construction of the completion of $\Gamma$ relative to $\rho : \Gamma \to R$, we need a useful criterion for when a homomorphism $\Gamma \to R \ltimes U$ is the relative completion. In the present situation, the criterion is cohomological.

Suppose that $\omega \in E^1(X) \otimes u$ is an integrable, $\Gamma$-invariant 1-form on $X$, as above. Suppose that $V$ is a finite dimensional $R$-module. Then $\Gamma$ acts on $X \times V$ diagonally. The formula
\[ \nabla v = dv + \omega \cdot v \]
defines a flat $\Gamma$-invariant connection on the vector bundle $X \times V \to X$. The complex
\[ (E^\bullet(X) \otimes V)^\Gamma := \{ \omega \in E^\bullet(X) \otimes V : (\gamma^* \otimes 1)\omega = (1 \otimes \gamma)\omega \} \]
of $\Gamma$-invariant $V$-valued forms on $X$ has differential defined by
\[ \nabla(\eta \otimes v) = d\eta \otimes v + \eta \wedge (\omega \cdot v), \]
where $\eta \in E^\bullet(X)$ and $v \in V$. It computes the cohomology $H^\bullet(M, V)$ of the orbifold $M$ with coefficients in the orbifold local system $V$ of locally constant sections of the flat vector bundle $\Gamma \backslash (X \times V)$ over $M$.

**Lemma 4.5.** If $R$ is reductive, each integrable $\Gamma$-invariant 1-form $\omega \in E^1(X) \otimes u$ induces a ring homomorphism
\[ H^\bullet(u, V)^R \to H^\bullet(M, V). \]

**Proof.** A 1-form $\omega \in E^1(X) \otimes u$ can be regarded as a function
\[ \theta_\omega : \text{Hom}^{cts}(u, \mathbb{C}) \to E^1(X), \quad \varphi \mapsto (1 \otimes \varphi)\omega. \]
It is $\Gamma$-equivariant if and only if $\omega$ is. The induced algebra homomorphism
\[ C^\bullet(u) = \Lambda^\bullet \text{Hom}^{cts}(u, \mathbb{C}) \to E^\bullet(X) \]
commutes with differentials if and only if $\omega$ is integrable. So a $\Gamma$-invariant and integrable 1-form $\omega \in E^1(X) \otimes u$ induces a dga homomorphism
\[ C^\bullet(u, V)^R = [(\Lambda^\bullet \text{Hom}^{cts}(u, \mathbb{C})) \otimes V]^R \to (E^\bullet(X) \otimes V)^\Gamma. \]
Since $R$ is reductive, the natural map
\[ H^\bullet(C^\bullet(u, V)^R) \to H^\bullet(C^\bullet(u, V))^R \]
is an isomorphism. The result follows. □

The desired characterization of relative completion is:
Proposition 4.6. If \( R \) is reductive and \( \rho : \Gamma \to R \) has Zariski dense image, then the homomorphism \( \tilde{\rho}_\omega : \Gamma \to R \rtimes U \) constructed from \( \omega \in (E^1(X) \otimes u)^\Gamma \) above is the completion of \( \Gamma \) with respect to \( \rho \) if and only if the homomorphism
\[
\theta_\omega^* : [H^j(u) \otimes V]^R \to H^j(M, V)
\]
induced by \( \theta_\omega \) is an isomorphism when \( j = 0, 1 \) and injective when \( j = 2 \).

Such universal 1-forms can be constructed using a suitable modification of Chen’s method of power series connections [7].

Proof. Denote the completion of \( \Gamma \) relative to \( \rho \) by \( G \). The universal mapping property of relative completion implies that the homomorphism \( \tilde{\rho}_\omega : \Gamma \to R \rtimes U \) induces a homomorphism \( \Psi : G \to R \rtimes U \) that commutes with the projections to \( R \). Denote the prounipotent radical of \( G \) by \( V \). Then \( \Psi \) induces a homomorphism \( V \to U \) and an \( R \)-invariant homomorphism \( \Psi^* : H^\bullet(u) \to H^\bullet(n) \) on the cohomology of their Lie algebras. Then for each finite dimensional \( R \)-module \( V \), one has the commutative diagram
\[
\begin{array}{ccc}
[H^\bullet(n) \otimes V]^R & \longrightarrow & H^\bullet(\Gamma, V) \\
\downarrow \phi & & \downarrow \\
[H^\bullet(u) \otimes V]^R & \longrightarrow & H^\bullet(M, V)
\end{array}
\]
where the right-hand vertical mapping is induced by the orbifold morphism \( M \to B\Gamma / M \) into the classifying space of \( \Gamma \). Standard topology implies that this is an isomorphism in degrees 0 and 1 and injective in degree 2. Results in Section 3.2 imply that the top row is an isomorphism in degrees 0 and 1, and injective in degree 2. The assumption implies that the left hand vertical map is an isomorphism in degrees 0 and 1 and injective in degree 2. Since \( H^\bullet(u) \) and \( H^\bullet(n) \) are direct limits of finite dimensional \( R \)-modules, by letting \( V \) run through all finite dimensional irreducible \( R \)-modules, we see that \( H^\bullet(n) \to H^\bullet(u) \) is an isomorphism in degrees 0 and 1 and and injective in degree 2. Proposition 2.1 implies that \( u \to n \) is an isomorphism. This implies that \( \Psi \) is an isomorphism.

\[\square\]

4.3. Rational structure. To construct a MHS on the completion of (say) a modular group \( \Gamma \), we will first construct its complex form together with its Hodge and weight filtrations using an integrable, \( \Gamma \)-invariant 1-form, as above. An easy formal argument, given below, implies that this relative completion has a natural \( \mathbb{Q} \)-structure provided that \( R \) and \( \rho \) are defined over \( \mathbb{Q} \). But to understand the MHS — for example, to be able to compute extension data — we will need a concrete description of the \( \mathbb{Q} \)-structure on \( R \rtimes U \) in terms of periods. Explaining this is the task of this section.

In general, we are not distinguishing between a proalgebraic \( F \)-group and its group of \( F \) rational points. Here, since we are discussing Hodge theory, we will distinguish between a \( \mathbb{Q} \)-group, and its groups of \( \mathbb{Q} \) and \( \mathbb{C} \) rational points.

Suppose that \( R \) is a reductive group that is defined over \( \mathbb{Q} \) and that \( \rho : \Gamma \to R \) takes values in the \( \mathbb{Q} \)-rational points \( R(\mathbb{Q}) \) of \( R \). Denote the completion of \( \Gamma \) with respect to \( \rho \) over \( \mathbb{Q} \) by \( \mathcal{G} \) and its prounipotent radical by \( N \). These are proalgebraic \( \mathbb{Q} \)-groups. We also have the completion \( \mathcal{G}_\mathbb{C} \) of \( \Gamma \) over \( \mathbb{C} \) relative to
\(\rho\), where the coefficient field is \(\mathbb{C}\). Base change (cf. Section 3.3) implies that the natural homomorphism \(G \otimes \mathbb{Q} \mathbb{C} \to \mathcal{G}_C\) is an isomorphism.

When the hypotheses of Proposition 4.6 are satisfied we obtain a canonical \(\mathbb{Q}\)-structure on \(R \ltimes U\) from the isomorphism
\[
\psi : \mathcal{G} \otimes \mathbb{Q} \mathbb{C} \cong R \ltimes U.
\]
induced by \(\hat{\rho}_{x_o}\). The \(\mathbb{Q}\)-structure on \(U\) is the image of the restriction \(N \otimes \mathbb{Q} \mathbb{C} \to U\) of this isomorphism to \(\mathcal{N}\). This induces a canonical \(\mathbb{Q}\)-structures on \(u\) via the isomorphism \(u \cong n \otimes \mathbb{Q} \mathbb{C}\).

**Proposition 4.7.** The canonical \(\mathbb{Q}\)-structure on \(u\) is the \(\mathbb{Q}\)-Lie subalgebra of \(u\) generated by the set \(\{\log \Theta_{x_o}(\gamma) : \gamma \in \Gamma\}\).

**Proof.** Fix a splitting \(s\) of the surjection \(G \to R_Q\). This gives an identification of \(G\) with \(R_Q \ltimes \mathcal{N}\). Levi’s Theorem (Prop. 3.1) implies that there is a \(u \in U\) such that the composition of
\[
R_Q \xrightarrow{s} G \xrightarrow{\psi} R \ltimes U
\]
is conjugate to the section \(R_Q \to R \ltimes U\) that takes \(r\) to \((1, r)\). That is, the first section takes \(r \in R\) to \((u(r \cdot u)^{-1}, r) \in R \ltimes U\). The composite
\[
R_Q \ltimes \mathcal{N} \xrightarrow{\psi} G \xrightarrow{\psi} R \ltimes U
\]
is thus given by the formula
\[
(4.8) \quad (n, r) \mapsto (\psi(n), 1)(u(r \cdot u)^{-1}, r) = (\psi(n)u(r \cdot u)^{-1}, r) \in R \ltimes U.
\]

The composite
\[
\Gamma \xrightarrow{s} G(\mathbb{Q}) \xrightarrow{\psi} R(\mathbb{Q}) \ltimes \mathcal{N}(\mathbb{Q})
\]
takes \(\gamma \in \Gamma\) to \((F(\gamma), \gamma) \in \mathcal{N}(\mathbb{Q}) \times R(\mathbb{Q})\) for some \(1\)-cocycle \(F : \Gamma \to \mathcal{N}(\mathbb{Q})\). Note that every divisible subgroup of the rational points of a prounipotent \(\mathbb{Q}\)-group \(N\) is the set of \(\mathbb{Q}\)-rational points of a \(\mathbb{Q}\)-subgroup of \(N\). This implies that the smallest subgroup of \(\mathcal{N}(\mathbb{Q})\) that contains \(\{F(\gamma) : \gamma \in \Gamma\}\) is the set of \(\mathbb{Q}\)-points of a \(\mathbb{Q}\)-subgroup \(S\) of \(\mathcal{N}\). The subgroup \(S\) must be \(\mathcal{N}\). This is because the cocycle condition implies that it is a \(\Gamma\)-invariant subgroup:
\[
\gamma_1 \cdot F(\gamma_2) = F(\gamma_1)^{-1}F(\gamma_1 \gamma_2) \in S(\mathbb{Q}).
\]
Since \(\Gamma\) is Zariski dense in \(G, S\) is a normal subgroup of \(G\). This implies that \(R_Q \ltimes S\) is a subgroup of \(G = R_Q \ltimes \mathcal{N}\) that contains the image of the canonical homomorphism \(\hat{\rho} : \Gamma \to \mathcal{G}(\mathbb{Q})\). But since \(\hat{\rho}\) is Zariski dense, we must have \(\mathcal{G} = R_Q \ltimes S\).

Formula (4.8) now implies that the image of \(\mathcal{N}(\mathbb{Q})\) in \(U(\mathbb{C})\) is the smallest divisible subgroup of \(U(\mathbb{C})\) that contains the set \(\{\psi \circ F(\gamma) : \gamma \in \Gamma\}\). But the formula (4.8) and the commutativity of the diagram
\[
\begin{array}{ccc}
\Gamma & \xrightarrow{s} & G(\mathbb{Q}) \\
\downarrow & & \downarrow \psi \\
R \ltimes U \\
\end{array}
\]
imply that \(\psi \circ F = \Theta_{x_o}\), so that the the image of \(\mathcal{N}(\mathbb{Q})\) in \(U\) is the smallest divisible subgroup of \(U\) that contains the set \(\{\Theta_{x_o}(\gamma) : \gamma \in \Gamma\}\). The result now follows from the Baker-Campbell-Hausdorff formula. \(\square\)
Remark 4.9. One might think that this \( \mathbb{Q} \) structure can be constructed as the image of the unipotent completion over \( \mathbb{Q} \) of \( \ker \rho \) in \( \mathcal{U} \). This often works, but it does not when \( \Gamma \) is a modular group as \( \rho : \Gamma \to \mathcal{R} \) is injective and \( \mathcal{U} \) is non-trivial in this case.

4.3.1. Complements. The coordinate ring \( \mathcal{O}(\mathcal{G}) \) of \( \mathcal{G} \) is isomorphic, as a ring, to \( \mathcal{O}(\mathcal{R}) \otimes \mathcal{O}(\mathcal{U}) \). Its coproduct is twisted by the action of \( \mathcal{R} \) on \( \mathcal{U} \). The \( \mathbb{Q} \)-form of \( \mathcal{O}(\mathcal{G}) \) consists of those elements of \( \mathcal{O}(\mathcal{R}) \otimes \mathcal{O}(\mathcal{U}) \) that rational values on the image of \( \Gamma \to R \ltimes \mathcal{U} \). Since the exponential map \( u \to \mathcal{U} \) is an isomorphism of proaffine varieties, the coordinate ring of \( \mathcal{U} \) consists of the polynomial functions on \( u \). Since the coefficients of the logarithm and exponential functions are rational numbers, \( \mathcal{O}(\mathcal{U}_{\mathbb{Q}}) \) is the ring of polynomials on \( u_{\mathbb{Q}} \) that are continuous functions \( u_{\mathbb{Q}} \to \mathbb{Q} \).

5. Relative Completion of Path Torsors

This section can be omitted on a first reading. Here we consider the relative completion \( \mathcal{G}_{x,y} \) of the torsor of paths from \( x \) to \( y \) in a manifold \( M \) with respect to a reductive local system \( \mathcal{H} \). This can be described using tannakian formalism.\(^7\)

Here we outline a direct approach partly because it is more concrete and better suits our needs.

We use the setup of the previous section. So \( M = \Gamma \backslash X \) where \( X \) is a simply connected manifold, \( \Gamma \) is a discrete group that acts properly discontinuously and virtually freely on \( X \) and \( \rho : \Gamma \to \mathcal{R} \) is a representation of \( \Gamma \) into an affine \( F \)-group \( (F = \mathbb{R} \) or \( \mathbb{C} \)) not yet assumed to be reductive or Zariski dense.

If \( M \) is a manifold and \( x, y \in M \), then \( \Pi(M; x, y) \) denotes the set of homotopy classes of paths from \( x \) to \( y \). We need to define what we mean by \( \Pi(M; x, y) \) when the action of \( \Gamma \) is not free, in which case, \( M \) is an orbifold, but not a manifold. We will use the concrete approach of [20].

Choose a fundamental domain \( D \) for the action of \( \Gamma \) on \( X \). A point \( x \) of \( M \) is a \( \Gamma \)-orbit of points in \( X \). This orbit contains a unique point \( \tilde{x} \in D \). Suppose that \( x, y \in M \). Elements of \( \Pi(M; x, y) \) are pairs \( (\gamma, c_\gamma) \), where \( \gamma \in \Gamma \) and \( c_\gamma \) is a homotopy class of paths from \( \tilde{x} \) to \( \gamma \tilde{y} \). (This homotopy class is unique as \( X \) is simply connected.) Define the composition

\[
\Pi(M; x, y) \times \Pi(M; y, z) \to \Pi(M; x, z)
\]

by

\[
((\gamma, c_\gamma), (\mu, c_\mu)) \mapsto (\gamma\mu, c_{\gamma\mu}) := (\gamma\mu, c_\gamma * (\gamma \cdot c_\mu)).
\]

Note that \( \Pi(M; x, y) \) is a torsor under the left action of \( \pi_1(M, x) := \Pi(M, x, x) \) and a torsor under the right action of \( \pi_1(M, y) \).

This definition of \( \Pi(M; x, y) \) agrees with the standard definition when the action of \( \Gamma \) is fixed point free.

Now suppose that \( F \) is \( \mathbb{R} \) or \( \mathbb{C} \), \( H \) is a finite dimensional vector space over \( F \), \( R \) is a reductive subgroup of \( \text{GL}(H) \), and \( \rho : \Gamma \to R(F) = R \) is a Zariski dense representation. Let \( \mathcal{H} \) be the corresponding (orbifold) local system over the orbifold \( M \).

\(^7\)The category of local systems of finite dimensional \( F \)-vector spaces over \( M \) that admit a filtration whose graded quotients are subquotients of tensor powers of \( \mathcal{H} \) is tannakian. The completion \( \mathcal{G}_{x,y} \) of the torsor \( \Pi(M; x, y) \) of paths in \( M \) from \( x \) to \( y \) is the torsor of isomorphisms between the fiber functors at \( x \) and \( y \). It is an affine scheme over \( F \).
As in the previous section, we suppose that \( \omega \in E^1(X) \hat{\otimes} u \) is an integrable, \( \Gamma \)-invariant 1-form on \( X \). Define
\[
\Theta_{x,y} : \Pi(M; x, y) \to R \times U \text{ by } (\gamma, c^\gamma) \mapsto (\rho(\gamma), T(c^\gamma)^{-1}).
\]
Note that, unless \( x = y \), this is not a group homomorphism. The universal mapping property of \( G_{x,y} \) implies that \( \Theta_{x,y} \) induces a morphism \( G_{x,y} \to R \times U \) such that the diagram
\[
P\pi_0 \longrightarrow \mathcal{G}_{x,y} \quad \quad \quad \quad G_{x,y} \rangle \quad \longrightarrow \quad R \times U
\]
of affine schemes. If \( \omega \) satisfies the assumptions of Proposition 4.6, then the vertical morphism is an isomorphism. This follows as, in this case, \( G_{x,y} \) and \( R \times U \) are both torsors under the left action of the relative completion \( G_{x,x} \cong R \times U \) of \( \Gamma \cong \pi_1(M, x) \) with respect to \( \rho \).

If \( R \) and \( \rho \) are defined over \( \mathbb{Q} \), then \( \mathcal{G}_{x,y} \) has a natural \( \mathbb{Q} \) structure consisting of those elements of \( O(\mathcal{G}_{x,y}) \) that take rational values on the image of \( \Pi(M; x, y) \) in \( \mathcal{G}_{x,y} \).

6. Zucker’s Mixed Hodge Complex

In this section we recall the construction of the natural MHS on the cohomology of a smooth curve with coefficients in a polarized variation of Hodge structure.

Suppose that \( C \) is a compact Riemann surface and that \( D \) is a finite subset, which we assume to be non-empty. Then \( C' := C - D \) is a smooth affine curve. Suppose that \( V \) is a polarized variation of Hodge structure over \( C' \) of weight \( m \). For simplicity, we assume that the local monodromy about each \( x \in D \) is unipotent. Zucker \([48, \S 13]\) constructs a cohomological Hodge complex \( K(V) \) that computes the MHS on \( H^*(C', V) \). In this section we recall the definition of its complex component \( K_C(V) \), together with its Hodge and weight filtrations. We first recall a few basic facts about mixed Hodge complexes.

6.1. Review of mixed Hodge complexes. This is a very brief outline of how one constructs a mixed Hodge structure on a graded vector space using a mixed Hodge complex. Full details can be found in [11].

The standard method for constructing a mixed Hodge structure on a graded invariant \( M^\bullet \) of a complex algebraic variety is to express the invariant as the cohomology of a mixed Hodge complex (MHC). Very briefly, a MHC \( K \) consists of:

(i) two complexes \( K_Q^\bullet \) and \( K_C^\bullet \), each endowed with a weight filtration \( W_\bullet \) by subcomplexes,

(ii) a \( W_\bullet \) filtered quasi-isomorphism between \( K_Q \otimes \mathbb{C} \) and \( K_C \).

(iii) a Hodge filtration \( F^\bullet \) of \( K_C^\bullet \) by subcomplexes.

These are required to satisfy several technical conditions, which we shall omit, although the lemma below encodes some of them. The complexes \( K_Q^\bullet \) and \( K_C^\bullet \) compute the \( \mathbb{Q} \)- and \( \mathbb{C} \)-forms of the invariant \( M^\bullet \):
\[
M_Q^\bullet \cong H^*(K_Q^\bullet) \text{ and } M_C^\bullet \cong H^*(K_C^\bullet).}
\]
The quasi-isomorphism between them is compatible with these isomorphisms. The weight filtration of $K^\bullet_Q$ induces a weight filtration of $M_Q$ by

$$W_m M^j_Q = \text{im}\{W_{m-j}H^j(K^\bullet_Q) \rightarrow M^j_Q\}.$$  

The assumption that the quasi-isomorphism between $K^\bullet_Q \otimes \mathbb{C}$ and $K^\bullet_C$ be $W_\bullet$-filtered implies that the weight filtrations of $K^\bullet_Q$ and $K^\bullet_C$ induce the same weight filtration on $M^\bullet$. That is,

$$(W_m M^j_Q \otimes \mathbb{C}) = \text{im}\{W_{m-j}H^j(K^\bullet_C) \rightarrow M^j_C\}$$

Finally, the Hodge filtration of $K^\bullet_C$ induces the Hodge filtration of $M^\bullet_C$ via

$$F^p M^\bullet_C := \text{im}\{H^\bullet(F^p K^\bullet_C) \rightarrow M^\bullet_C\}.$$  

If $K$ is a MHC, then $M^\bullet$ is a MHS with these Hodge and weight filtrations.

We shall need the following technical statement. As pointed out above, this is equivalent to several of the technical conditions satisfied by a MHC.

**Lemma 6.1** ([15, 3.2.8]). Suppose that $(K^\bullet_C, W_\bullet, F^\bullet)$ is the complex part of a MHC. If $u \in F^p W_m K^j_C$ is exact in $K^\bullet_C$, then there exists $v \in F^p W_{m+1} K^{j-1}_C$ such that $dv = u$.

Finally, a **cohomological mixed Hodge complex** (CMHC) is a collection of filtered complexes of sheaves on a variety (or a topological space) with the property that the global sections of a collection of acyclic resolutions of its components is a MHC. For details, see [11].

### 6.2. Zucker’s cohomological MHC.

We’ll denote Zucker’s cohomological MHC for computing the MHS on $H^\bullet(C', \mathcal{V})$ by $K(\mathcal{V})$. We describe only its complex part $K^\bullet_C(\mathcal{V})$.

Set $\mathcal{V} = \mathcal{V} \otimes \mathcal{O}_{C'}$. This has a canonical connection $\nabla$. This extends to a meromorphic connection

$$\nabla : \nabla \rightarrow \Omega_C^1(\log D) \otimes \nabla$$

on Deligne’s canonical extension $\nabla$ of it to $C$. The Hodge sub-bundles of $\mathcal{V}$ extend to holomorphic sub-bundles $F^p \nabla$ of $\nabla$.

As a sheaf, $K^\bullet_C(\mathcal{V})$ is simply $\Omega^\bullet_C(\log D) \otimes \nabla$ with the differential $\nabla$. Standard arguments imply that $H^\bullet(C, K^\bullet_C(\mathcal{V}))$ is isomorphic to $H^\bullet(C', \mathcal{V})$. Its Hodge filtration is defined in the obvious way:

$$F^p K^\bullet_C(\mathcal{V}) := \sum_{s+t=p} (F^s \Omega'^\bullet_C(\log D)) \otimes F^t \nabla.$$

In degree 0 the weight filtration is simply

$$0 = W_{m-1} K^\bullet_C(\mathcal{V}) \subseteq W_m K^\bullet_C(\mathcal{V}) = K^\bullet_C(\mathcal{V}).$$

In degree 1, $W_r K^\bullet_C(\mathcal{V})$ vanishes when $r < m$. To define the remaining terms in degree 1, consider the residue mapping

$$\text{Res}_P : \Omega^1_C(\log D) \otimes \nabla \rightarrow V_P,$$

which takes values in the fiber $V_P$ of $\nabla$ over $P$. The residue $N_P$ of the connection $\nabla$ on $\nabla$ at $P \in C$ is the local monodromy logarithm divided by $2\pi i$. It acts on $V_P$. When $r \geq 0$, the stalk of $W_{m+r} K^\bullet_C(\mathcal{V})$ at $P$ is

$$W_{m+r} K^\bullet_C(\mathcal{V})_P := \text{Res}^{-1}_P (\text{im} N_P + \ker N^r_P).$$
Note that, when $P \notin D$, the residue map vanishes (and so does $N_P$), so that the stalk of $W_mK_C(\mathcal{V})$ when $P \notin D$ is $K_C(\mathcal{V})_P$.

The Hodge and weight filtrations on $H^j(C',\mathcal{V})$ are defined by

$$F^pH^j(C',\mathcal{V}) = \text{im}\{H^j(C,F^pK_C(\mathcal{V})) \to H^j(C',\mathcal{V})\}$$

and

$$W_mH^j(C',\mathcal{V}) = \text{im}\{H^j(C,W_{m-j}K_C(\mathcal{V})) \to H^j(C',\mathcal{V})\}.$$  

The definition of the weight filtration implies that $H^0(C'\mathcal{V})$ has weight $m$ and that the weights on $H^1(C',\mathcal{V})$ are $\geq 1 + m$.

**Remark 6.2.** Let $j : C' \to C$ denote the inclusion. The complex of sheaves $W_mK_C(\mathcal{V})$ on $C$ is a cohomological Hodge complex that is easily seen to be quasi-isomorphic to the sheaf $j_*\mathcal{V}$ on $C$. It therefore computes the intersection cohomology $IH^j(C,\mathcal{V})$ and shows that it has a canonical pure Hodge structure of weight $m + j$. For more details, see Zucker’s paper [48].

### 6.3. The limit MHS on $V_P$.

Suppose that $P \in D$. For each choice of a non-zero tangent vector $\vec{v} \in T_PC$ there is a limit MHS, denoted $V_{\vec{v}}$ on $V_P$. The $p$th term of the Hodge filtration is the fiber of $F^p\nabla$ over $P$. The weight filtration is the monodromy weight filtration shifted so that its average weight is $m$, the weight of $\mathcal{V}$. The $\mathbb{Q}$ (or $\mathbb{Z}$) structure, if that makes sense, is constructed by first choosing a local holomorphic coordinate $t$ defined on a disk $\Delta$ containing $P$ where $t(P) = 0$. Assume that $\Delta \cap D = \{P\}$. Standard ODE theory (cf. [47, Chapt. II]) implies that there is a trivialization $\Delta \times V_P$ of the restriction of $\nabla$ to $\Delta$ such that the connection $\nabla$ is given by

$$\nabla f = df + N_P(f)\frac{dt}{t}$$

with respect to this trivialization, where $f : \Delta \to V_P$. Suppose that $Q \in \Delta - \{P\}$. The $\mathbb{Q}$-structure on $V_P$ corresponding to the tangent vector $\vec{v} = t(Q)\partial/\partial t$ is obtained from the $\mathbb{Q}$ structure $V_Q,\mathbb{Q}$ on $V_Q$ by identifying $V_P$ with $V_Q$ via the trivialization. This MHS depends only on the tangent vector and not on the choice of the holomorphic coordinate $t$.

For all non-zero $\vec{v} \in T_PC$, the monodromy logarithm $N_{\vec{v}} : V_{\vec{v}} \to V_{\vec{v}}$ acts as a morphism of type $(-1,-1)$. This implies that $V_{\vec{v}}/\text{im}N_P$ has a natural MHS for all $\vec{v} \neq 0$. Since $N_P$ acts trivially on this, the MHS on $V_P/\text{im}N_P$ has a natural MHS that is independent of the choice of the tangent vector $\vec{v} \in T_PC$. The definition of the weight filtration on $V_{\vec{v}}$ implies that the weight filtration on $V_P/\text{im}N_P$ is

$$W_{m+r}(V_P/\text{im}N_P) = (\text{im}N_P + \ker N_P^{-1})/\text{im}N_P$$

when $r \geq 0$ and $W_{m+r}(V_P/\text{im}N_P) = 0$ when $r < 0$.

There is a canonical isomorphism

$$H^1(\Delta - \{P\},\mathcal{V}) \cong V_P/\text{im}N_P.$$

from which it follows that this cohomology group has a canonical MHS for each $P \in D$.

### 6.4. An exact sequence.

Observe that

$$K_C(\mathcal{V})/W_mK_C(\mathcal{V}) = \bigoplus_{P \in D} i_{P*}(V_P/N_PV_P)(-1)[-1].$$
This and the exact sequence of sheaves
\[ 0 \to W_m \mathbf{K}(\mathcal{V}) \to \mathbf{K}(\mathcal{V}) \to \mathbf{K}(\mathcal{V})/W_m \to 0 \]
on C gives the exact sequence of MHS
\[ 0 \to W_{m+1} H^1(C', \mathcal{V}) \to H^1(C', \mathcal{V}) \]
\[ \to \bigoplus_{P \in D} (V_P / \text{im } N_P)(-1) \to IH^2(C, \mathcal{V}) \to 0. \]
Here we are assuming that we are in the “interesting case” where D is non-empty.
Since \( H^0(C', \mathcal{V}) = IH^0(C, \mathcal{V}) \), and since this is dual to \( IH^2(C, \mathcal{V}) \), we see that the sequence
\[ 0 \to W_{m+1} H^1(C', \mathcal{V}) \to H^1(C', \mathcal{V}) \to \bigoplus_{P \in D} (V_P / \text{im } N_P)(-1) \to 0 \]
is exact when \( H^0(C', \mathcal{V}) = 0 \).

6.5. A MHC of smooth forms. To extend this MHS from the cohomology groups \( H^1(C', \mathcal{V}) \) to one on relative completion of its fundamental group, we will need the complex part of a global MHC of smooth forms. The construction of this from \( \mathbf{K}_C(\mathcal{V}) \) is standard.
The resolution of \( \mathbf{K}_C(\mathcal{V}) \) by smooth forms is the total complex of the double complex
\[ (6.4) \quad \mathcal{K}^\bullet_\bullet(\mathcal{V}) := \mathbf{K}_C(\mathcal{V}) \otimes_{\mathcal{O}_C} \mathcal{E}^0_\bullet, \]
where \( \mathcal{E}^0_\bullet \) denotes the sheaf of smooth forms on \( C \) of type \((0, \bullet)\). The Hodge and weight filtrations extend as
\[ F^p \mathcal{K}^\bullet_\bullet(\mathcal{V}) := \mathcal{K}^{p, \bullet}_\bullet(\mathcal{V}) = (F^p \mathbf{K}_C(\mathcal{V})) \otimes_{\mathcal{O}_C} \mathcal{E}^0_\bullet \]
and
\[ W_r \mathcal{K}^\bullet_\bullet(\mathcal{V}) := (W_r \mathbf{K}_C(\mathcal{V})) \otimes_{\mathcal{O}_C} \mathcal{E}^0_\bullet. \]
The global sections
\[ K^\bullet(C, D; \mathcal{V}) := H^0(C, \text{tot } \mathcal{K}^\bullet_\bullet(\mathcal{V})); \]
of \((6.4)\) is a sub dga of \( E^\bullet(C', \mathcal{V}) \). It has Hodge and weight filtrations defined by taking the global sections of the Hodge and weight filtrations of \((6.4)\). It is the complex part of a mixed Hodge complex.
The Hodge and weight filtrations on \( H^j(C', \mathcal{V}) \) are
\[ F^p H^j(C', \mathcal{V}) = \text{im}\{ H^j(F^p K^\bullet(C, D; \mathcal{V})) \to H^j(C', \mathcal{V}) \} \]
and
\[ W_m H^j(C', \mathcal{V}) = \text{im}\{ H^j(W_{m-j} K^\bullet(C, D; \mathcal{V})) \to H^j(C', \mathcal{V}) \}. \]
Zucker’s MHC and its resolution by smooth forms are natural in the local system \( \mathcal{V} \) and are compatible with tensor products: if \( \mathcal{V}_1, \mathcal{V}_2 \) and \( \mathcal{V}_3 \) are PVHS over \( C' \), then a morphism \( \mathcal{V}_1 \otimes \mathcal{V}_2 \to \mathcal{V}_3 \) of PVHS induces morphism
\[ K(\mathcal{V}_1) \otimes K(\mathcal{V}_2) \to K(\mathcal{V}_1 \otimes \mathcal{V}_2) \to K(\mathcal{V}_3). \]
of CMHCs and dga homomorphism
\[ K^\bullet(C, D; \mathcal{V}_1) \otimes K^\bullet(C, D; \mathcal{V}_2) \to K^\bullet(C, D; \mathcal{V}_1 \otimes \mathcal{V}_2) \to K^\bullet(C, D; \mathcal{V}_3) \]
that preserve the Hodge and weight filtrations.
6.6. **Remarks about the orbifold case.** Zucker’s work extends formally to the orbifold case. For us, an orbicurve $C' = C - D$ is the orbifold quotient of a smooth curve $X' = X - E$ by a finite group $G$. This action does not have to be effective. (That is, $G \to \text{Aut} X$ does not have to be injective.) An orbifold variation of MHS $\mathbb{V}$ over $C'$ is an admissible variation of MHS $\mathbb{V}_X$ over $X'$ together with a $G$-action such that the projection $\mathbb{V} \to X'$ is $G$-equivariant. For each $g \in G$, we require that the map $g : \mathbb{V}_X \to \mathbb{V}_X$ induce an isomorphism of variations of MHS $g^* \mathbb{V}_X \cong \mathbb{V}$.

With these assumptions, $G$ acts on $K^*(X, E; \mathbb{V}_X)$ and $K^*(X, E; \mathbb{V}_X)^G$ is a sub MHC. Define

$$K^*(C, D; \mathbb{V}) = K^*(X, E; \mathbb{V}_X)^G.$$ 

This computes the cohomology $H^*(C', \mathbb{V})$ and implies that it has a MHS such that the canonical isomorphism $H^*(C', \mathbb{V}) \cong H^*(X', \mathbb{V}_X)^G$ is an isomorphism of MHS.

7. **Relative Completion of Fundamental Groups of Affine Curves**

In this section we use the results of the last two sections to construct, under suitable hypotheses, a MHS on relative completion of the fundamental group of an affine curve. As in the previous section, we suppose that $C'$ is a compact Riemann surface and that $D$ is a finite subset of $C$. Here we suppose, in addition, that $D$ is non-empty, so that $C' = C - D$ is an affine curve. Suppose that $\mathbb{V}$ is a polarized variation of $\mathbb{Q}$-HS over $C'$ with unipotent monodromy about each $P \in D$. Denote the fiber of $\mathbb{V}$ over $x$ by $V_x$. The Zariski closure of the monodromy representation

$$\rho : \pi_1(C, x) \to \text{Aut}(V_x)$$

is a reductive $\mathbb{Q}$-group [42, Lem. 2.10], which we will denote by $R_x$. Fix a base point $x_0 \in C$. Set $R = R_{x_0}$. Each monodromy group $R_x$ is isomorphic to $R$; the isomorphism is unique mod inner automorphisms. We thus have Zariski dense monodromy representations

$$\rho_x : \pi_1(C, x) \to R_x(\mathbb{Q})$$

for each $x \in X$. Denote the completion of $\pi_1(C', x)$ with respect to $\rho_x$ by $\mathcal{G}_x$, and its Lie algebra by $\mathfrak{g}_x$. We will construct a natural MHSs on $\mathcal{O}(\mathcal{G}_x)$ and on $\mathfrak{g}_x$ that are compatible with their algebraic structures (Hopf algebra, Lie algebra). Before doing this we need to show that the connection form $\Omega$ can be chosen to have coefficients in Zucker’s MHC and be compatible with the various Hodge and weight filtrations.

For simplicity, we make the following assumptions:

(i) Every irreducible representation of $R$ is absolutely irreducible. That is, it remains irreducible when we extend scalars from $\mathbb{Q}$ to $\mathbb{C}$.

(ii) For each irreducible representation $\mathcal{V}_\lambda$ of $R$, the corresponding local system $\mathcal{V}_\lambda$ over $C'$ underlies a PVHS over $C'$. The Theorem of the Fixed Part (stated below) implies that this PVHS is unique up to Tate twist.

These hold in our primary example, where $C'$ is a modular curve and $R \cong SL_2$.

7.1. **The bundle $\mathfrak{u}$ of Lie algebras.** Denote the set of isomorphism classes of irreducible $R$-modules by $\hat{R}$. Fix a representative $\hat{V}_\lambda$ of each $\lambda \in \hat{R}$ and the structure of a PVHS on the corresponding local system $\mathcal{V}_\lambda$ over $C'$. Filter

$$\hat{R}_1 \subset \hat{R}_2 \subset \hat{R}_3 \subset \cdots \subset \bigcup_{n=1}^{\infty} \hat{R}_n = \hat{R}.$$
by finite subsets such that if \( \lambda \in \check{R} \) and \( \mu \in \check{R} \), then the isomorphism class of \( V_\lambda \otimes V_\mu \) is in \( \check{R} \). For example, when \( R = \text{SL}_2 \), \( \check{R} \) will consist of all symmetric powers \( S^m H \) with \( m \leq n \) of the defining representation \( H \) of \( \text{SL}_2 \).

For each \( \lambda \in \check{R} \), the variation MHS \( H^1(C', V_\lambda)^* \otimes V_\lambda \), being the tensor product of a constant MHS with a PVHS, is an admissible variation of MHS over \( C' \). Note that the VMHS structure on it does not change when \( V_\lambda \) is replaced by \( \check{V}_\lambda(n) \), so that the VMHS \( H^1(C', \check{V}_\lambda)^* \otimes \check{V}_\lambda \) is independent of the choice of the PVHS structure on \( \check{V}_\lambda \). Since the weights of \( H^1(C, \check{V}_\lambda) \) are at least \( 1+ \) the weight of \( \check{V}_\lambda \), the weights of \( H^1(C', \check{V}_\lambda)^* \otimes \check{V}_\lambda \) are \( \leq -1 \).

The inverse limit
\[
\mathfrak{u}_1 := \lim_{\longleftarrow n} \bigoplus_{\lambda \in \check{R}} H^1(C', V_\lambda)^* \otimes \check{V}_\lambda
\]
is pro-variation of MHS over \( \mathbb{C} \) of negative weight.\(^8\) That is, \( \mathfrak{u}_1 = W_{-1} \mathfrak{u}_1 \). Observe that its fiber
\[
\lim_{\longleftarrow n} \bigoplus_{\lambda \in \check{R}} H^1(C', V_\lambda)^* \otimes V_\lambda, o = \prod_{\lambda \in \check{R}} H^1(C', V_\lambda)^* \otimes V_\lambda, o
\]
over \( x_o \) is the the abelianization of the prounipotent radical of the completion of \( \pi_1(C', x_o) \) with respect to the homomorphism to \( \check{R} \).

The degree \( n \) part \( V \to L_n(V) \) of the free Lie algebra is a Schur functor, so that it makes sense to apply it to bundles. Set
\[
\mathfrak{u}_n = L_n(\mathfrak{u}_1) := \lim_{\longleftarrow n} L_n \left( \bigoplus_{\lambda \in \check{R}} H^1(C', V_\lambda)^* \otimes \check{V}_\lambda \right)
\]
and
\[
\mathfrak{u} := \lim_{\longleftarrow n} \bigoplus_{j=1}^n \mathfrak{u}_j \quad \text{and} \quad \mathfrak{u}^N := \lim_{n \geq N} \bigoplus_{j=N}^n \mathfrak{u}_j.
\]
These are admissible pro-variations of MHS over \( C' \). The denote the fiber of \( \mathfrak{u} \) over \( x \) by \( \mathfrak{u}_x \). It is abstractly isomorphic to the prounipotent radical of the completion of \( \pi_1(C', x) \) relative to the monodromy representation \( \pi_1(C', x) \to R(\mathbb{Q}) \). The fiber of \( \mathfrak{u}^N \) over \( x \) is the \( n \)th term \( L^n \mathfrak{u}_x \) of the lower central series (LCS) of \( \mathfrak{u}_x \).

7.2. Some technicalities. The Theorem of the Fixed Part states that if \( \mathbb{A} \) is an admissible VMHS over a smooth variety \( X \), then \( H^0(X, \mathbb{A}) \) has a natural MHS with the property that for each \( x \in X \), the natural inclusion \( H^0(X, \mathbb{A}) \to A_x \) is a morphism of MHS. In the algebraic case, it is enough to prove this when \( X \) is a curve. When \( \mathbb{A} \) is pure, this follows from Zucker’s MHS [48] on \( H^*(X, V) \). The general case follows from Saito’s theory of Hodge and mixed Hodge modules [37, 38].

The following is a direct consequence of the Theorem of the Fixed Part. Its proof is left as an exercise.

**Lemma 7.1.** Assume that \( \mathbb{A} \) is an admissible VMHS over \( C' \) whose monodromy representation \( \pi_1(C', x_o) \to \text{Aut} A_{x_o} \) factors through \( \pi_1(C', x_o) \to R \). With the assumptions above, each \( R \) isotypical component of \( \mathbb{A} \) over \( C' \) is an admissible

\(^8\)Note that this is a very special kind of variation of MHS — it is a direct sum of variations that are the tensor product of a constant MHS with a PVHS. Their asymptotic behaviour is determined by that of the PVHS that occur in the summands.
VMHS. If $\mathcal{V}_\lambda$ is a PVHS that corresponds to the irreducible $R$-module $V_\lambda$, then the natural mapping

$$\bigoplus_{\lambda \in \mathcal{R}} H^0(C', \mathcal{V}_\lambda) \otimes V_\lambda \to \mathcal{A}$$

is an isomorphism of admissible VMHS. In particular, the structure of a PVHS on $\mathcal{V}_\lambda$ is unique up to Tate twist.

Every pro object of the category of admissible VMHS $\mathcal{A}$ over $C'$ is thus of the form

$$\mathcal{A} = \prod_{\lambda \in \mathcal{R}} \mathcal{V}_\lambda \otimes A_\lambda,$$

where each $A_\lambda$ is a MHS. Define

$$K(\mathcal{A}) = \prod_{\lambda \in \mathcal{R}} K(\mathcal{V}_\lambda) \otimes A_\lambda.$$ 

This is a pro-CMHC. In particular, its complex part

$$K^\bullet(C, D; \mathcal{A}) = \prod_{\lambda \in \mathcal{R}} K^\bullet(C, D; \mathcal{V}_\lambda) \otimes A_\lambda.$$ 

has naturally defined Hodge and weight filtrations; its differential is strict with respect to the Hodge and weight filtrations (cf. Lemma 6.1). In particular, for all $n \geq 1$, the complexes $K^\bullet(C, D, u_n)$ have this strictness property.

7.3. The connection form $\Omega$. Observe that $H^1(C', H^1(C', \mathcal{V}_\lambda)^* \otimes \mathcal{V}_\lambda)$ is naturally isomorphic (as a MHS) to

$$H^1(C', \mathcal{V}_\lambda) \otimes H^1(C', \mathcal{V}_\lambda)^* \cong \text{Hom}(H^1(C', \mathcal{V}_\lambda), H^1(C', \mathcal{V}_\lambda)).$$

So, for each $\lambda \in \mathcal{R}$, there is an element $\xi_\lambda \in F^0W_0H^1(C', H^1(C', \mathcal{V}_\lambda)^* \otimes \mathcal{V})$ that corresponds to the identity mapping $H^1(C', H^1(C', \mathcal{V}_\lambda)) \to H^1(C', H^1(C', \mathcal{V}_\lambda))$. Lemma 6.1 implies that this is represented by a 1-form

$$\omega_\lambda \in F^0W_{-1}K^1(C, D; H^1(C', \mathcal{V}_\lambda)^* \otimes \mathcal{V}_\lambda).$$

Set

$$\Omega_1 := \prod_{\lambda \in \mathcal{R}} \omega_\lambda \in K^1(C, D; u_1).$$

Note that $d\Omega_1 = 0$ and that

$$\frac{1}{2}[\Omega_1, \Omega_2] \in F^0W_{-2}K^2(C, D; u_2).$$

Since $C$ is a surface, $[\Omega_1, \Omega_2]$ is closed. Since $C'$ is not compact, it is exact. Lemma 6.1 implies that we can find $\Xi_2$ in $F^0W_{-1}K^1(C, D; u_2)$ such that $d\Xi_2 = \frac{1}{2}[\Omega_1, \Omega_2]$. Set

$$\Omega_2 = \Omega_1 - \Xi_2 \in F^0W_{-1}K^1(C, D; u_1 \oplus u_2).$$

Then

$$d\Omega_2 + \frac{1}{2}[\Omega_2, \Omega_2] \in F^0W_{-2}K^2(C, D; u^3).$$

Its degree 3 part is closed and thus exact. So it is the exterior derivative of some $\Xi_3 \in F^0W_{-1}K^1(C, D; u_1 \oplus u_2 \oplus u_3)$. Set

$$\Omega_3 = \Omega_2 - \Xi_3 \in F^0W_{-1}K^1(C, D; u_1 \oplus u_2 \oplus u_3).$$
Then
\[ d\Omega_3 + \frac{1}{2}[\Omega_3, \Omega_3] \in F^0W_{-2}K^2(C, D; \mathfrak{u}^4). \]
Continuing this way, we obtain a sequence of elements \( \Xi_n \in F^0W_{-1}K^1(C, D; \mathfrak{u}_n) \) such that for all \( N \geq 2 \)
\[ \Omega_N := \Omega_1 - (\Xi_2 + \cdots + \Xi_N) \in F^0W_{-1}K^1(C, D; \oplus_{n=1}^N \mathfrak{u}_n) \]
satisfies
\[ d\Omega_N + \frac{1}{2}[[\Omega_N, \Omega_N]] \in F^0W_{-2}K^2(C, D; \mathfrak{u}^{N+1}). \]
Then the \( \mathfrak{u} \)-valued 1-form
\[ \Omega := \lim_{\rightarrow N} \Omega_N \in F^0W_{-1}K^1(C, D; \mathfrak{u}) \]
is integrable:
\[ d\Omega + \frac{1}{2}[[\Omega, \Omega]] = 0. \]
To understand the significance of the form \( \Omega \), note that the bundle \( \mathfrak{u}_1 \) over \( C' \), and hence each \( \mathfrak{u}_n = \mathbb{L}_n(\mathfrak{u}_1) \), is a flat bundle over \( C' \). The monodromy of each factors through the representation \( \rho_x : \pi_1(C', x) \to R \). Summing these, we see that for each \( N \geq 1 \), the bundle
\[ \mathfrak{u}/\mathfrak{u}^{N+1} \cong \mathfrak{u}_1 \oplus \cdots \oplus \mathfrak{u}_N \]
is flat with monodromy that factors through \( \rho_x \). Denote the limit of these flat connections by \( \nabla_0 \). Then
\[ \nabla := \nabla_0 + \Omega \]
defines a new connection on the bundle \( \mathfrak{u} \) over \( C' \) which is flat as \( \Omega \) is integrable. Here we view \( \mathfrak{u} \) (and hence \( \Omega \)) as acting on each fiber by inner derivations.

The restriction of the filtration
\[ \mathfrak{u} = \mathfrak{u}^1 \supset \mathfrak{u}^2 \supset \mathfrak{u}^3 \supset \cdots \]
of \( \mathfrak{u} \) to each fiber is the lower central series. Note that
\[ \text{Gr}^\bullet_{\text{LCS}} \mathfrak{u} := \mathfrak{u}^n/\mathfrak{u}^{n+1} \]
is naturally isomorphic to \( \mathfrak{u}_n \).

**Lemma 7.3.** Each term \( \mathfrak{u}^n \) of the lower central series filtration of \( \mathfrak{u} \) is a flat subbundle of \( (\mathfrak{u}, \nabla) \). The induced connection on \( \text{Gr}^\bullet_{\text{LCS}} \mathfrak{u} \cong \mathfrak{u}_n \) is \( \nabla_0 \).

**Proof.** This follows from the fact that \( \Omega \) takes values in \( \mathfrak{u} \) and that the inner derivations act trivially on \( \text{Gr}^\bullet_{\text{LCS}} \mathfrak{u} \). \( \square \)

7.4. **Hodge and weight bundles and their extensions to \( C \).** The flat connection \( \nabla \) on \( \mathfrak{u} \) defines a new complex structure as a (pro) holomorphic vector bundle over \( C' \). To understand it, write \( \Omega = \Omega' + \Omega'' \), where \( \Omega' \) is of type \((1, 0)\) and \( \Omega'' \) is of type \((0, 1)\). Set
\[ D' = \nabla_0 + \Omega' \text{ and } D'' = \bar{\partial} + \Omega'' \]
so that \( \nabla = D' + D'' \). Then \( D'' \) is a \((0, 1)\)-valued form taking values in \( \mathfrak{u} \). Note that \((D'')^2 = 0 \).

**Lemma 7.4.** A section \( s \) of \( \mathfrak{u} \) is holomorphic with respect the complex structure on \( \mathfrak{u} \) defined by the flat connection \( \nabla \) if and only if \( D'' s = 0 \).
Proof. Since $D''$ is $O_C$-linear, it suffices to show that $D''s = 0$ when $s$ is a flat local section of $\mathfrak{u}$. But this follows as $D''s$ is the $(0, 1)$ component of $\nabla s$, which vanishes as $s$ is flat.  

Denote $\mathfrak{u}$ with this complex structure by $(\mathfrak{u}, D'')$. Since all holomorphic sections of $(\mathfrak{u}, D'')$ are $O$-linear combinations of flat sections, Lemma 7.3 implies:  

\textbf{Lemma 7.5.} The lower central series filtration (7.2) of $\mathfrak{u}$ is a filtration by holomorphic sub-bundles. The isomorphism  

$\text{Gr}_{LCS}^{n}(\mathfrak{u}, D'') \cong \mathfrak{u}_n$  

is an isomorphism of holomorphic vector bundles.  

Denote the canonical extension of $\mathfrak{u}_1$ to $C$ by $\mathfrak{u}_1$. Then, since the local monodromy operators are unipotent, $\mathfrak{u}_n := \mathbb{L}_n(\mathfrak{u}_1)$ is the canonical extension of $\mathfrak{u}_n$ to $C$. Define  

$$
\mathfrak{u} := \lim_{\longrightarrow} \bigoplus_{j=1}^n \mathfrak{u}_j \quad \text{and} \quad \mathfrak{u}^N := \lim_{\longrightarrow} \bigoplus_{n \geq N, j=1}^n \mathfrak{u}_j.
$$

Then $(\mathfrak{u}, \nabla_0)$ is the canonical extension of $(\mathfrak{u}, \nabla)$ to $C$.  

Our next task is to show that $(\mathfrak{u}, \nabla)$ is the canonical extension of $(\mathfrak{u}, \nabla)$ to $C$. Since smooth logarithmic $(0, 1)$-forms on $C$ with poles on $\mathcal{D}$ are smooth on $C$, it follows that $\Omega''$ is a smooth, $\mathfrak{u}$-valued $(0, 1)$-form on $C$. It follows that $D''$ extends to a $(0, 1)$ form-valued operator on smooth sections of $\mathfrak{u}$. Since $(D'')^2 = 0$, it defines a complex structure on $\mathfrak{u}$. A smooth locally defined section $s$ of $\mathfrak{u}$ is holomorphic if and only if $D''s = 0$. We'll denote this complex structure by $(\mathfrak{u}, D'')$.  

Suppose that $P \in \mathcal{D}$ and that $t$ is a local holomorphic coordinate on $C$ centered at $P$. Since $t\Omega$ is a smooth $\mathfrak{u}$-valued form on $C$ in a neighbourhood $\Delta$ of $P$, and since $t\nabla_0$ takes smooth sections of $\mathfrak{u}$ defined on $\Delta$ to smooth $1$-forms with values in $\mathfrak{u}$, it follows that $t\nabla$ is a differential operator on sections of $\mathfrak{u}$ over $\Delta$. This implies that $\nabla$ is a meromorphic connection on $(\mathfrak{u}, D'')$ with regular singular points along $\mathcal{D}$.  

\textbf{Proposition 7.6.} The bundle $(\mathfrak{u}, D'')$ with the connection is Deligne’s canonical extension of $(\mathfrak{u}, \nabla)$ to $C$.  

\textit{Proof.} Since all singularities of $\nabla$ are regular singular points, it suffices to check that the residue of $\nabla$ at each $P \in \mathcal{D}$ is pronilpotent endomorphism of $\mathfrak{u}_P$, the fiber of $\mathfrak{u}$ over $P$. This is an immediate consequence of the fact that the residue of $(\text{Gr}_{LCS}^\bullet \mathfrak{u}, \nabla) \cong (\mathfrak{u}, \nabla_0)$ at $P$ is pronilpotent by assumption and that the residue of $\Omega$ at $P$ is an element of $\mathfrak{u}_P$, which acts trivially on $\text{Gr}_{LCS}^\bullet \mathfrak{u}_P$.  

We now turn out attention to the behaviour of the Hodge bundles. Since each $\mathfrak{u}_n$ is a sum of variations of MHS that are tensor products of a constant MHS with a PVHS, they behave well near each cusp $P \in \mathcal{D}$. In particular, the Hodge bundles $F^p\mathfrak{u}_n$ extend to sub-bundles of $\mathfrak{u}_n$. This implies that the the Hodge bundles $F^p\mathfrak{u}$ extend to holomorphic sub-bundles of $\mathfrak{u}$. Consequently, they extend as $C^\infty$ sub-bundles of $(\mathfrak{u}, D'')$.  

---

9This also follows from the fact that $\Omega''$ is $\mathfrak{u}$-valued thus acts trivially on the graded quotients of the lower central series filtration of $\mathfrak{u}$.
Lemma 7.7. The Hodge sub-bundles of $\overline{u}$ are holomorphic and the connection $\nabla$ satisfies Griffiths transversality: if $s$ is a local holomorphic section of $F^p\overline{u}$, then $\nabla s$ is a local section $\Omega^1_c(\log D) \otimes F^p\overline{u}$.

Proof. To prove that $F^p\overline{u}$ is a holomorphic sub-bundle with respect to the complex structure $D''$, it suffices to show that if $s$ is a local $C^\infty$ section of $F^p\overline{u}$, then $D''s$ is a $(0,1)$-form with values in $F^p\overline{u}$. Since $F^p\overline{u}$ is a holomorphic sub-bundle of $(u, \partial\overline{s})$, it follows that $\partial s$ is a $(0,1)$-form with values in $F^p\overline{u}$. And since

$$\Omega'' \in F^0 K^{0,1}(C, D; u) = E^{0,1}(C) \otimes F^p\overline{u},$$

it follows that $\Omega''(s) \in E^{0,1}(C) \otimes F^p\overline{u}$, which implies that $D''s \in E^{0,1}(C) \otimes F^p\overline{u}$, as required.

Griffiths transversality follows for similar reasons. Suppose that $s$ is a local $C^\infty$ section of $F^p\overline{u}$. Since $(u, \nabla_0)$ satisfies Griffiths transversality, $\nabla_0 s$ is a 1-form valued section of $F^{p-1}\overline{u}$. Since

$$\Omega \in F^0 K^{1}(C, D; u) \subseteq E^1(C \log D) \otimes F^{-1}\overline{u},$$

$\Omega(s)$ is a 1-form valued section of $F^{p-1}\overline{u}$. It follows that $\nabla(s)$ takes values in $F^{-1}\overline{u}$. \hfill \Box

Lemma 7.8. The weight sub-bundles $W_n u$ are flat sub-bundles of $(\overline{u}, \nabla)$. Moreover, the identity induces an isomorphism of PVHS

$$(\text{Gr}_m W \overline{u}, \nabla) \cong (\text{Gr}_m \overline{u}, \nabla_0).$$

Proof. Both assertions follow from the fact that $\Omega$ (and hence $\Omega''$ as well) takes values in $u$ and that $u = W_n u$. This implies that the adjoint action of $\Omega$ and $\Omega''$ on $\text{Gr}_m u$ is trivial. It follows that $\nabla$ respects the weight filtration of $u$ and that the induced connection on $\text{Gr}_m W u$ is $\nabla_0$. \hfill \Box

Since $\Omega$ acts trivially on $\text{Gr}_m^{\text{LCS}} u$, we have:

Lemma 7.9. For all $n \geq 1$ there is a natural isomorphism of

$$(\text{Gr}_m^{\text{LCS}} u, \nabla) \cong (\text{Gr}_m^{\text{LCS}} u, \nabla_0) \cong u_n$$

local systems. \hfill \Box
representation $V_\lambda$ of $R$ is absolutely irreducible and that the corresponding local system $V_\lambda$ underlies a PVHS over $C'$, there is an isomorphism of HS

$$\mathcal{O}(R_{x,y}) \cong \bigoplus_\lambda \text{Hom}(V_{\lambda,x}, V_{\lambda,y})^*. $$

When $C'$ is a modular curve and $\mathbb{H}$ is the standard variation of HS,

$$\mathcal{O}(R_{x,y}) = \bigoplus_{n \geq 0} \text{Hom}(S^n H_x, S^n H_y)^*. $$

Denote the local system over $C'$ whose fiber over $y$ is $\mathcal{O}(R_{y,x})$ by $\mathcal{O}_x$. In concrete terms

$$\mathcal{O}_x = \bigoplus_\lambda \text{Hom}(V_\lambda, V_{\lambda,x})^* \cong \bigoplus_\lambda V_{\lambda} \otimes V_{\lambda,x}^*. $$

Note that this local system of algebras and that there is a natural left $R_x$ action that preserves the algebra structure.

For every local system $E$ whose monodromy representation factors through $\rho : \pi_1(X, x) \to R_x$, there is a natural isomorphism

$$(7.11) \quad V \cong [\mathcal{O}_x \otimes E_x]^R$$

The $R$-finite vectors in the de Rham complex of $C'$ with coefficients in $\mathcal{O}_x$ forms a complex $E_{\text{fin}}^*(C', \mathcal{O}_x)$. In concrete terms, this is

$$E_{\text{fin}}^*(C', \mathcal{O}_x) = \bigoplus_\lambda E^*(C', V_\lambda) \otimes V_{\lambda,x}^*. $$

It is a (graded commutative) differential graded algebra. Similarly, one defines the ind-MHC

$$K(\mathcal{O}_x) = \bigoplus_\lambda K(V_\lambda) \otimes V_{\lambda,x}^*$$

whose complex part is

$$K^*(C, D; \mathcal{O}_x) = \bigoplus_\lambda K^*(C, D; V_\lambda) \otimes V_{\lambda,x}^*.$$

The relevance of these complexes is that the iterated integrals of their elements are elements of the coordinate ring of $G_x$. (Cf. [16].)

**Lemma 7.12.** If $E$ is a PVHS over $C'$, then there the isomorphism (7.11) induces an isomorphism of bifiltered complexes:

$$K^*(C, D; E) \cong (K^*(C, D; \mathcal{O}_x) \otimes E)^R. \quad \square$$

The relevance of the preceding discussion is that iterated integrals of elements of $E_{\text{fin}}^*(C', \mathcal{O}_x)$ considered in [16]. This implies that the iterated Shimura integrals considered by Manin [32, 33] are examples of the iterated integrals constructed in [16].
7.6. The MHS on the relative completion of $\pi_1(C', x)$. Denote the fiber of $\mathbf{u}$ over $x \in C'$ by $u_x$. Denote the corresponding prounipotent group by $U_x$. The Hodge and weight bundles of $\mathbf{u}$ restrict to Hodge and weight filtrations on $u_x$. Set $\Gamma = \pi_1(C', x)$ and write $C'$ as the quotient $\Gamma \backslash X$ of a simply connected Riemann surface by $\Gamma$. Implicit here is that we have chosen a point $\tilde{x} \in X$ that lies over $x \in C'$.

Trivialize the pullback of each local system $\mathbf{u}_n$ to $X$ so that the flat sections are constant. This determines a trivialization of the pullback of $\mathbf{u}_n$ to $X$ as the product of the pullbacks of the $\mathbf{u}_n$. The pullback of the connection $\nabla = \nabla_0 + \Omega$ on $\mathbf{u}$ is $\Gamma$-invariant with respect to the diagonal $\Gamma$-action on $X \times u_x$ and is of the form $d + \tilde{\Omega}$, where 

$$\tilde{\Omega} \in (E^1(X) \otimes u_x)^\Gamma.$$ 

Proposition 4.6 and the fact that $\Omega_1$ represents the product of the identity maps $H^1(C', V_\lambda) \rightarrow H^1(C', V_\lambda)$ for all $\lambda \in \check{R}$ imply that the transport of $\tilde{\Omega}$ induces an isomorphism $\Theta_x : G_x \rightarrow R_x \ltimes U_x$.

The MHS on $\mathcal{O}(G_x)$ is constructed by pulling back the natural Hodge and weight filtrations on $\mathcal{O}(R_x) \otimes \mathcal{O}(U_x)$, which we now recall.

To describe $\mathcal{O}(U_x)$ we recall some basic facts about prounipotent groups. Suppose that $\mathcal{N}$ is a prounipotent group over $\mathbb{F}$ with Lie algebra $\mathfrak{n}$. The enveloping algebra $U\mathfrak{n}$ of $\mathfrak{n}$ is a Hopf algebra. The exponential mapping $\exp : \mathfrak{n} \rightarrow \mathcal{N}$ is a bijection, so we can identify $\mathcal{N}$ with the subspace $\mathfrak{n}$ of $U\mathfrak{n}$. The Poincaré-Birkhoff-Witt Theorem implies that the restriction mapping induces a Hopf algebra isomorphism 

$$\text{Hom}^{\text{cts}}(U\mathfrak{n}, \mathbb{F}) \cong \text{Sym}^{\text{cts}}(\mathfrak{n}) \cong \mathcal{O}(\mathcal{N}).$$

In particular, $\mathcal{O}(U_x) \cong \text{Hom}^{\text{cts}}(Uu_x, \mathbb{C})$. The construction of the Hodge and weight filtrations of $u_x$ and (7.10) imply that the coaction (7.13) 

$$Uu_x \rightarrow \mathcal{O}(R_x) \otimes Uu_x$$

that defines the semi direct product $R_x \ltimes U_x$ preserves the Hodge and weight filtrations.\(^{11}\)

\(^{10}\)It is also natural to trivialize $\mathbf{u}_1$ (and hence all $\mathbf{u}_n$) so that the Hodge bundles are trivialized. In this case, we are in the setup of Section 4.1. The monodromy representation will be the same as it is with this “constant trivialization”. Trivializing the Hodge bundles is better when computing the MHS on completed path torsors. For example, in Section 9.1, we can trivialize $\mathcal{H} := \mathbb{H} \otimes \mathfrak{h}$ over the upper half plane $\mathbb{H}$ using the flat sections $\mathbf{a}, \mathbf{b}$, as we do here, or we can use the sections $\mathbf{a}, \mathbf{w}$ that are adapted to the Hodge filtration. The second trivialization is better suited to studying asymptotic properties of VMHS.

\(^{11}\)In fact, this is a morphism of MHS — and thus strict with respect to Hodge and weight filtrations — if we give $u_x$ MHS via the identification $u_x \cong \prod_{\lambda} (\text{Gr}_n^{\text{HSS}} u_x)$. The canonical MHS on $u_x$ has the same underlying complex vector space, the same Hodge and weight filtrations, but its $\mathbb{Q}$-structure is deformed using the deformed connection $\Omega$. 

---

\(\mathcal{O}\)
The Hodge and weight filtrations of $u_x$ induce Hodge and weight filtrations on $\text{Hom}^{\text{cts}}(Uu_x, \mathbb{C})$, and thus on $O(U_x)$. Define Hodge and weight filtrations on the coordinate ring of $R_x \ltimes U_x$ via the canonical isomorphism

$$O(R_x \ltimes U_x) \cong O(R_x) \otimes O(U_x).$$

These pullback to Hodge and weight filtrations on $O(G_x)$ along the isomorphism $\Theta_x$. Equation (7.13) implies that these are compatible with the product and coproduct of $O(R_x \ltimes U_x)$.

A filtration $W_\bullet$ of a Lie algebra $u$ is said to be compatible with the bracket if $[W_i u, W_j u] \subseteq W_{i+j} u$ for all $i, j$. Similarly, a filtration $W_\bullet$ of a Hopf algebra $A$ is compatible with its multiplication $\mu$ and comultiplication $\Delta$ if $\mu(W_i A \otimes W_j A) \subseteq W_{i+j} A$ and $\Delta(W_m A) \subseteq \sum_{i+j} W_i A \otimes W_j A$. The Hodge and weight filtrations on $O(R_x \ltimes U_x)$ defined above are compatible with its product and coproduct.

Denote the maximal ideal of $O(G_x)$ of functions that vanish at the identity by $m_x$. The Lie algebra $g_x$ of $G_x$ is isomorphic to $\text{Hom}(m_x/m_x^2, F)$ and its bracket is induced by the Lie cobracket of $O(G_x)$. The Hodge and weight filtrations of $O(G_x)$ thus induce Hodge and weight filtrations on $g_x$ that are compatible with its bracket.

**Theorem 7.14.** These Hodge and weight filtrations define a MHS on $O(G_x)$ for which the multiplication and comultiplication are morphisms. This MHS agrees with the one constructed in [16].

**Proof.** The natural isomorphism $\Theta^*_x : O(R_x \ltimes U_x) \to O(G_x)$ respects $\mathbb{Q}$-structures (essentially by definition). To prove the result it suffices to show that it takes the Hodge and weight filtrations on $O(R_x \ltimes U_x)$ constructed above onto the Hodge and weight filtrations of the canonical MHS on $O(G_x)$ constructed in [16]. This will imply that the weight filtration defined on $O(R_x \ltimes U_x)$ above is defined over $\mathbb{Q}$ and that $O(R_x \ltimes U_x)$ has a MHS and that this MHS is isomorphic to the canonical MHS on $O(G_x)$ via $\Theta_x^*$.

The first point is that Saito’s MHC for computing the MHS on $H^\bullet(C', V)$, which is used in [16], is a generalization of Zucker’s MHC used here and agrees with it in the curve case. The iterated integrals of elements of $K^\bullet(C, D; V) \otimes V^*_x$ in this paper are a special case of the iterated integrals defined in [16, §5] by Lemma 7.12.

The next point is that, by Lemma 7.12

$$\Omega \in T^{0}W_{-1}K^{1}(C, D; u) \cong F^{0}W_{-1}(K^{1}(C, D; O_x) \otimes u_x).$$

This implies, and this is the key point, that — with the Hodge and weight filtrations on the bar construction defined in [16, §13] and the Hodge and weight filtrations on $u_x$ defined above — the $Uu_x$-valued formal transport

$$T := 1 + [\hat{\Omega}] + [\hat{\Omega}[\hat{\Omega}]] + [\hat{\Omega}[\hat{\Omega}[\hat{\Omega}]]] + \cdots \in B(C, K_{\text{hm}}^\bullet(C, D; O_x), \mathbb{C}) \otimes Uu_x$$

of $\hat{\Omega}$, which takes values in the completed enveloping algebra of $u_x$, satisfies

$$T \in F^{0}W_{0}H^{0}\left(B(C, K_{\text{hm}}^\bullet(C, D; O_x), \mathbb{C}) \otimes Uu_x\right).$$

This implies that the induced Hopf algebra homomorphism

$$f : O(U_x) \cong \text{Hom}^{\text{cts}}(Uu_x, \mathbb{C}) \to H^{0}\left(B(C, K_{\text{hm}}^\bullet(C, D; O_x), O(R_x))\right) \cong O(G_x)$$

decorresponds to the function

$$G_x \xrightarrow{\Theta_x} R_x \ltimes U_x \xrightarrow{\text{proj}} U_x.$$
preserves the Hodge and weight filtrations.

The constructions in [16] imply that the homomorphism $\pi^* : \mathcal{O}(R_x) \to \mathcal{O}(G_x)$ induced by the projection $\pi : G_x \to R_x$ is a morphism of MHS. Since the Hodge and weight filtrations of $\mathcal{O}(G_x)$ are compatible with multiplication and since both $f$ and $\pi^*$ preserve the Hodge and weight filtrations, the homomorphism

$$\mathcal{O}(R_x) \otimes \mathcal{O}(U_x) \xrightarrow{\pi^* \otimes f} \mathcal{O}(G_x)$$

do does too. This homomorphism is $\Theta^*$ when $\mathcal{O}(R_x) \otimes \mathcal{O}(U_x)$ is identified with $\mathcal{O}(R_x \ltimes U_x)$.

It remains to prove that this isomorphism is an isomorphism of bifiltered vector spaces. Since $\pi^*$ is a morphism of MHS, it suffices to show that the isomorphism $j^* \circ f$

$$\mathcal{O}(U_x) \xrightarrow{f} \mathcal{O}(G_x) \xrightarrow{j^*} \mathcal{O}(N_x),$$

where $j : N_x \to G_x$ is the inclusion of the pronipotent radical of $G_x$, is a bifiltered isomorphism. To prove this, it suffices to show that $n_x \to u_x$ is a bifiltered isomorphism, where $n_x$ denotes the Lie algebra of $N_x$. But this follows from Lemma 7.9, which implies that $H_1(u_x)$ has a MHS and that the induced homomorphism

$$\text{Gr}_{LCS}^\bullet n_x \to \text{Gr}_{LCS}^\bullet u_x$$

is an isomorphism of graded MHS. □

The result also gives an explicit description of the MHS on $u_x$.

**Corollary 7.15.** The Hodge and weight filtrations of the natural MHS on $u_x$ are those induced on it from $u$; its $\mathbb{Q}$-structure is the one described in Proposition 4.7. □

To complete the story, we show that the $u$ is a pro-admissible variation of MHS.

**Theorem 7.16.** With the Hodge and weight filtrations and $\mathbb{Q}$-structure defined above, $(u, \nabla)$ is a pro-object of the category of admissible variation of MHS over $C'$. Its lower central series is a filtration of $u$ by pro-admissible variations of MHS. The natural isomorphism

$$(\text{Gr}_{LCS}^n u, \nabla_0) \cong (\text{Gr}_{LCS}^n u, \nabla)$$

is an isomorphism of admissible variations of MHS. In particular, there are natural MHS isomorphisms

$$H_1(u_x) \cong \prod_{\lambda \in R} H^1(C', \mathcal{V}_\lambda)^* \otimes V_{\lambda, x}$$

for all base points $x$ of $C'$.\(^{12}\) Finally, for all PVHS $\mathcal{V}$ over $C'$ whose monodromy representation factors through $\rho$, the natural homomorphism

$$H^\bullet(g_x, V_x)^{\text{tor}(R)} = [H^\bullet(u_x) \otimes V_x]^R \to H^\bullet(C', \mathcal{V})$$

is an isomorphism of MHS.

With a little more work, one can show that the local system with fiber $\mathcal{O}(G_x)$ over $x \in C'$ is an admissible VMHS.

\(^{12}\)This statement holds, even when $x$ is a tangential base point.
Proof. Proposition 7.6 and Lemma 7.7 imply that the Hodge bundles are holomorphic sub-bundles of $\mathfrak{u}$ and extend to holomorphic sub-bundles of $\overline{\mathfrak{u}}$. Lemma 7.8 implies that $\mathfrak{u}$ has a natural $\mathbb{Q}$-form and that, with respect to these structures, each fiber of $\mathfrak{u}$ has a natural MHS.

To complete the proof, we need to show that at each $P \in D$ there is a relative weight filtration of the fiber $u_P$ of $\overline{\mathfrak{u}}$ over $P$. First an easily verified fact. Suppose that $V$ is a PVHS over $C'$ of weight $m$. Let $M_\bullet$ be the monodromy weight filtration of its fiber $V_P$ over $P \in D$ shifted so that it is centered at $m$. Then if $A$ is a constant MHS, then the filtration $M_r(A \otimes V_P) := \sum_{i+j=r} W_i A \otimes M_j V_P$ defines a relative weight filtration of the fiber over $P \in D$ of the admissible variation of MHS $A \otimes V$.

From this it follows that the fiber over $P \in D$ of each $H^1(C', \mathbb{V}_\lambda)^* \otimes \mathbb{V}_\lambda$ has a relative weight filtration. Adding these implies that the fiber over $P \in D$ of each of the pro-variations $\mathfrak{u}_n$ has a relative weight filtration. Write the residue at $P \in D$ of $\nabla$ as the sum $N_P = N_0 + N_u$ of the residues of $\nabla_0$ and $\Omega$. The discussion above implies that the product of the weight filtrations on the fibers over $P$ of the $\mathfrak{u}_n$ defines a relative weight filtration for $N_0$ on the fiber $u_P$ of $\overline{\mathfrak{u}}$ over $P$. We have to show that this is also a relative weight filtration for $N$. To prove this, it suffices to show that $N_u \in W_{-2}u_P$. (See the definition of the relative weight filtration in [44].)

Let $t$ be a local holomorphic coordinate on $C$ centered at $P$. Then, near $P$, we can write

$$\Omega = N_0 + N_u \frac{dt}{t} + \text{a smooth } 1\text{-form with values in } \overline{\mathfrak{u}}$$

Since $\Omega^1 \in W_{-1}K^1(C, D; \mathfrak{u})$, and since $dt/t$ has weight 1, we see that $N_u \in W_{-2}u_P$, as required.

The last statement is a direct consequence of (3.4.2), the de Rham construction of the homomorphism in Section 4.2, and the fact that $\Omega \in F^{0}W_{-1}K^1(C, D; \mathfrak{u})$, which implies that $\theta_\Omega : H^0(C', \text{Hom}(\Lambda^j \mathfrak{u}, \mathbb{V})) \to K^*(C, D, \mathbb{V})$ preserves the Hodge filtration and satisfies

$$\theta_\Omega \left( W_m H^0(C', \text{Hom}(\Lambda^j \mathfrak{u}, \mathbb{V})) \right) \subseteq W_{m-j}K^j(C, D, \mathbb{V})$$

in degree $j$. The last ingredient is the Theorem of the Fixed Part, which implies that for each $x \in C'$, the restriction mapping

$$H^0(C', \text{Hom}(\Lambda^j \mathfrak{u}, \mathbb{V})) \to C(x, V_x)^R$$

is an isomorphism of MHS for all $x \in C'$. \hfill $\square$

---

13 This is equivalent to the statement that $\theta_\Omega$ is a filtration preserving dga homomorphism to $\text{Dec}_W K^j(C, D, \mathbb{V})$, where $\text{Dec}_W$ is Deligne’s shifting functor (with respect to the weight filtration), [11].
7.7. A MHS on completed path torsors. Here we give a brief description of how to extend the methods of the previous section to construct the canonical MHS on the coordinate ring $\mathcal{O}(\mathcal{G}_{x,y})$ of the relative completion of the path torsor $\Pi(C'; x, y)$ of $C'$ with respect to a polarized VHS $V$. Here $C'$ may be an orbifold of the form $\Gamma \backslash X$.

As in Section 7.6, write $C'$ as the quotient of a simply connected Riemann surface $X$ by a discrete group $\Gamma$ isomorphic to $\pi_1(C', x)$. Trivialize the pullback of each $u_n$ to $X$ using the flat sections and use this to trivialize the pullback of $u$ to $X$. Here, unlike in the previous section, it is useful to denote the common fiber of the trivialization by $u$ so that the pullback of $u$ to $X$ is $X \times u$. The fiber over $t \in X$ will be regarded as $u$ with a Hodge filtration $F_t^*$, that depends on $t$, and a weight filtration $W_t$ that does not. We can therefore identify $\text{Hom}^{\text{cts}}(u_s, u_t)$ with $\text{End}^{\text{cts}}u$. The Hodge and weight filtrations induced from those on $\text{Hom}^{\text{cts}}(u_s, u_t)$ induce Hodge and weight filtrations on $\text{Hom}^{\text{cts}}(u_s, u_t)$.

For $s, t \in X$, set $U_{s,t}$ be the subscheme of $\text{Isom}^{\text{cts}}(u_s, u_t)$ that corresponds to the subgroup $U := \text{exp } u$ of $\text{Aut } u$. It is a pro-algebraic variety. Denote the subspace of $\text{Hom}^{\text{cts}}(u_s, u_t)$ that corresponds to the image of $U \in \text{End}(u)$, $u \mapsto \{v \mapsto uv\}$ by $U_{s,t}$. The coordinate ring of $U_{s,t}$ is $\mathcal{O}(U_{s,t}) \cong \text{Hom}^{\text{cts}}(U_{s,t}, \mathcal{C})$. It has natural Hodge and weight filtrations induced from those on $\text{Hom}^{\text{cts}}(u_s, u_t)$.

The pullback connection is $d + \Omega$, where $\Omega \in E^1(X) \otimes u$. Since the structure group of this connection is $\mathcal{U}$, the parallel transport map $T_{s,t} : u_s \to u_t$ lies in $U_{s,t}$.

As in Section 5, we choose a fundamental domain $D$ of the action of $\Gamma$ on $X$. Denote the unique lift of $z \in C'$ to $D$ by $\tilde{z}$. For each homotopy class of paths in $C'$ from $x$ to $y$ one has $\gamma \in \Gamma$ and a homotopy class $c_\gamma$ of paths from $\tilde{x}$ to $\gamma \tilde{y}$. Parallel transport defines a function

$$\Theta_{x,y} : \Pi(C'; x, y) \to U_{x,y} \times R_{x,y} \cong \mathcal{G}_{x,y}$$

by $(\gamma, c_\gamma) \mapsto (T(c_\gamma)^{-1}, \rho_{x,y}(\gamma))$. This is the relative completion of $\Pi(C'; x, y)$.

The isomorphism

$$\mathcal{O}(\mathcal{G}_{x,y}) \cong \mathcal{O}(U_{x,y}) \otimes \mathcal{O}(R_{x,y})$$

induces Hodge and weight filtrations on the coordinate ring of $\mathcal{G}_{x,y}$. It also has a natural $\mathbb{Q}$-structure as relative completion is defined over $\mathbb{Q}$ and behaves well under base change from $\mathbb{Q}$ to $\mathbb{C}$.

The following theorem generalizes Theorems 7.14 and 7.16. It is proved using a similar arguments. A more general version of all but the last statement is proved in [16, §12–13].

**Theorem 7.17.** These Hodge and weight filtrations define a MHS on $\mathcal{O}(\mathcal{G}_{x,y})$, making it a ring in the category of ind-mixed Hodge structures. This MHS coincides with the one constructed in [16]. It has the property that if $x, y, z \in X$, then the maps $\mathcal{G}_{x,y} \to \mathcal{G}_{y,x}$ and $\mathcal{G}_{x,y} \times \mathcal{G}_{y,z} \to \mathcal{G}_{x,z}$ induced by inverse and path multiplication, respectively, induce morphisms of MHS

$$\mathcal{O}(\mathcal{G}_{x,z}) \to \mathcal{O}(\mathcal{G}_{x,y})$$

and

$$\mathcal{O}(\mathcal{G}_{y,z}) \to \mathcal{O}(\mathcal{G}_{x,y}) \otimes \mathcal{O}(\mathcal{G}_{y,z})$$.

In addition the local system $\mathcal{G}_{x,y}$ over $C'$ whose fiber over $x, y$ is $\mathcal{O}(\mathcal{G}_{x,y})$ is an Ind object of the category of admissible variations of MHS over $C'$. 
7.8. **Tangential base points and limit MHSs.** Theorem 7.16 implies that for each choice of a non-zero tangent vector \( \bar{v} \) of \( C \) at \( P \in D \), there is a limit MHS on the fiber \( u_P \) of \( \overline{u} \) at \( P \). We will denote this MHS by \( u_{\bar{v}} \). It is natural to think of it as a MHS on the unipotent radical of the relative completion of the fundamental group \( \pi_1(C', \bar{v}) \) of \( C' \) with (tangential) base point \( \bar{v} \).

More generally, we consider path torsors between tangential base points. We first recall the definition from [12] of the torsor of paths \( \Pi(C'; \bar{v}, \bar{w}) \). Here \( P, Q \in D \) and \( \bar{v}, \bar{w} \in T_P C, \bar{w} \in T_Q C \) are non-zero tangent vectors. Elements of \( \Pi(C; \bar{v}, \bar{w}) \) are homotopy classes of piecewise smooth paths \( \gamma : I \to C \) satisfying

(i) \( \gamma(0) = P, \gamma(1) = Q \),

(ii) \( \gamma(t) \in C', \) when \( 0 < t < 1 \),

(iii) \( \gamma'(0) = \bar{v} \) and \( \gamma'(1) = -\bar{w} \).

This definition can be modified to define \( \Pi(C; \bar{v}, x) \) and \( \Pi(C; x, \bar{w}) \) when \( x \in C' \). One defines \( \pi_1(C', \bar{v}) = \Pi(C', \bar{v}, \bar{v}) \). For any 3 base points (tangential or regular) \( b, b', b'' \), there are composition maps

\[
\Pi(C'; b, b') \times \Pi(C'; b', b'') \to \Pi(C'; b, b'').
\]

7.8.1. **The MHS on \( u_{\bar{v}} \).** Suppose that \( P \in D \) and that \( \bar{v} \) is a non-zero tangent vector of \( C \) at \( P \). The complex vector space underlying the limit MHS on \( u_{\bar{v}} \) is the fiber \( u_P \) of \( \overline{u} \) over \( P \). Its Hodge and weight filtrations \( F^* \) and \( W_* \) are the restrictions to \( u_P \) of the Hodge and weight filtrations of \( \overline{u} \) that were constructed above. There is also the relative weight filtration \( M_* \) of \( u_P \), which was constructed in the proof of Theorem 7.16. These data depend only on \( P \) and not on \( \bar{v} \).

To construct the \( \mathbb{Q} \)-structure, choose a local holomorphic coordinate \( t : \Delta \to \mathbb{C} \) on \( C \) centered at \( P \) with the property that \( \bar{v} = \partial/\partial t \). Then there is a unique trivialization \( \overline{u}_{\bar{v}} \) of \( \overline{u} \) over \( \Delta \) such that (1) the trivialization is the identity on the fiber \( u_P \) over \( P \), (2) \( \Delta \cap D = \{ P \} \), and (3) \( \nabla = d + N_P dt/t \), where \( N_P \) is the residue of \( \nabla \) at \( P \). This trivialization allows us to identify fibers of \( u \) over points near \( P \) with \( u_P \). Note that this identification depends on the choice of the local coordinate \( t \).

For \( t \in \Delta \), the \( \mathbb{Q} \)-structure on \( u_P \) corresponding to \( t\bar{v} \) is simply the \( \mathbb{Q} \)-structure on \( u_p \) obtained by identifying \( u_P \) with the fiber \( u_t \) of \( u \) over \( t \in \Delta \) and taking the \( \mathbb{Q} \)-structure to be that of \( u_t \). The \( \mathbb{Q} \)-structure corresponding to \( \bar{v} \) is

\[
u_{\bar{v}, \bar{Q}} := t^{N_P} \nu_{t, \bar{Q}}.
\]

That is, it is the unique \( \mathbb{Q} \)-structure on \( u_P \) such that

\[
u_{t, \bar{Q}} := t^{-N_P} \nu_{t, \bar{Q}}.
\]

for all \( t \in \mathbb{C}^* \). Although the trivialization above depends on the choice of the local coordinate \( t \), the \( \mathbb{Q} \)-structure on \( u_P \) corresponding to \( \bar{v} \) depends only on \( \bar{v} \) the tangent vector \( \bar{v} \).
With a little more effort, one can construct the limit MHS on \( \mathcal{O}(G_{\vec{v}}) \). Full details will appear in [25]. As in the case of cohomology, where periods of limit MHSs can be computed by regularizing integrals, the periods of the limit MHS on \( u_{\vec{w}} \) are regularized iterated integrals. A detailed discussion of how to regularize iterated integrals with twisted coefficients can be found in [26].

7.8.2. Limit MHS on completed path torsors. Similarly, one can construct the limit MHS on \( \mathcal{O}(G_{x,\vec{w}}) \) and \( \mathcal{O}(G_{\vec{v},\vec{w}}) \), etc. Full details will appear in [25].

8. Completed Path Torsors and Admissible Variations of MHS

Here we state two results that relate the Hodge theory of relative completion of fundamental groups and path torsors to admissible variations of MHS. These are special cases of results in [25].

Let \( C, D \) and \( C' = C - D \) be as above. Let \( V \) be a PVHS over \( C' \) and \( R_x \) the Zariski closure of the monodromy representation \( \rho_x : \pi_1(C', x) \to \text{Aut} V_x \). Let \( G_x \) be the completion of \( \pi_1(C', x) \) with respect to \( \rho_x \). For base points (regular or tangential) \( b, b' \) of \( C' \), let \( G_{x,y} \) denote the relative completion of \( \Pi(C'; b, b') \).

Denote by \( \text{MHS}(C', V) \) the category of admissible VMHS \( A \) over \( C' \) with the property that the monodromy representation \( \pi_1(C', x) \to \text{Aut}(A_x) \) factors through \( \rho_x \). This condition implies that the monodromy representation

\[
\pi_1(C', x) \to \text{Aut}(A_x)
\]

factors through \( \pi_1(C', x) \to G_x \).

**Theorem 8.1.** For all variations \( A \) in \( \text{MHS}(C', V) \) and all base points \( b, b' \) (possibly tangential) of \( C' \) the parallel transport mapping

\[
A_b \to A_{b'} \otimes \mathcal{O}(G_{b,b'})
\]

induced by \( A_b \times \Pi(C'; b, b') \to A_{b'} \) is a morphism of MHS. When \( b \) or \( b' \) is tangential, then the monodromy preserves both the weight filtration \( W_\bullet \) and the relative weight filtration \( M_\bullet \).

A representation \( G_b \to \text{Aut} E \) of \( G_b \) on a MHS \( A \) is a homomorphism for which the action

\[
A \to A \otimes \mathcal{O}(G_b)
\]

is a morphism of MHS and preserves both \( M_\bullet \) and \( W_\bullet \) if \( b \) is tangential. The previous result implies that taking the fiber at \( b \) defines a functor from \( \text{MHS}(C', V) \) to the category \( \text{HRep}(G_b) \) of Hodge representations of \( G_b \).

The following theorem follows from Theorem 7.14 by a tannakian argument. Full details will be given in [25].

**Theorem 8.2.** For all base points \( b \) of \( C' \), the “fiber at \( b \)” functor \( \text{MHS}(C', V) \to \text{HRep}(G_b) \) is an equivalence of categories.

Rather than sketching a proof of this result, we present several examples in Section 13.
Part 2. Completed Path Torsors of Modular Curves

In this part, we apply the general constructions of the first part to explore the relative completions of modular groups, mainly in the case of the full modular group \( SL_2(\mathbb{Z}) \). Throughout we use the following notation.

Suppose that \( \Gamma \) is a finite index subgroup of \( SL_2(\mathbb{Z}) \). The associated modular curve \( X_\Gamma \) is the quotient \( \Gamma \backslash \mathfrak{h} \) of the upper half plane by \( \Gamma \). It is a smooth affine curve when \( \Gamma \) is torsion free. When \( \Gamma \) has torsion, it will be regarded as an orbifold as follows: Choose a finite index, torsion free normal subgroup \( \Gamma' \) of \( \Gamma \). Set \( G = \Gamma / \Gamma' \).

Then \( X_\Gamma \) is the orbifold quotient of \( X_{\Gamma'} \) by \( G \). To work on the orbifold \( X_\Gamma \), one can work either \( G \)-equivariantly on \( X_{\Gamma'} \) or \( \Gamma \)-equivariantly on \( \mathfrak{h} \).

The (orb) curve \( X_\Gamma \) can be completed to a smooth (orb) curve by adding the finite set \( D := \Gamma \backslash \mathbb{P}^1(\mathbb{Q}) \) of “cusps”. Denote the compactified curve by \( \overline{X}_\Gamma \). When \( \Gamma = SL_2(\mathbb{Z}) \), the modular curve \( X_\Gamma \) is the moduli space \( M_{1,1} \) of elliptic curves and \( \overline{X}_\Gamma \) is \( \overline{M}_{1,1} \), its the Deligne-Mumford compactification, which is obtained by adding a single cusp.

If \( P \in D \) is in the orbit of \( \infty \in \mathbb{P}^1(\mathbb{Q}) \), then

\[
\Gamma \cap \begin{pmatrix} 1 & \mathbb{Z} \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & n \mathbb{Z} \\ 0 & 1 \end{pmatrix},
\]

for some \( n \geq 1 \). A punctured neighbourhood of \( P \) in \( X_\Gamma \) is the quotient of \( \{ \tau \in \mathbb{C} : \text{Im}(\tau) > 1 \} \) by this group. This is a punctured disk with coordinate \( e^{2\pi i \tau} \).

The Variation of Hodge Structure \( \mathbb{H} \)

9. The Local System \( \mathbb{H} \). The universal elliptic curve \( f : \mathcal{E} \to X_\Gamma \) over \( X_\Gamma \) is the quotient of \( \mathbb{C} \times \mathfrak{h} \) by \( \Gamma \ltimes \mathbb{Z}^2 \), which acts via

\[
(m, n) : (z, \tau) \mapsto (z + (m \ n) \begin{pmatrix} \tau \\ 1 \end{pmatrix}, \tau)
\]

and \( \gamma : (z, \tau) \mapsto ((c\tau + d)^{-1}z, \gamma \tau) \), where

\[
\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma.
\]

When \( \Gamma \) is not torsion free, it should be regarded as an orbifold family of elliptic curves.

The local system \( \mathbb{H} \) over \( X_\Gamma \) is \( R^1f_*\mathcal{O} \). When \( \Gamma \) is torsion free, this is the local system over \( X_\Gamma \) with fiber \( H^1(f^{-1}(x), \mathcal{O}) \) over \( x \). It is a polarized variation of HS of weight 1. Since Poincaré duality induces an isomorphism

\[
H_1(E) \cong H^1(E)(1)
\]

for all elliptic curves \( E \), the polarized variation \( \mathbb{H}(1) \) of weight \(-1\) is the local system over \( X_\Gamma \) whose fiber over \( x \) is \( H_1(f^{-1}(x), \mathcal{O}) \). The polarization is the intersection pairing. Denote the corresponding holomorphic vector bundle \( \mathbb{H} \otimes \mathcal{O}_{X_\Gamma} \) by \( \mathcal{H} \). Its Hodge filtration satisfies

\[
\mathcal{H} = F^0\mathcal{H} \supset F^1\mathcal{H} \supset F^2\mathcal{H} = 0.
\]

The only interesting part is \( F^1\mathcal{H} \).
In general we will work with the pullback $\mathbb{H}_h$ of $\mathbb{H}$ to $h$. Its fiber over $\tau \in h$ is $H^1(E_\tau, \mathbb{Z})$, where 

$$E_\tau := \mathbb{C}/\Lambda_\tau$$

and $\Lambda_\tau := \mathbb{Z} \oplus \mathbb{Z}\tau$.

Denote the basis of $H_1(E_\tau, \mathbb{Z})$ corresponding to the elements 1 and $\tau$ of $\Lambda_\tau$ by $a, b$. Denote the dual basis of $H^1(E_\tau)$ by $\tilde{a}, \tilde{b}$. These trivialize $\mathbb{H}_h$.

If we identify $H^1(E_\tau)$ with $H^1(E_\tau)$ via Poincaré duality, then

$$\tilde{a} = -b$$

and

$$\tilde{b} = a.$$

We regard these as sections of $H_h$.

For each $\tau \in h$, let $\omega_\tau \in H^0(E_\tau, \Omega^1)$ be the unique holomorphic differential that takes the value 1 on $a$. It spans $F_{\mathbb{H}} H^1(E_\tau)$. In terms of the framing, it is given by

$$(9.1) \quad \omega_\tau = a + \tau b = \tau a - b = (a - b) \begin{pmatrix} \tau \\ 1 \end{pmatrix}.$$ 

The map $\omega : \tau \mapsto \omega_\tau$ is a thus holomorphic section of $\mathcal{H}_h := \mathbb{H}_h \otimes \mathcal{O}_h$ whose image spans $F_1 \mathcal{H}_h$.

**Lemma 9.2.** For all $\gamma \in \Gamma$,

(i) $\gamma : (a - b) \mapsto (a - b) \gamma$,

(ii) the section $\omega$ of $\mathcal{H}_h$ satisfies $(1 \otimes \gamma) \omega = (c\tau + d)(\gamma^{\star} \otimes 1)\omega$.

**Proof.** Let $\gamma = \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix}$. Regard $a$ and $b$ as sections of $\mathbb{H}_h$. Denote the values of $a$ and $b$ at $\tau$ by $a, b$ and at $\gamma(\tau)$ by $a', b'$. Then (cf. Figure 3)

$$a' = c\tau + d$$

and

$$b' = a\tau + b.$$

Thus

$$(a' - b') = (a - b) \begin{pmatrix} d \\ -c \\ -b \\ a \end{pmatrix} = (a - b) \gamma^{-1}.$$ 

The second assertion now follows:

$$(1 \otimes \gamma) \omega = (a - b) \gamma \begin{pmatrix} \tau \\ 1 \end{pmatrix} = (c\tau + d)(a - b) \begin{pmatrix} \gamma \tau \\ 1 \end{pmatrix} = (c\tau + d)(\gamma^{\star} \otimes 1)\omega.$$ 

$\square$
Define \( w \) to be the section

\[
40 \quad \text{Define } w \text{ to be the section (9.3)}
\]

of \( H_h \). Since \( \langle w, a \rangle = 2\pi i (\tau a - b) \), \( w, a \) is a framing of \( H_h \). The sections \( a \) and \( w \) trivialize \( H_h \) over \( h \). As we shall see below, this trivialization is better suited to computing limit MHSs. The following computation is immediate. The proof of an equivalent formula can be found in [21, Ex. 3.4].

**Corollary 9.4.** The factor of automorphy associated to the trivialization

\[
H_h \cong (Ca + Cw) \times h
\]

of the pullback of \( H \) to \( h \) is

\[
\text{That is, the action of } SL_2(Z) \text{ on } (Ca + Cw) \times h \text{ is}
\]

\[
\gamma : (a, \tau) \mapsto ((c\tau + d)^{-1} + (c/2\pi i)w, \gamma \tau) \quad \text{and} \quad \gamma : (w, \tau) \mapsto ((c\tau + d)w, \gamma \tau).
\]

The sections \( a \) and \( w \) of \( H_h \) are both invariant under \( \tau \mapsto \tau + 1 \). They therefore descend to sections of the quotient \( H_{D^*} \rightarrow D^* \) of \( H_h \rightarrow h \) by \( \left( \begin{array}{cc} 1 & Z \\ 0 & 1 \end{array} \right) \). They trivialize \( H_{D^*} \). The vector bundle

\[
\text{Hodge bundle } F_1 H_{D^*} \text{ extends to the sub-bundle } O_D w \text{ of } H_{D^*}.
\]

We now compute the limit MHSs \( H_{\bar{v}}(1) \) on \( H(1) \) at \( q = 0 \) associated to the non-zero tangent vector \( \bar{v} = z \partial / \partial q \). It will have integral lattice \( H_z \), complexification \( H \) and \( F^0 H \) defined by

\[
H_z = Z a \oplus Z b, \quad H = Ca \oplus Cw \quad \text{and} \quad F^0 H = Cw \subset H.
\]

To specify the MHS, we give an isomorphism \((H_z) \otimes \mathbb{C} \cong H\), which will depend on the tangent vector \( \bar{v} \).

**Proposition 9.6.** The \( \mathbb{Z} \)-MHS \( H_{\bar{v}}(1) \) on \( H(1) \) that corresponds to the non-zero tangent vector \( \bar{v} = z \partial / \partial q \) is the MHS determined by the linear isomorphism \((H_z) \otimes \mathbb{C} \cong H\) given by

\[
(a \quad w) = (a \quad -b) \left( \begin{array}{c} 1 \\ 0 \end{array} \right) \log z \left( \begin{array}{c} \frac{1}{2\pi i} \end{array} \right).
\]
It is the extension of $\mathbb{Z}$ by $\mathbb{Z}(1)$ that corresponds to $z \in \mathbb{C}^*$ under the standard isomorphism $\text{Ext}^1_{\text{MHS}}(\mathbb{Z}, \mathbb{Z}(1)) \cong \mathbb{C}^*$. It splits if and only if $\vec{v} = \partial / \partial q$.

**Proof.** Most of this is proved above. The integral lattice of $H_{\partial / \partial q}$ is computed using the standard prescription and the fact that the value of $w$ at $z \in D^*$ is

$$w(z) = \log z \, a + 2\pi i (-b),$$

which follows from (9.1). \qed

This result can also be stated by saying that the limit MHS on $H$ of the variation $H$ associated to $z \partial / \partial q$ is the extension of $\mathbb{Z}(-1)$ by $\mathbb{Z}(0)$ corresponding to $z \in \mathbb{C}^* \cong \text{Ext}^1_{\text{MHS}}(\mathbb{Z}(-1), \mathbb{Z}(0))$.

**Remark 9.7.** Note that if $\vec{v} \in \mathbb{Q} \times \partial / \partial q$, then $H_{\vec{v}}(1)$ splits as an extension of $\mathbb{Q}$ by $\mathbb{Q}(1)$ if and only if $\vec{v} = \pm \partial / \partial q$. These are also the only two tangent vectors of the cusp $q = 0$ of $\mathbb{M}_{1,1}$ that are defined over $\mathbb{Z}$ and remain non-zero at every prime $p$. For this reason it is natural to identify the fiber $H$ of $\mathbb{H}$ over $q = 0$ with $H_{\partial / \partial q}$. In particular, $w = -2\pi i b$.

These considerations suggest a natural choice of Cartan subalgebra of $\mathfrak{sl}(H)$ and the positive root vectors. Namely, the Cartan is the one that acts diagonally with respect to the isomorphism

$$H_{\pm \partial / \partial q} \otimes \mathbb{Q} = \mathbb{Q}(0) \oplus \mathbb{Q}(1) = \mathbb{Q} a \oplus \mathbb{Q} b$$

The natural choice of a positive weight vector is the one with positive Hodge theoretic weight. Since $b$ has Hodge weight 0 and $a$ has weight $-2$, the natural choice of positive roots vectors in $\mathfrak{sl}(H)$ is $\mathbb{Q} b / \partial / a$. With this choice of Cartan subalgebra, there are two natural choices of symplectic bases of $H_\mathbb{Q}$. Namely $a, b$ and $-b, a$. Because of formula (i) in Lemma 9.2, which is dictated by the standard formula for the action of $\text{SL}_2(\mathbb{Z})$ on $\mathfrak{h}$, we will use the basis $-b, a$. This choice determines corresponding isomorphisms $\mathfrak{sl}(H) \cong \mathfrak{sl}_2$ and $\text{SL}(H) \cong \text{SL}_2$. With respected to the above choice of Cartan subalgebra, $\mathbb{Q} b$ has weight 1 and $\mathbb{Q} a$ has weight $-1$.

## 10. Representation Theory of $\text{SL}_2$

This is a quick review of the representation theory of $\mathfrak{sl}_2$ and $\text{SL}_2$. Much of the time, $\text{SL}_2$ will be $\text{SL}(H)$, where $H = H_{\partial / \partial q}$ is the fiber of $\mathbb{H}$ over $\partial / \partial q$. As pointed out above, this has a natural basis, which leads us to a natural choice of Cartan and Borel subalgebras, which we make explicit below.

Let $F$ denote $\mathbb{Q}$, $\mathbb{R}$ or $\mathbb{C}$. Let $V$ be a two dimensional vector space over $F$ endowed with a symplectic form (i.e., a non-degenerate, skew symmetric bilinear form)

$$\langle \ , \ \rangle : V \otimes V \rightarrow F.$$ The choice of a symplectic basis $v_1, v_2$ of $V$ determines actions of $\text{SL}_2(F)$ and $\mathfrak{sl}_2(F)$ on $V$ via the formula

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} : (v_2 \ v_1) \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \mapsto (v_2 \ v_1) \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$

where $x_1, x_2 \in F$, and isomorphisms $\text{SL}_2 \cong \text{SL}(V)$ and $\mathfrak{sl}_2 \cong \mathfrak{sl}(H)$.\[\text{\textcopyright } \text{American Mathematical Society} \text{\textregistered } 2000\text{\textperiodcentered}
We will fix the choice of Cartan subalgebra of $\mathfrak{sl}_2$ to be the diagonal matrices. This fixes a choice of Cartan subalgebra of $\mathfrak{sl}(V)$. We will take $v_1$ to have $\mathfrak{sl}_2$ weight $-1$ and $v_2$ to have $\mathfrak{sl}_2$-weight $+1$. The element

$$\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$$

do of $\mathfrak{sl}_2$ corresponds to $v_2 \partial/\partial v_1 \in \mathfrak{sl}(V)$ and has weight $-2$. Denote it by $e_0$.

Isomorphism classes of irreducible representations of $\text{SL}(V)$ correspond to non-negative integers. The integer $n \in \mathbb{N}$ corresponds to the $n$th symmetric power $S^n V$ of the defining representation $V$. To distinguish distinct but isomorphic representations of $\text{SL}_2$, we use the notation

$$S^n(e) := \{ e_0^i \cdot e : e_0^{n+1} \cdot e = 0 \}$$

to denote the $\text{SL}_2$-module with highest weight vector $e$ of weigh $n$.

For example, motivated by the discussion in Remark 9.7, we will typically work in the following situation:

(i) $V = H$ and $\langle , \rangle$ is the intersection pairing,

(ii) $v_1 = -b$ and $v_2 = a$, so that $b$ has $\mathfrak{sl}_2$ weight $+1$ and $a$ has $\mathfrak{sl}_2$ weight $-1$,

(iii) $S^n H = S^n(b^n)$,

(iv) $e_0 = -a \frac{\partial}{\partial b}$, which has $\mathfrak{sl}_2$ weight $-2$. It is also $-2\pi i$ times the residue at $q = 0$ of the connection $\nabla_0$ on $\mathbb{H}$.

Note that the weight filtration

$$0 = M_{-n-1} S^n H \subset M_{-n} S^n H \subset \cdots \subset M_{n-1} S^n H \subset M_n S^n H = S^n H$$

associated to the nilpotent endomorphism $e_0$ of $S^n H$ is

$$M_m S^n H = \{ \text{vectors of } \mathfrak{sl}_2\text{-weight } \leq m \} = \text{span} \{ a^{n-j} b^j : 2j - n \leq m \},$$

so that $M_{2r-n} S^n H = M_{2r-n+1} S^n H = \ker e_0^{r+1} = \text{im} e_0^{n-r}$. This implies that

$$\text{Gr}^M_{2n} S^n H = S^n H/\text{im} e_0 \cong \mathbb{Q}(-n).$$

It is generated by the highest weight vector $b^n$.

11. Modular Forms and Eichler-Shimura

Suppose that $\Gamma$ is a finite index subgroup of $\text{SL}_2(\mathbb{Z})$. Recall that a holomorphic function $f : \mathbb{H} \to \mathbb{C}$ is a modular form of weight $m$ for $\Gamma$ if

(i) $f(\gamma \tau) = (c\tau + d)^m f(\tau)$ for all $\gamma \in \Gamma$. This implies that $f$ has a Fourier expansion $\sum_{k = -\infty}^{\infty} a_k q^{k/m}$ for some $n \geq 1$.

(ii) $f$ is holomorphic at each cusp $P \in \Gamma \setminus \mathbb{P}^1(\mathbb{Q})$. If, for example, $P = \infty$, this means that the coefficients $a_k$ of the Fourier expansion of $f$ at $P$ vanish when $k < 0$.

A modular form $f$ is a cusp form if it vanishes at each cusp — that is, its Fourier coefficients $a_k$ vanish for all $k \leq 0$.

Assume the notation of Section 10. For an indeterminate $e$ we have the $\text{SL}_2$-module $S^m(e)$ that is isomorphic to $H$. Denote the corresponding local system over $X_\Gamma$ by $S^m(e)$. As a local system, it is isomorphic to $S^m \mathbb{H}$. Lemma 7.1 implies that if $S^m(e)$ has the structure of a PVHS, then it is isomorphic to $S^m \mathbb{H}(r)$ for some $r \in \mathbb{Z}$.
For the time being, we will suppose that the PVHS $S^m(e)$ over $X_\Gamma$ has weight 1, so that it is an isomorphic copy of $S^m\mathbb{H}$. Define a function $v : \mathfrak{h} \to V$ by

$$v(\tau, e) := \exp(\tau e_0)e.$$

The discussion preceding Lemma 9.2 implies that $v(\tau, e)$ is a trivializing section of $F^m(S^m(e) \otimes \mathcal{O}_h)$.

**Lemma 11.1.** For all $\gamma \in SL_2(\mathbb{Z})$ we have $(c\tau + d)^m \gamma^* v = \gamma_* v$.

**Proof.** Write $e = b^m$, where $b \in H$. Then $\exp(\tau e_0) = (\exp(\tau e_0))_b^m$. So it suffices to consider the case $m = 1$. In this case $v(\tau, b) = (-a, b)(\tau, 1)^T$ and

$$(\gamma_* v)(\tau, b) = - (a - b) \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \tau \\ 1 \end{pmatrix} = -(c\tau + d) (a - b) \begin{pmatrix} \gamma^* \tau \\ 1 \end{pmatrix} = (\gamma^* v)(\tau, b).$$

\[ \square \]

For a modular form $f$ of $\Gamma$ weight $m + 2$ and an indeterminate $e$, define

$$\omega_f(e) = f(\tau)v(\tau, e)d\tau \in E^1(h) \otimes S^m(e).$$

A routine calculation shows that $\omega_f(e)$ is $\Gamma$ invariant in the sense that

$$(\gamma^* \otimes 1)\omega_f(e) = (1 \otimes \gamma)\omega_f(e).$$

It follows that

$$\omega_f(e) \in (E^1(h) \otimes S^m(e))^\Gamma \cong E^1(X_\Gamma, S^m(e)).$$

Since $\omega_f(e)$ is closed, it determines a class in $H^1(X_\Gamma, S^m(e))$. Its complex conjugate

$$\overline{\omega_f(e)} = \overline{f(\tau)v(\tau, e)}^m d\tau$$

also defines a class in $H^1(X_\Gamma, S^m(e))$.

Recall that $X_\Gamma = \overline{X_\Gamma} - D$, where $D = \Gamma \setminus \mathbb{P}^1(\mathbb{Q})$. And recall from Section 6 that $K^\bullet(\overline{X}, D; S^n(e))$ is Zucker’s mixed Hodge complex that computes the MHS on $H^\bullet(X_\Gamma, S^n(e))$. It is straightforward to check that:

**Proposition 11.2** (Zucker [48]). If $f$ is a modular form of $\Gamma$ of weight $m + 2$, then

$$\omega_f(e) \in F^{m+1}K^1(\overline{X}_\Gamma, D; S(e)).$$

If $f$ is cusp form, then $w_f(e) \in F^{m+1}W_mK^1(\overline{X}_\Gamma, D; S(e)).$

When $m > 0$ the exact sequence (6.3) from Section 6.4 becomes

(11.3)

$$0 \to W_{m+1}H^1(X_\Gamma, S^m(e)) \to H^1(X_\Gamma, S^m(e)) \to \bigoplus_{P \in D} (S^m V_P) / \text{im } N_P (-1) \to 0,$$

where $V_P$ denotes the fiber of the canonical extension of $S^m(e) \otimes \mathcal{O}_{X_\Gamma}$ to $C$ and $N_P$ the associated local monodromy operator. It is an exact sequence of MHS. Note that each $S^m V_P / \text{im } N_P$ is one dimensional and is isomorphic to $\mathbb{Q}(-m)$ by (10.2).

The following result is equivalent to Eichler-Shimura combined with the observations that

$$K^1(\overline{X}_\Gamma, D; S^m(e)) = W_{m+1}K^1(\overline{X}_\Gamma, D; S^m(e)) \quad \text{and} \quad F^{m+2}K^1(\overline{X}_\Gamma, D; S^m(e)) = 0.$$

This version was proved by Zucker in [48]. Denote the space of modular forms of $\Gamma$ of weight $k$ by $M_k(\Gamma)$ and the subspace of cusp forms by $M^0_k(\Gamma)$. 

Theorem 11.4 (Shimura, Zucker). If $\Gamma$ is a finite index subgroup of $\text{SL}_2(\mathbb{Z})$, then $H^1(X_\Gamma, \mathbb{S}^m(e))$ is spanned by the classes of modular forms. The only non-vanishing Hodge numbers $h^{p,q}$ occur when $(p,q) = (m+1,0)$, $(0,m+1)$ and $(m+1,m+1)$. The weight $m+1$ part is spanned by the classes of cusp forms and their complex conjugates. Moreover, the function that takes a modular form $f$ to the class of $\omega_f(e)$ induces an isomorphism

$$M_{m+2}(\Gamma) \cong F^{m+1}H^1(X_\Gamma, \mathbb{S}^m(e)).$$

The map that takes a cusp form $f$ to the class of its complex conjugate $\overline{\omega}_f(e)$ induces a conjugate linear isomorphism of $M^0_{k+2}(\Gamma)$ with the $(0,m+1)$ part of the Hodge structure $W_{m+1}H^1(X_\Gamma, \mathbb{S}^m(e))$.

When $\Gamma = \text{SL}_2(\mathbb{Z})$, there is only one cusp. It is routine to show that the cohomology with coefficients in $\mathbb{S}^m(e)$ vanishes when $m$ is odd. So for each $n > 0$ we have the exact sequence

$$0 \to W_{2n+1}H^1(M_{1,1}, \mathbb{S}^{2n}(e)) \to H^1(M_{1,1}, \mathbb{S}^{2n}(e)) \to \mathbb{Q}(-2n-1) \to 0$$

The class of the $1$-form $\omega_f(e)$ associated to the Eisenstein series $f = G_{2n+2}$ of weight $2n+2$ projects to a generator of $\mathbb{Q}(-2n-1)$. The MHS on $H^1(X_\Gamma, \mathbb{S}^{2n}(e))$ can be described in terms of modular symbols. We will return to this in Section 17.2.

11.1. Cohomology of congruence subgroups. Recall that a congruence subgroup of $\text{SL}_2(\mathbb{Z})$ is one that contains a principal congruence subgroup

$$\text{SL}_2(\mathbb{Z})[N] := \{ \gamma \in \text{SL}_2(\mathbb{Z}) : \gamma \equiv \text{identity mod } N \}.$$

When $\Gamma$ is a congruence subgroup, one has Hecke operators

$$T_p \in \text{End}_{\text{MHS}} H^1(X_\Gamma, \mathbb{S}^m\mathbb{H})$$

for each prime number $p$. Since the Hecke algebra (the algebra generated by the $T_p$) is semi-simple, $H^1(X_\Gamma, \mathbb{S}^m\mathbb{H}_\mathbb{Q})$ decomposes into simple factors. Each is a MHS.

For a normalized Hecke eigenform $f$ of $\Gamma$, let $K_f$ be the subfield of $\mathbb{C}$ generated by its Fourier coefficients. Since the restriction of $T_p$ to the cusp forms is self adjoint with respect to the Petersen inner product, its eigenvalues are real. Since this holds for all $p$, it implies that $K_f \subset \mathbb{R}$. Consequently, the smallest subspace $V_f$ of $H^1(X_\Gamma, \mathbb{S}^m\mathbb{H}_{K_f})$ whose complexification contains $\omega_f(e)$ is a $K_f$-sub HS of the MHS $H^1(X_\Gamma, \mathbb{S}^m\mathbb{H})$.

Denote by $M_f$ the smallest $\mathbb{Q}$-Hodge sub-structure of $H^1(X_\Gamma, \mathbb{S}^m\mathbb{H}_\mathbb{Q})$ with the property that $M_f \otimes K_f$ contains $V_f$. It is a sum of the Hodge structures $V_h$ of the eigenforms conjugate to $f$. Call two eigenforms $f$ and $h$ equivalent if $M_f = M_h$.

When $f$ is a normalized Eisenstein series the smallest sub-MHS of $H^1(X_\Gamma, \mathbb{S}^m\mathbb{H}_\mathbb{Q})$ that contains the corresponding cohomology class is one dimensional and spans a Tate MHS $\mathbb{Q}(-m-1)$.

Theorem 11.5. If $\Gamma$ is a congruence subgroup of $\text{SL}_2(\mathbb{Z})$, then the MHS Hodge structure on $H^1(X_\Gamma, \mathbb{S}^m\mathbb{H})$ splits. In particular, when $m > 0$, there is a canonical isomorphism

$$H^1(X_\Gamma, \mathbb{S}^m\mathbb{H}) \cong \bigoplus_f M_f \oplus \bigoplus_{p \in D} \mathbb{Q}(-m-1).$$
where \( f \) ranges over the equivalence classes of eigen cusp forms of weight \( m + 2 \).

As a real mixed Hodge structure

\[
H^1(X_\Gamma, S^m \mathbb{H}) \cong \bigoplus_{f \in \mathcal{B}_{m+2}(\Gamma)} V_f \oplus \bigoplus_{P \in D} \mathbb{R}(-m - 1).
\]

\( \bigoplus_{P \in D} \mathbb{R}(-m - 1) \)

Sketch of Proof. The splitting of the MHS on \( H^1(X_\Gamma, S^m \mathbb{H}) \) follows from the fact that each Hecke operator \( T_p \) is a morphism of MHS. The weight filtration splits because \( T_p \) acts on \( \text{Gr}^{W, m+1} \) with eigenvalues of modulus bounded by \( C_p^{1+m/2} \) and on \( \text{Gr}^{W, 2m+2} \) with eigenvalues of size \( O(p^{m+1}) \). (For \( \text{SL}_2(\mathbb{Z}) \) this is proved in [41]. See p. 94 and p. 106. For general \( \Gamma \) it follows from Deligne’s solution of the Weil Conjectures.) The \( V_f \) are the common eigenspaces of the \( T_p \) acting on \( W_{m+1} H^1(X_\Gamma, S^m \mathbb{H}) \). The \( M_f \) are their Galois orbits and are \( \mathbb{Q} \)-HS.

\[ \square \]

12. Hodge Theory of the Relative Completion of Modular Groups

Here we make the construction of the mixed Hodge structure on the unipotent radical of the completion of a modular group with respect to its inclusion into \( \text{SL}_2(\mathbb{Q}) \) explicit.

We retain the notation of previous sections: \( \Gamma \) is a finite index subgroup of \( \text{SL}_2(\mathbb{Z}) \), \( X_\Gamma = \Gamma \backslash \mathfrak{h} \) is the associated modular curve, \( D = \Gamma \backslash \mathbb{P}^1(\mathbb{Q}) \) is the set of cusps, and \( \overline{X_\Gamma} = X_\Gamma \cup D \) is its smooth completion. As in Section 9, \( H \) denotes the fiber over the unique cusp \( q = 0 \) of \( \overline{\mathcal{M}}_{1,1} \) of the canonical extension \( \overline{H} \) of the local system \( \mathbb{H} \). The pullback of \( \overline{H} \) along the quotient morphism \( \overline{X_\Gamma} \to \overline{\mathcal{M}}_{1,1} \) is the canonical extension of \( \mathbb{H} \otimes O_{X_\Gamma} \) to \( \overline{X_\Gamma} \), so that the fiber of \( \overline{H}_{X_\Gamma} \) over each \( P \in D \) is naturally isomorphic to \( H \).

Fix a base point \( x_o \) of \( X_\Gamma \). We allow \( x_o \) to be a non-zero tangent vector at a cusp \( P \in D \). Denote the completion of \( \pi_1(X_\Gamma, x_o) \) with respect its inclusion into \( \text{SL}_2(\mathbb{Q}) \) by \( \mathcal{G}_{x_o} \) and its prounipotent radical by \( U_{x_o} \). Their Lie algebras (and coordinate rings) have natural mixed Hodge structures. Recall that the polarized variation \( \mathbb{H} \) over \( X_\Gamma \) has weight 1. Denote its fiber over \( x_o \) by \( H_o \).

We also fix a lift \( \tau_o \) of \( x_o \) to \( \mathfrak{h} \). This determines an isomorphism \( \pi_1(X_\Gamma, x_o) \cong \Gamma \) and isomorphisms of \( \mathcal{G}_{x_o} \) and \( U_{x_o} \) with \( \Gamma \), the completion \( \mathcal{G} \) of \( \Gamma \) with respect to the inclusion \( \Gamma \to \text{SL}_2(\mathbb{Q}) \), and \( U \), its prounipotent radical.

12.1. General considerations. As pointed out in Section 3.4.2, \( u \) is free. So, up to a non-canonical isomorphism, it is determined by its abelianization \( H_1(u) \). By Theorem 7.14, implies that \( u \) has negative weights, so there is an exact sequence

\[
0 \to W_{-2} H_1(u)_{\text{nis}} \to H_1(u) \to \text{Gr}^{W, 1} u \to 0.
\]

of pro-MHS with \( \text{SL}_2 \) action. Eichler-Shimura (Thm. 11.4) and the computation (3.4) imply that the weight \(-1\) quotient comes from cusp forms:

\[
\text{Gr}^{W, -1} u = \prod_{m \geq 0} (W_{m+1} H^1(X_\Gamma, S^m \mathbb{H}))^* \otimes S^m H_o = \prod_{m \geq 0} IH^1(X_\Gamma, S^m \mathbb{H})^* \otimes S^m H_o.
\]

The exact sequence (6.3) implies that the weight \(< -1\) part

\[
W_{-2} H_1(u) = \tilde{H}_0(D; \mathbb{Q}(1)) \oplus \bigoplus_{P \in D} \prod_{m \geq 0} S^m H_o(m + 1)
\]

is a direct product of Hodge structures. Note that when \( x_o \) is a finite base point (i.e., \( x_o \in X_\Gamma \)), then \( S^m H_o(m + 1) \) has weight \(-m - 1\). If \( x_o \) is a tangent vector at
a cusp, then $S^m H_n(m + 1)$ has weight graded quotients $\mathbb{Q}(1), \mathbb{Q}(2), \ldots, \mathbb{Q}(m + 1)$.

In this case, $W_{-2} H_1(u)$ is mixed Tate.

The Manin-Drinfeld Theorem (Thm. 11.5) implies:

**Proposition 12.1.** If $\Gamma$ is a congruence subgroup of $\text{SL}_2(\mathbb{Z})$, then $H_1(u)$ is the product

$$H_1(u) \cong \prod_{r < 0} \text{Gr}_r^W H_1(u)$$

of its weight graded quotients in the category of pro-MHS with $\text{SL}_2$ action. □

12.2. **Hodge theory of congruence subgroups.** Now assume that $\Gamma$ is a congruence subgroup of $\text{SL}_2(\mathbb{Z})$. The first step in writing down a formal connection $\Omega \in K^1(\overline{X}_\Gamma, D; u)$ is to write down, for each $m > 0$, a form

$$\Omega_{1,m} \in \mathcal{F}^0 W_{-1}(K^1(\overline{X}_\Gamma, D; S^m \mathbb{H}) \otimes H^1(X_\Gamma, S^m \mathbb{H})^*)$$

that represents the identity $H^1(X_\Gamma, S^m \mathbb{H}) \to H^1(X_\Gamma, S^m \mathbb{H})$.

Since $\Gamma$ is a congruence subgroup, the Hecke algebra acts on the modular forms $M_m(\Gamma)$ of $\Gamma$ of weight $m$. Let $\mathfrak{H}_m$ be the set of normalized Hecke eigen cusp forms of weight $m \geq 2$. This is a basis of $M^0_m(\Gamma)$, the weight $m$ cusp forms. When $m > 2$, for each cusp $P \in D$, there is a normalized Eisenstein series $E_{m,P}(\tau)$ that vanishes at the other cusps. When $m = 2$, Eisenstein series give elements of $H^1(X_\Gamma, \mathbb{C})$ with non-zero residues at at least two cusps. Fix a cusp $P_0 \in D$. For each $P \in D' := D - \{P_0\}$, choose an Eisenstein series $E_{2,P} \tau$ that is non-zero at $P$ and vanishes at all other points of $D'$.

Now suppose that $m \geq 0$. Identify $S^m \mathbb{H}$ with $S^m(\mathfrak{b}^m)$. For each $f \in \mathfrak{H}_{m+2}$ we have the 1-forms $\omega_f(b^m)$ and $\overline{\omega}_f(b^m)$. When $m > 0$ (resp. $m = 0$) and $P \in D$ (resp. $P \in D'$) set

$$\psi_{m,P}(b^m) := \omega_{E_{m,P}}(b^m).$$

This will be viewed an element of $K^1(\overline{X}_\Gamma, D; S^m \mathbb{H})$ and of $E^1(b, S^m H)^\Gamma$. Then

$$\omega_f(b^m), \overline{\omega}_f(b^m) : f \in \mathfrak{H}_{m+2} \cup \{\psi_{m+2,P}(b^m) : (P \in D \text{ and } m > 0) \text{ or } (P \in D' \text{ and } m = 0)\}$$

is a subset of $K^1(\overline{X}_\Gamma, D; S^m \mathbb{H})$ that represents a basis of $H^1(X_\Gamma, S^m \mathbb{H})$. Let

$$\{u'_f, u''_f, u_{m+2,P} : f \in \mathfrak{H}_{m+2}, P \in D\}$$

be a basis of $H^1(X_\Gamma, S^m \mathbb{H})$ dual to the cohomology classes of the the closed forms (12.2). The Hodge types of $u'_f, u''_f$ and $u_{m+2,P}$ are $(-m - 1, 0), (0, -m - 1)$ and $(-m - 1, -m - 1)$, respectively.

Set

$$e'_f := b^m \otimes u'_f, e''_f := b^m \otimes \overline{\omega}_f, e_{m+2,P} = b^m \otimes u_{m+2,P}.$$

These are elements of $S^m H \otimes H^1(X_\Gamma, S^m \mathbb{H})^*$. Then

$$\omega_f(b^m) \otimes u'_f = \omega_f(e'_f), \overline{\omega}_f(b^m) \otimes u''_f = \overline{\omega}_f(e''_f),$$

and $\psi_{m+2,P}(b^m) \otimes u_{m+2,P} = \psi_{m+2,P}(e_{m+2,P})$.

All are elements of $K^1(\overline{X}_\Gamma, D; S^m \mathbb{H}) \otimes H^1(X_\Gamma, S^m \mathbb{H})^*$ and

$$\Omega_{1,m} = \sum_{f \in \mathfrak{H}_{m+2}} (\omega_f(e'_f) + \overline{\omega}_f(e''_f)) + \sum_P \psi_{m+2,P}(e_{m+2,P})$$
is a closed 1-form that represents the identity $H^1(X, S^m \mathbb{H}) \to H^1(X, S^m \mathbb{H})$. Here the second sum is over $P \in D$ when $m > 0$ and $P \in D'$ when $m = 0$.

**Lemma 12.5.** For each $m \geq 0$

$$\Omega_{1,m} \in F^0 W_{-1}(K^1(X, D; S^m \mathbb{H}) \otimes H^1(X, S^m \mathbb{H})).$$

**Proof.** Since the Hodge types of $u'_f$, $u''_f$ and $u_{m+2,P}$ are $(-m-1,0), (0,-m-1)$ and $(-m-1,-m-1)$, the definitions of the Hodge and weight filtrations of Zucker’s mixed Hodge complex $K^\bullet(X, D; S^m \mathbb{H})$ imply that

$$\omega_f(b^m) \in F^{m+1} W_m K^1(X, D; S^m \mathbb{H})$$

when $f \in \mathcal{B}_{m+2}$ and $\psi_{m+2,P}(b^m) \in F^{m+1} W_{m+1} K^1(X, D; S^m \mathbb{H})$ for each $P$. The result follows as $u'_f, u''_f$ and $u_{m+2,P}$ have Hodge types $(-m-1,0), (0,-m-1)$ and $(-m-1,-m-1)$, respectively. \qed

The Lie algebra $u$ of the pronilpotent radical $\mathcal{U}$ of the relative completion of $\Gamma$ is the free pronilpotent Lie algebra $u = \mathbb{L}(V)^\wedge$, where $V = \bigoplus_{m \geq 0} V_m$ and

$$V_m := H^1(X, S^m \mathbb{H})^* \otimes S^m H$$

$$= \begin{cases} H_1(X, \mathbb{C}) & m = 0, \\ \bigoplus_{f \in \mathcal{B}_{m+2}} (S^m(e'_f) \oplus S^m(e''_f)) \oplus \bigoplus_{P \in D} S^m(e_{m+2,P}) & m > 0. \end{cases}$$

It is a Lie algebra in the category of pro-representations of $\text{SL}_2$.

The 1-form

$$\Omega_1 := \sum_{m \geq 0} \Omega_{1,m} \in E^1(h) \otimes u$$

is $\Gamma$-invariant and represents the identity. It can thus be completed to a power series connection

$$\Omega \in F^0 W_{-1} K^1(X, D; u)$$

using the method described in Section 7, which determines the MHS on $u_x^\circ$.

Before discussing the case $\Gamma = \text{SL}_2(\mathbb{Z})$, note that since

$$S^m(e'_f) = \text{span}\{e'_0 \cdot e'_f : e'_0 \cdot e'_f = 0\}, \quad f \in \mathcal{B}_{m+2}$$

$$S^m(e''_f) = \text{span}\{e''_0 \cdot e''_f : e''_0 \cdot e''_f = 0\}, \quad f \in \mathcal{B}_{m+2}$$

$$S^m(e_{m+2,P}) = \text{span}\{e'_0 \cdot e_{m+2,P} : e'_0 \cdot e_{m+2,P} = 0\}, \quad P \in D,$$

$u$ is the free Lie algebra topologically generated by

$$\{e_{2,P} : P \in D'\} \cup \bigcup_{m \geq 0} \{e'_0 e'_f, e''_0 e'_f, e''_0 e_{m+2,P} : 0 \leq j \leq m, \ f \in \mathcal{B}_{m+2}, \ P \in D\}.$$

The Hodge and weight filtrations of $u$ are defined by giving $b \in H$ type $(1,0)$. The generators (12.3) thus have types given in Figure 4. So, for example, $e'_0 e'_f$ has type $(-1 - j, j)$. The Hodge and weight filtrations on the generators extend naturally to Hodge and weight filtrations on $u$.

The Hodge types on the $\mathfrak{sl}_2$ module with highest weight vectors $e'_f, e''_f, e_{m+2,P}$ are illustrated in Figure 5.
12.3. The case of $\text{SL}_2(\mathbb{Z})$. In this case, $X_\Gamma = M_{1,1}$, $C = \overline{M}_{1,1}$ and $D$ consists of a single point, which we shall denote by $P$. The modular parameter $q = e^{2\pi i \tau}$ is a local holomorphic coordinate on the orbifold $\overline{M}_{1,1}$ centered at $P$.

There are no modular forms for $\text{SL}_2(\mathbb{Z})$ of odd weight. Since there is a single cusp, there is a 1-dimensional space of Eisenstein series for each weight $2n \geq 4$.

The normalized Eisenstein series of even weight $2n$ is

$$G_{2n}(\tau) = \frac{1}{2} \frac{(2n-1)!}{(2\pi i)^{2n}} \sum_{\lambda \in \mathbb{Z} \setminus 2\mathbb{Z}} \frac{1}{\lambda^{2n}} = -\frac{B_{2n}}{4n} + \sum_{k=1}^{\infty} \sigma_{2n-1}(k)q^k.$$  

This has value $(2n-1)!\zeta(2n)/(2\pi i)^{2n}$ at the cusp $P$.\textsuperscript{14} The dual homology class $e_{2n,P}$ will be denoted by $e_{2n}$ and the form $\psi_{2n,P}$ by $\psi_{2n}$.

Later, we will use the tangent vector $\vec{v} := \partial/\partial q$ of $P$ as a base point.

13. VMHS associated to Modular Forms and their Period Maps

This section considers three related topics: relative Higher Albanese maps (which are related to period mappings of VMHS), Manin’s iterated Shimura integrals, and

\textsuperscript{14}Here $B_{2n}$ is the $2n$th Bernoulli number, $\zeta(s)$ is the Riemann zeta function and $\sigma_k(n)$ is the sum of the $k$th powers of the divisors of $n$.  

| $e_0$ | $e'_f$ | $e''_f$ | $e_{m+2,P}$ |
|-------|--------|------|-------------|
| Hodge type | $f \in \mathcal{B}_{m+2}$ | $f \in \mathcal{B}_{m+2}$ | $P \in D$ |
| $W$-weight | $(-1,1)$ | $(-1,0)$ | $(m,-m-1)$ | $(-1,-m-1)$ |
| $M$-weight | $0$ | $-1$ | $-1$ | $-m-2$ | $-2$ |

Figure 4. Hodge types of the generators of $u$.

Figure 5. Hodge numbers of $S^m(e'_f)$, $S^m(e''_f)$ and $S^m(e_{m+2,P})$. 

\begin{align*}
G_{2n}(\tau) &= \frac{1}{2} \frac{(2n-1)!}{(2\pi i)^{2n}} \sum_{\lambda \in \mathbb{Z} \setminus 2\mathbb{Z}} \frac{1}{\lambda^{2n}} = -\frac{B_{2n}}{4n} + \sum_{k=1}^{\infty} \sigma_{2n-1}(k)q^k. 
\end{align*} 

This section considers three related topics: relative Higher Albanese maps (which are related to period mappings of VMHS), Manin’s iterated Shimura integrals, and
the existence of extensions of VMHS coming from Hecke eigenforms. The construction of these extensions is a special case of the general technique for constructing admissible VMHS sketched in the proof of Theorem 8.2. Such extensions correspond to normal functions, so every Hecke eigen form produces a normal function.

13.1. Relative Albanese maps. This construction generalizes the non-abelian albanese manifolds of [27] from the unipotent case to the relative case. Although this discussion applies more generally, here we restrict to the case of modular curves.

Fix a base point \( \tau_0 \) of \( \mathfrak{h} \). (A natural choice is \( \tau_0 = i \).) Let \( \Gamma \) be a finite index subgroup of \( \text{SL}_2(\mathbb{Z}) \). Denote the image of \( \tau_0 \) in \( \overline{X}_\Gamma \) by \( x_0 \).

The choice of \( \tau_0 \) determines an isomorphism \( \Gamma \cong \pi_1(X_\Gamma,x_0) \). Let \( \mathcal{G}_o \) be the complex form of the relative completion of \( \pi_1(X_\Gamma,x_0) \). Let \( \mathcal{U}_o \) be its pronipotent radical, and let \( \mathfrak{g}_o, \mathfrak{u}_o \) be their Lie algebras. Since the bracket of \( \mathfrak{g}_o \) respects the Hodge filtration, \( F^0\mathfrak{g}_o \) is a subalgebra of \( \mathfrak{g}_o \). Denote the corresponding subgroup of \( \mathcal{G}_o \) by \( F^0\mathcal{G}_o \).

Let

\[
\Omega \in F^0W_{-1}K^1(\overline{X}_\Gamma,D;\mathfrak{u})
\]

be as above. Trivialize the pullback of \( \mathfrak{u} \) to \( \mathfrak{h} \) using the sections \( \{ e'_0 \cdot e'_f, e'_0 \cdot e''_f, e''_0 \cdot e_{2n} \} \):

\[
\mathfrak{u} \times \mathfrak{h} \to \mathfrak{h}.
\]

This trivializes both the Hodge and weight filtrations. It also fixes an isomorphism \( \mathcal{G}_x \cong \text{SL}(H_x) \times \mathcal{U}_x \). Denote the pullback of \( \Omega \) to \( \mathfrak{h} \) by

\[
\tilde{\Omega} \in (E^1(\mathfrak{h}) \otimes \mathfrak{u})^\Gamma.
\]

Since \( \tilde{\Omega} \) is integrable, the function \( F : \mathfrak{h} \to \mathcal{U}_o \times \text{SL}(H_o) \cong \mathcal{G}_o \) defined by

\[
F(\tau) := \left( 1 + \int_{\tau_0}^\tau \tilde{\Omega} + \int_{\tau_0}^\tau \tilde{\Omega} \tilde{\Omega} + \int_{\tau_0}^\tau \tilde{\Omega} \tilde{\Omega} \tilde{\Omega} + \cdots, \begin{pmatrix} v & v/u \\ 0 & v^{-1} \end{pmatrix} \right)
\]

where \( \tau = u + iv \), is well defined and smooth. It induces a function \( F : \mathfrak{h} \to \mathcal{G}_o/F^0\mathcal{G}_o \) which is equivariant with respect to the natural left \( \Gamma \)-actions on each.

**Proposition 13.1.** The function \( F : \mathfrak{h} \to \mathcal{G}_o/F^0\mathcal{G}_o \) is holomorphic. (That is, it is an inverse limit of holomorphic functions.)

**Proof.** Since \( \text{SL}(H_C)/F^0 \cong \mathbb{P}^1 \), and since the right hand matrix applied to \( \tau \) gives \( \tau \in \mathfrak{h} \subset \mathbb{P}^1 \), we need only check that the map is holomorphic in the first factor. Write \( \tilde{\Omega} = \tilde{\Omega}' + \tilde{\Omega}'' \), where \( \tilde{\Omega}' \) has type \((1,0)\) and \( \tilde{\Omega}'' \) has type \((0,1)\). Since \( \Omega \in F^0K^1(\overline{X}_\Gamma,D;\mathfrak{u}) \),

\[
\tilde{\Omega}'' \in E^{0,1}(\mathfrak{h}) \otimes F^0\mathfrak{u}.
\]

The fundamental theorem of calculus implies that \( F \) satisfies the differential equation \( d\tilde{F} = \tilde{F}\tilde{\Omega}' \) from which it follows that \( \partial\tilde{F} = \tilde{F}\tilde{\Omega}'' \). This implies the vanishing of \( \partial\tilde{F} \).

The projection \( \mathcal{G}_o \to \text{SL}(H_o,C) \) preserves the Hodge filtration and induces a holomorphic, \( \Gamma \)-invariant projection \( \mathcal{G}_o/F^0\mathcal{G}_o \to \text{SL}(H_o)/F^0 \cong \mathbb{P}^1 \). Then one has
the diagram
\[
\begin{array}{ccc}
(G_o/F^0G_o)|_h & \rightarrow & G_o/F^0G_o \\
\downarrow F & & \downarrow F \\
\SL(H_{x,C})/F^0 & \cong & \PP^1.
\end{array}
\]

Recall that our choices have fixed an isomorphism $G_o \cong \SL(H_o) \ltimes U_o$. The natural homomorphism corresponds to a non-abelian 1-cocycle $\Theta_o : \Gamma \rightarrow U_o(\QQ)$.

**Lemma 13.2.** The function $F : h \rightarrow G_o/F^0$ satisfies $F(\gamma \tau) = \Theta_o(\gamma)F(\gamma \tau)$ for all $\gamma \in \Gamma$.

**Proof.** The identification $G_o \cong \SL(H_o) \ltimes U_o$ induces an identification of $G_o/F^0$ with $U_o \times \PP^1$. If $c_o$ is a path from $\tau_o$ to $\gamma \tau_o$ and $c$ is a path from $\tau_o$ to $\tau$, then $c_o \cdot (\gamma \cdot c_o)$ is a path from $\tau_o$ to $\gamma \tau$. So

\[
F(\gamma \tau) = (\Theta_o(\gamma)T(c)^{-1}, \gamma \tau) = \Theta_o(\gamma)F(\tau),
\]

where $T^{-1}$ denotes $1 + \int \Omega + \int \bar{\Omega} + \cdots$. 

Let $U_{o,2}$ be the subgroup of $U_o$ that is generated by $\{ \Theta_o(\gamma) : \gamma \in \Gamma \}$. Let $G_{o,2}$ be the subgroup of $G_o \cong \SL(H_o) \cong U_o$ that corresponds to $\SL(H_{o,2}) \ltimes U_{o,2}$. The previous result implies that $F(\gamma \tau)$ and $\gamma F(\tau)$ lies in the same left $U_{o,2}$ orbit.

The **universal relative albanese manifold** of $X_\Gamma$ is defined by

\[
\mathcal{A}_\Gamma = U_{o,2}\backslash ((G_o/F^0G_o)|_h).
\]

There is a natural quotient mapping to $X_\Gamma$. Taking the quotient of the left-hand map of the previous diagram by $\Gamma$ gives the **universal non-abelian Albanese map**

\[
\mathcal{A}_\Gamma \rightarrow X_\Gamma.
\]

The fiber over $x_o \in X_\Gamma$ is isomorphic to $U_{o,2}\backslash U_o/F^0$.

**Remark 13.3.** For each finite dimensional quotient $G_\alpha$ of $G_o$ in the category of groups with a MHS, one can define

\[
\mathcal{A}_\alpha = G_{o,2}\backslash ((G_o/F^0G_o)|_h).
\]

Since $G_o$ is the inverse limit of the $G_\alpha$, $\mathcal{A}_\Gamma = \varprojlim \mathcal{A}_\alpha$. The reduction of the section $F$ is a holomorphic section $F_o$ of this bundle. In particular, when $\Gamma$ is a congruence subgroup, by taking $G_\alpha$ to be the quotient

\[
0 \rightarrow \hat{M}_f \otimes S^nH_o \rightarrow G_n \rightarrow \SL(H_o) \rightarrow 1
\]

where $M_f$ is the smallest $\QQ$-sub HS of $H^1(X_\Gamma, S^n\HH)$ that contains $\omega_f(e)$ and $\hat{M}_f$ its dual, we see that to each $f \in \mathcal{B}_{n+2}(\Gamma)$, there is a bundle over $X_\Gamma$ with fiber over $x \in X_\Gamma$ the intermediate jacobian

\[
\Ext^1_{\text{MHS}}(\ZZ, \hat{M}_{f,2} \otimes S^nH_{x,Z})
\]

with a holomorphic section. We will see below that this is a normal function which is the period mapping of an extension of $\QQ$ by $\hat{M}_f \otimes S^n\HH$. When $\Gamma$ is a congruence subgroup, each Eisenstein series determines a normal function that corresponds to an extension of $\ZZ$ by $S^n\HH(n + 1)$.
The coefficients of $F$ are holomorphic functions on $\mathfrak{h}$ which can be realized as periods of admissible variations of MHS. These include iterated integrals of (holomorphic) modular forms, but there are many more. Below is an example of such a holomorphic iterated integral that is not of the type considered by Manin. It is, in some sense, a generalization of the Riemann theta function. (Cf. [18, Ex. 4.4].)

**Example 13.4.** Suppose that $f \in M^0_{2n+2}$ and $g \in M^0_{2n+2}$ are modular forms, but there are many more. Below is an example of such a period of admissible variations of MHS. These include iterated integrals of (holomorphic) modular forms, but there are many more. Below is an example of such a period of admissible variations of MHS. These include iterated integrals of (holomorphic) modular forms, but there are many more. Below is an example of such a period of admissible variations of MHS. These include iterated integrals of (holomorphic) modular forms, but there are many more.

Then $\tau \mapsto \int_{\tau_0}^{\tau} \varphi_f(e_g^0) \omega_g(e_g^0) + \xi$ is a well defined function from $\mathfrak{h}$ to $S^n H_\sigma \otimes S^n H_\sigma$. An elementary argument (cf. [18, Prop. 4.3]) implies that it is holomorphic.

Perhaps the most interesting version of this example is where $f = g$ and one composes it with an invariant bilinear form $S^n H_\sigma \otimes S^n H_\sigma \to \mathbb{C}$. Such iterated integrals occur as periods of biextensions.

13.2. **Iterated Shimura integrals.** In [32, 33] Manin considered iterated integrals of (holomorphic) iterated integrals and non-abelian generalizations of modular symbols. Here we briefly discuss the relationship of his work to the Hodge theory of modular groups.

Manin considers iterated integrals with values in the algebras

$$A = \mathbb{C}\langle \langle e_f, e_{2n+2} : f \in \mathfrak{B}_{2n+2}, n \geq 1 \rangle \rangle$$

and

$$B = \mathbb{C}\langle \langle e_{2n+2} : n \geq 1 \rangle \rangle.$$

These iterated integrals are of the form

$$1 + \int_{\tau_0}^{\tau} \Omega + \int_{\tau_0}^{\tau} \Omega \Omega + \int_{\tau_0}^{\tau} \Omega \Omega \Omega + \cdots$$

where

$$\Omega = \Omega_A := \sum_{n \geq 2} \left( \psi_{2n}(e_{2n}) + \sum_{f \in \mathfrak{B}_{2n}} \omega_f(e_f) \right)$$

in the first case and

$$\Omega = \Omega_B := \sum_{n \geq 2} \psi_{2n}(e_{2n})$$

in the second case. Both of these forms are $\Gamma$-invariant.

Let $u_A$ (resp. $u_B$) be the set of primitive elements of $A$ (resp. $u_B$). Then $\Omega_A$ (resp. $\Omega_B$) takes values in $u_A$ (resp. $u_B$). Set

$$u = L(e_0^0 \cdot e_{2n}, e_0^0 \cdot e_f^0, e_0^0 \cdot e_f^0 : n \geq 2, f \in \mathfrak{B}_{2n})^\wedge.$$

It follows from Figure 5 that $F^0 u$ is generated by $\{e_0^0 \cdot e_f^0 : f \in \mathfrak{B}_{2n}, n \geq 2\}$, so that $u_A$ is the quotient of $u$ by the ideal $F^0 u$, and $u_B$ is the quotient of $u$ by the ideal generated by all $e_0^0 \cdot e_f^0$ and $e_0 \cdot e_f$. His iterated integral is the
reduction of the one in the previous section (the first argument of $\tilde{F}$) mod these ideals. This implies that there are many interesting holomorphic iterated integrals that do not occur as iterated Shimura integrals.

One can ask whether the $\text{SL}_2(\mathbb{Z})$ connection on the local system

$$u_B \times \mathfrak{h} \to \mathfrak{h}$$

defined by $\Omega_B$ descends to an admissible VMHS over $M_{1,1}$. It will follow from Theorem 19.4 that it does not as we explain in Remark 19.5.

13.3. Extensions of variations of MHS associated to Eisenstein series. Here we suppose, for simplicity, that $\Gamma = \text{SL}_2(\mathbb{Z})$. In this section, we sketch an explicit construction of an extension

$$0 \to S^{2n}\mathbb{H}(2n+1) \to E \to \mathbb{Q} \to 0$$

for each Eisenstein series $G_{2n}$.

Let $H = \mathbb{C}a \oplus \mathbb{C}w$. Define the Hodge filtration on $H$ by $F^0H = H$ and $F^1H = \mathbb{C}w$. This induces a Hodge filtration on $S^{2n}H$. Trivialize the bundle $H \rightarrow \mathfrak{h}$ with the sections $a$ and $w$:

$$H \cong H \times \mathfrak{h}.$$ 

Trivialize $S^{2n}H$ using monomials in $a$ and $w$. Then $F^pS^{2n}H$ is trivialized by the sections $\{a^{2n-j}w^j : j \geq p\}$.

Set $V = \mathbb{C}e \oplus S^{2n}H(2n+1)$ and $V_h = V \times \mathfrak{h}$. Define Hodge and weight filtrations on $V$ by giving $e$ type $(0,0)$ and $a^{2n-j}w^j$ type $(j-2n-1,-j-1)$. Let $\text{SL}_2(\mathbb{Z})$ act in this bundle by acting trivially on $e$, and on $a$ and $w$ by the factor of automorphy given in Corollary 9.4. The Hodge and weight filtrations are invariant under this action, so that they descend to Hodge and weight filtrations on the (orbifold) quotient bundle

$$V := \text{SL}_2(\mathbb{Z})\backslash V_h \to M_{1,1}.$$ 

This bundle is trivial over the punctured $q$-disk $\Delta^*$. Extend it to a bundle $\overline{V}$ over $\overline{M}_{1,1}$ by defining its sections over the $q$-disk $\Delta$ to be $V \otimes O_{\Delta}$. The Hodge and weight bundles clearly extend to sub-bundles of $\overline{V}$.

Define a connection on $\mathcal{V}_h$ by $d + \Omega$, where

$$\Omega = \begin{pmatrix} \psi_{2n+2}(w^{2n}) & 0 \\ \frac{\partial}{\partial w} & \frac{\partial}{\partial q} \end{pmatrix} \in \mathbb{C} \begin{pmatrix} S^{2n}H & 0 \\ \text{End} S^{2n}H & \text{End} S^{2n}H \end{pmatrix} \frac{dq}{q}.$$ 

It is holomorphic, flat and $\Gamma$-invariant. It therefore descends to a flat connection $\nabla$ on $\mathcal{V}$ which has a regular singular point at the cusp when viewed as a connection on $\overline{\mathcal{V}}$. This implies that the extended bundle is Deligne’s canonical extension of $(\mathcal{V}, \nabla)$ to $\overline{M}_{1,1}$. Since

$$\Omega \in (F^{-1}W_{-1} \text{End } V) \otimes O(\Delta) \frac{dq}{q},$$

the weight filtration is flat and the connection satisfies Griffiths transversality. Since $\psi_{2n+2}(w^{2n})$ has rational periods, it follows that the local system $\mathcal{V}$ associated to $(\mathcal{V}, \nabla)$ has a natural $\mathbb{Q}$-form. The associated weight graded local system is

$$\text{Gr}^W \mathcal{V} = \mathbb{Q}(0) \oplus S^{2n}\mathbb{H}(2n+1).$$

15This construction works equally well when $\Gamma$ is a congruence subgroup. The construction in the more general case is sketched at the end of the next section.
The existence of a relative weight filtration at \( q = 0 \) follows from the argument in the proof of Theorem 7.16. It follows that \( V \) is an admissible variation of MHS over \( \mathcal{M}_{1,1} \). The results of Section 18.4 imply that every extension of \( \mathbb{Q} \) by \( S^{2n} \mathbb{H}(m) \) over \( \mathcal{M}_{1,1} \) is a multiple of this extension when \( m = 2n + 1 \) and trivial otherwise.

### 13.4. Extensions of variations of MHS associated to cusp forms

The construction of the extension corresponding to an eigen cusp form is similar, but a little more elaborate. Suppose that \( \Gamma \) is a congruence subgroup of \( \text{SL}_2(\mathbb{Z}) \). The construction of the extension corresponding to an eigen cusp form is similar, but a little more elaborate. Suppose that \( \Gamma \) is a congruence subgroup of \( \text{SL}_2(\mathbb{Z}) \) and that \( m \geq 0 \). The first step is to construct an extension

\[
0 \to H^1(X_{\Gamma}, S^m \mathbb{H}_\mathbb{Z})^* \otimes S^m \mathbb{H}_\mathbb{Z} \to V \to \mathbb{Z} \to 0
\]

in the category of \( \mathbb{Z} \)-MHS over \( X_\Gamma \).

Denote the completion of \( X_\Gamma \) by \( \overline{X}_\Gamma \). Let \( \nabla \) be the \( C^\infty \) vector bundle over \( \overline{X}_\Gamma \) associated to the canonical extension

\[
\mathcal{O}_{\overline{X}_\Gamma} \oplus H^1(X_{\Gamma}, S^m \mathbb{H})^* \otimes S^m \mathbb{H}
\]

of the admissible variation \( \mathbb{Q} \oplus H^1(X_{\Gamma}, S^m \mathbb{H})^* \otimes S^m \mathbb{H} \) over \( X_\Gamma \). This has natural Hodge and weight sub-bundles. Denote the restriction of \( \nabla \) to \( X_\Gamma \) by \( \nabla \) and the direct sum connection on it by \( \nabla_0 \).

Define a \( C^\infty \) connection on \( \nabla \) by \( \nabla = \nabla_0 + \Omega_{1,m} \), where \( \Omega_{1,m} \) is the form defined in Equation (12.4). This connection is flat, and thus defines a new holomorphic structure on the bundle \( \nabla \). Arguments almost identical to those in Section 7.4 show that \( (\overline{\nabla}, \nabla) \) is Deligne’s canonical extension of \( (\nabla, \nabla) \), that the Hodge bundles are holomorphic sub-bundles of \( \nabla \) with respect to this new complex structure, and that the connection \( \nabla \) satisfies Griffiths transversality. The existence of a relative weight filtration at each cusp is established as in the proof of Theorem 7.16. The fact that \( \Omega_{1,m} \) represents the identity \( H^1(X_{\Gamma}, S^m \mathbb{H}) \to H^1(X_{\Gamma}, S^m \mathbb{H}) \) implies that the local system \( V \) underlying the flat bundle \( (\nabla, \nabla) \) has a natural \( \mathbb{Z} \)-form. It follows that there is an admissible \( \mathbb{Z} \)-VMHS \( \nabla \) over \( X_\Gamma \) whose corresponding \( C^\infty \) vector bundle is \( \nabla \) and whose weight graded quotients are \( \mathbb{Q}(0) \) and \( H^1(X_{\Gamma}, S^m \mathbb{H}_\mathbb{Z})^* \otimes S^m \mathbb{H} \). (Cf. Lemma 7.8.)

Having constructed the extension (13.6), we can now construct the extension corresponding to a Hecke eigen cusp form \( f \in \mathfrak{B}_{m+2}(\Gamma) \). The smallest sub \( \mathbb{Q} \)-HS \( M_f \) of \( H^1(X_{\Gamma}, S^m \mathbb{H}_\mathbb{Q}) \) whose complexification contains \( \omega_f(\mathfrak{e}) \) is pure of weight \( m + 1 \). So \( M_f \otimes S^m \mathbb{H} \) is pure of weight \(-1\). The corresponding extension

\[
0 \to M_f \otimes S^m \mathbb{H}_\mathbb{Z} \to E_f \to \mathbb{Q} \to 0
\]

is obtained by pushing out the extension (13.6) along the dual of the inclusion

\[
M_f \hookrightarrow H^1(X_{\Gamma}, S^m \mathbb{H}_\mathbb{Z}).
\]

This extension has a natural \( \mathbb{Z} \)-form, which we denote by \( E_{f,\mathbb{Z}} \).

The extension \( E_{f,\mathbb{Z}} \) corresponds to a holomorphic section of the associated bundle of intermediate Jacobians, which has fiber

\[
J(H^1(X_{\Gamma}, S^m \mathbb{H})^* \otimes S^m H_x)
\]

over \( x \in X_\Gamma \), where for a \( \mathbb{Z} \)-MHS \( V \) with negative weights

\[
J(V) := V_C/(V_Z + F^0 V_C) \cong \text{Ext}^1_{\text{MHS}}(\mathbb{Z}, V).
\]

The section is obtained by integrating the invariant 1-form \( \omega_f(\mathfrak{e}_f') + \omega_f(\mathfrak{e}_f)' \). More sections can be obtained by applying elements of \( \text{Aut} M_{f,\mathbb{Z}} \).
A similar construction can be used to construct the extension of a normalized Eisenstein series $f$. When $\Gamma = \text{SL}_2(\mathbb{Z})$ this reduces to the construction in the previous section. In this case, the smallest $\mathbb{Q}$-Hodge substructure $M_f$ of $H^1(\overline{X_\Gamma}, S^m \mathbb{H})$ that contains $\psi_f(e)$ is $M_f = \mathbb{Q}(-m - 1)$. Pushing out the extension (13.6) along the inclusion $M_f \to H^1(\overline{X_\Gamma}, S^m \mathbb{H})$ gives the extension

$$0 \to S^m \mathbb{H}(m + 1) \to E_f \to \mathbb{Q} \to 0.$$ 

corresponding to $f$.

14. The Relative Completion of $\pi_1(M_{1,\bar{1}}, x)$

By a slight of hand, can deduce the MHS on the unipotent radical of the relative completion of the fundamental group of $M_{1,\bar{1}}$ from the MHS on the unipotent radical of the relative completion of $\text{SL}_2(\mathbb{Z})$. The MHS on this completion is of interest as it acts on the unipotent completion of the fundamental group of a once punctured elliptic curve.

First recall some classical facts. (Detailed proofs can be found, for example, in [20].) The moduli space $M_{1,\bar{1}}$ of elliptic curves with a non-zero tangent vector at the identity is the complement of the discriminant locus $u^3 - 27v^2 = 0$ in $\mathbb{C}^2$. For us, it is more useful to write it as the quotient of $\mathbb{C}^\ast \times \mathfrak{h}$ by the action

$$\gamma : (\xi, \tau) \mapsto ((c\tau + d)^{-1}\xi, \gamma \tau),$$

where $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. This action is fixed point free, so that $M_{1,\bar{1}}$ is an analytic variety. The projection $\mathbb{C} \times \mathfrak{h} \to \mathfrak{h}$ induces a projection $\pi : M_{1,\bar{1}} \to M_{1,1}$ that is the $\mathbb{C}^\ast$ bundle associated to the orbifold line bundle $L \to M_{1,1}$ with factor of automorphy $c\tau + d$. Modular forms of $\text{SL}_2(\mathbb{Z})$ of weight $m$ are sections of $L^\otimes m$. (Cf. [20, §4].) The cusp form $\Delta$ of $\text{SL}_2(\mathbb{Z})$ of weight 12 trivializes $L^\otimes 12$.

The $\text{SL}_2(\mathbb{Z})$ action lifts to an action of a central extension

$$0 \to \mathbb{Z} \to \hat{\Gamma} \to \text{SL}_2(\mathbb{Z}) \to 1$$

on $\mathbb{C} \times \mathfrak{h}$. The group $\hat{\Gamma}$ is the mapping class group of a genus 1 surface with one boundary component. This extension corresponds to the orbifold $\mathbb{C}^\ast$-bundle $M_{1,\bar{1}} \to M_{1,1}$.

Denote the completion of $\hat{\Gamma}$ with respect to the homomorphism

$$\hat{\Gamma} \to \text{SL}_2(\mathbb{Z}) \hookrightarrow \text{SL}_2(\mathbb{Q})$$

by $\widehat{\mathcal{G}}$ and its prounipotent radical by $\hat{\mathcal{U}}$. Denote the completion of $\text{SL}_2(\mathbb{Z})$ with respect to its inclusion into $\text{SL}_2(\mathbb{Q})$ by $\mathcal{G}$ and its prounipotent radical by $\mathcal{U}$. Denote the Lie algebras of $\mathcal{U}$ and $\hat{\mathcal{U}}$ by $\mathfrak{u}$ and $\hat{\mathfrak{u}}$, respectively. The projection $\hat{\Gamma} \to \text{SL}_2(\mathbb{Z})$ induces a homomorphism $\widehat{\mathcal{G}} \to \mathcal{G}$ that commutes with the projections to $\text{SL}_2$.

**Proposition 14.2.** For each choice of a base point $x \in M_{1,1}$ and each lift $\hat{x}$ of $x$ to $M_{1,\bar{1}}$, there is a natural isomorphism

$$\hat{\mathcal{G}}_x \cong \mathcal{G}_x \times \mathbb{G}_a(1),$$

\[\text{Cf. [20, §8].}\]
where $G_a(1)$ denotes the copy of $G_a$ with the MHS $\mathbb{Q}(1)$. This induces an isomorphism of MHS

$$\hat{g} \cong g \oplus \mathbb{Q}(1).$$

where $\hat{g}$ is given the natural MHS constructed in [16].

**Proof.** Since the weight 12 cusp form $\Delta$ trivializes $L \otimes 12$ and since $M_{1,1}$ is $L^*$, there is a 12-fold covering

$$M_{1,1} \to M_{1,1} \times \mathbb{C}^*$$

that commutes with the projections to $M_{1,1}$. It induces an inclusion

$$0 \to \mathbb{Z} \to \hat{\Gamma} \to \text{SL}_2(\mathbb{Z}) \to 1$$

of extensions. The completion of $\text{SL}_2(\mathbb{Z}) \times \mathbb{Z}$ with respect to the obvious homomorphism to $\text{SL}_2(\mathbb{Q})$ is $\hat{G} \times G_a$. This and the right exactness (Prop. 3.6) of relative completion imply that the commutative diagram

$$\begin{array}{cccccc}
0 & \to & \mathbb{Z} & \to & \hat{\Gamma} & \to & \text{SL}_2(\mathbb{Z}) & \to & 1 \\
\times & & \downarrow & & \phi & & \downarrow & & \\
0 & \to & \mathbb{Z} & \to & \text{SL}_2(\mathbb{Z}) \times \mathbb{Z} & \to & \text{SL}_2(\mathbb{Z}) & \to & 1 \\
\end{array}$$

has exact rows. It follows that $\phi_\ast : \hat{G} \to G \times G_a$ is an isomorphism. The Hodge theoretic statements follow from the functoriality of the MHS on relative completion. □

There is therefore an isomorphism $\hat{u} \cong u \oplus \mathbb{C}e_2$, in the category of pronilpotent Lie algebras with an $\text{SL}_2$ action. The new generator $e_2$ spans a copy of the trivial representation of $\text{SL}_2$ and commutes with the remaining generators

$$\bigcup_{n>0} \{e_0^j \cdot e_f, e_0^j \cdot e_f', e_0^j \cdot e_{2n} : 0 \leq j \leq 2n - 2, f \in \mathfrak{h}_{2n}\}.$$

The Hodge type of $e_2$ is $(-1, -1)$, which is consistent with the Hodge types of the other $e_{2m+2,p}$ given in Figure 4.

**Remark 14.3.** One can lift the power series connection $\Omega$ whose monodromy representation $\text{SL}_2(\mathbb{Z}) \to \text{SL}_2 \times \hat{U}$ is the relative completion of $\text{SL}_2(\mathbb{Z})$ to a power series connection $\hat{\Omega}$ whose monodromy homomorphism $\hat{\Gamma} \to \text{SL}_2 \times \hat{U}$ is the relative completion of $\hat{\Gamma}$.

The normalized Eisenstein series $G_2(\tau)$ is also defined by the series (12.6), suitably summed. Although $G_2$ is not a modular form, it satisfies (cf. [41, pp. 95-96])

$$G_2(\gamma \tau) = (c\tau + d)^2 G_2(\tau) + ic(c\tau + d)/4\pi.$$

This implies that

$$\psi_2 := G_2(\tau) d\tau - \frac{1}{4\pi i} \frac{d\xi}{\xi} \in E^1(\mathbb{C}^* \times h)$$
is $\text{SL}_2(\mathbb{Z})$-invariant, and thus a closed 1-form on $\mathcal{M}_{1,1}$.\footnote{It is useful to note that $\psi_2 = -\frac{1}{24(2\pi i)^2} \frac{dD}{D}$, where, where $D = u^3 - 27v^2$ denotes the discriminant function on $\mathcal{M}_{1,1}$. This is because there is a unique logarithmic 1-form on $\mathcal{M}_{1,1}$ with given residue along the divisor of nodal cubics. Cf. [21, Eqn. 19.1], where $D$ is denoted $\Delta$.}

If $\Omega \in K^1(\mathcal{M}_{1,1}, \mathcal{P}; \mathfrak{u})$ is a power series connection (as constructed above), then

$$\hat{\Omega} = \Omega + \psi_2 \mathbf{e}_2.$$ 

is an integrable $\text{SL}_2(\mathbb{Z})$-invariant power series connection with values in $\hat{\mathbf{u}} := \mathbf{u} \oplus \mathbb{C}\mathbf{e}_2$.

For each choice of a lift $\hat{x} \in \mathbb{C} \times \mathfrak{h}$ of a base point $x \in \mathcal{M}_{1,1}$, the monodromy representation

$$\hat{\Gamma} \to \text{SL}_2(\mathbb{C}) \ltimes \hat{\mathbf{u}}$$

induces isomorphisms $\hat{G}_x \cong \text{SL}_2 \times \hat{\mathbf{u}} \cong (\text{SL}_2 \ltimes \mathcal{U}) \times \mathbb{G}_a$.

15. The Monodromy Representation

Let $E$ be an elliptic curve with identity 0. Set $E' = E = \{0\}$ and let $\vec{v} \in T_0E$ be a non-zero tangent vector. Denote the Lie algebra of the unipotent completion of $\pi_1(E', \vec{v})$ by $\mathfrak{p}(E, \vec{v})$. Recall from Section 3.4.3 that this is a completed free Lie algebra with abelianization $H_1(E)$.

Denote by $\mathfrak{p}$ the local system over $\mathcal{M}_{1,1}$ whose fiber over $[E, \vec{v}]$ by $\mathfrak{p}(E, \vec{v})$. Fix a base point $x_0 = [E_0, \vec{v}_0]$ of $\mathcal{M}_{1,1}$. Set $H_o = H_1(E_0)$ and $\mathfrak{p}_o = \mathfrak{p}(E_0, \vec{v}_0)$. Denote the completion of $\pi_1(\mathcal{M}_{1,1}, x_0)$ relative to the standard homomorphism to $\text{SL}(H_o)$ by $\hat{G}_o$ and its pronnipotent radical by $\hat{U}_o$. Denote their Lie algebras by $\hat{\mathfrak{g}}_o$ and $\hat{\mathfrak{u}}_o$, respectively.

The monodromy action $\pi_1(\mathcal{M}_{1,1}, x_0) \to \text{Aut} \mathfrak{p}_o$ respects the lower central series of $\mathfrak{p}_o$ and acts on each graded quotient through an action of $\text{SL}(H_o)$. The universal mapping property of relative completion implies that the monodromy representation above induces a homomorphism

$$\hat{G}_o \to \text{Aut} \mathfrak{p}_o.$$ 

This induces a homomorphism $\hat{\mathfrak{g}}_o \to \text{Der} \mathfrak{p}_o$ that we shall call the infinitesimal monodromy representation.

**Proposition 15.1.** The infinitesimal monodromy action $\hat{\mathfrak{g}}_o \to \text{Der} \mathfrak{p}_o$ is a morphism of MHS.

**Sketch of Proof.** The universal punctured elliptic curve $E' \to \mathcal{M}_{1,1}$ has fiber $E'$ over $[E, \vec{v}] \in \mathcal{M}_{1,1}$. The tangent vector $\vec{v}_o$ of $E$ at 0 can be regarded as a tangential base point of $E'$. The diagram

$$
\begin{array}{cccccc}
1 & \to & \pi_1(E_0, \vec{v}_0) & \to & \pi_1(E', \vec{v}_0) & \to & \pi_1(\mathcal{M}_{1,1}, x_0) & \to & 1 \\
| & & | & & | & & | & & |
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
1 & \to & \text{SL}(H_o) & \to & \text{SL}(H_o) & \to & 1
\end{array}
$$

gives rise to an exact sequence

$$1 \to \mathcal{P}_o \to \mathcal{G}_{E,o} \to \hat{\mathfrak{g}}_o \to 1.$$ 

of completions that is compatible with mixed Hodge structures. Here $\mathcal{G}_{E,o}$ denotes the completion of $\pi_1(E', \vec{v}_0)$ with respect to the natural homomorphism to $\text{SL}(H_o)$.
and $P_o$, the unipotent completion of $\pi_1(E'_o, \bar{v_o})$. One has exactness on the left as $P_o$ has trivial center. The conjugation action of $G_{E,o}$ on $P_o$ induces a homomorphism $g_{E,o} \to \text{Der} p_o$ that his a morphism of MHS.

The tangent vectors $\bar{v}$ induce a section of $\pi_1(E'_o, \bar{v_o}) \to \pi_1(M_{1,\Gamma}, x_o)$. It induces a section of $G_{E,o} \to G_{E,o}$ that is compatible with mixed Hodge structures. The natural action of $G_{E,o}$ on $P_o$ is the composite $G_{E,o} \to g_{E,o} \to \text{Der} p_o$ and is therefore a morphism of MHS. □

Since $L^m p_o = W_{-m} p_o$, there is a canonical isomorphism (cf. (2.3))

$$\text{Gr}_W^W p_o \cong L(H_o).$$

of graded Lie algebras in the category of $\text{SL}(H_o)$ modules. The map on each graded quotient is an isomorphism of mixed Hodge structures.

The element $\sigma$ of $\pi_1(E'_o, \bar{v_o})$ obtained by rotating the tangent vector once around the identity is trivial in homology and thus lives in the commutator subgroup. The image of its logarithm in

$$\text{Gr}_W^W p_o \cong \Lambda^2 H_o$$

is $[a, b]$, where $a, b$ is any symplectic basis of $H_1(E)$. It spans a copy of the trivial representation. Let

$$\text{Der}^0 L(H_o) = \{ \delta \in \text{Der} L(H_o) : \delta([a, b]) = 0 \}.$$

Since the natural action of $\pi_1(M_{1,\Gamma}, x_o)$ on $\pi_1(E'_o, \bar{v_o})$ fixes $\sigma$, we have:

**Corollary 15.2.** The image of the infinitesimal monodromy representation

(15.3) $$\text{Gr}_W^W \hat{u}_o \to \text{Der} L(H_o)$$

lies in $\text{Der}^0 L(H_o)$. □

The Lie algebra $\text{Gr}_W^W \hat{u}_o$ is freely generated by the image of any $\text{SL}(H_o)$-invariant Hodge section of $\text{Gr}_W^W \hat{u}_o \to \text{Gr}_W^W \hat{u}_o$. Since this projection is an isomorphism in weight $-1$, each cuspidal generator $e'_f$ and $e''_f$ has a canonical lift to $\text{Gr}_W^W \hat{u}_o$. Fix a lift $\hat{e}_2n$ of each Eisenstein generator $e_{2n}$.

**Theorem 15.4.** The image of the graded monodromy representation (15.3) is generated as an $\text{SL}(H_o)$-module by the images of the $\hat{e}_{2n}$, $n \geq 1$.

**Proof.** First observe that $\text{Gr}_W^W \text{Der}^0 L(H_o) = 0$. This is because

$$\text{Gr}_W^W L(H_o) = H_o$$

and $\text{Gr}_W^W L(H_o) = \mathbb{Q}[a, b]$. $\text{Gr}_W^W L(H_o) \cong H_o$. The element $u \in H_o$ corresponds to the derivation $\text{ad}_u$. Since $\text{ad}_u([a, b]) = [u, [a, b]] \neq 0$ for all non-zero $u \in H_o$, $\text{Gr}_W^W \text{Der}^0 L(H) = 0$.

Since each $e'_f$ and $e''_f$ in $\text{Gr}_W^W \hat{u}_o$ has weight $-1$, this vanishing implies that $e_{2n}' \cdot e_{2n}''$ are in the kernel of the graded monodromy representation. It follows that the image is generated by the images of the remaining generators — the Eisenstein generators $e_{2n}' \cdot \hat{e}_{2n}$.

The next task is to identify the images of the $\hat{e}_{2n}$ in $\text{Der}^0 L(H_o)$. For each $n \geq 0$ a basis $v_1, v_2$ of $H$ define derivations $\varepsilon_{2n}(v_1, v_2)$ by

(15.5) $$
\varepsilon_{2n}(v_1, v_2) := \begin{cases} -v_2 \frac{\partial}{\partial v_1} & m = 0; \\ \text{ad}_{v_1}^{2n-1}(v_2) - \sum_{j+k=2n-1}(-1)^j[\text{ad}_{v_1}^j(v_2), \text{ad}_{v_1}^k(v_2)]\frac{\partial}{\partial v_2} & m > 0. \end{cases}
$$
Here we are identifying $L(H)$ with its image in $\text{Der} L(H)$.

The following result implies that the image of $\mathfrak{e}_{2n}$ in $\text{Der}^0 L(H)$ depends only on $\mathfrak{e}_{2n}$ and not on the choice of the lift $\tilde{\mathfrak{e}}_{2n}$.

**Proposition 15.6** (Hain-Matsumoto). For each $n \geq 1$ there is a unique copy of $S^{2n} H(2n + 1)$ in $\text{Gr}^W_{2n - 2} \text{Der}^0 L(H)$. It has highest weight vector the derivation $\epsilon_{2n}(v_1, v_2)$, where $v_1, v_2 \in H$ are non-zero vectors of $\mathfrak{s}\mathfrak{l}_2$-weight 1 and $-1$, respectively. 

It follows that the image of $\tilde{\mathfrak{e}}_{2n}$ in $\text{Der} L(H_n)$ is a multiple (possibly zero) of $\epsilon_{2n}(\mathfrak{b}, \mathfrak{a})$. We compute this multiple using the universal elliptic KZB-connection [6, 31, 21], which provides an explicit formula for the connection on the bundle $p$ over $\mathcal{M}_{1,1}$.

**Theorem 15.7.** For all $n \geq 0$, and all choices of the lift $\tilde{\mathfrak{e}}_{2n}$, the image of $\tilde{\mathfrak{e}}_{2n}$ under the graded monodromy representation (15.3) is $2\epsilon_{2n}(\mathfrak{b}, \mathfrak{a})/(2n - 2)!$

**Proof.** Trivialize the pullback of $\mathcal{H}$ to $\mathbb{C}^* \times \mathfrak{h}$ by the sections

$$T := \tau \mathfrak{a} - \mathfrak{b} = \exp(\tau \mathfrak{e}_0)(-\mathfrak{b}) \text{ and } A := (2\pi i)^{-1} \mathfrak{a}.$$ 

In [21, §13–14] it is shown that the pullback of $\mathfrak{p}$ to $\mathbb{C}^* \times \mathfrak{h}$ may be identified with the trivial bundle

$$L(T, A)^\wedge \times \mathbb{C}^* \times \mathfrak{h} \to \mathbb{C}^* \times \mathfrak{h}$$

with the connection $\nabla = d + \omega'$, where

$$\omega' = -2\pi i \left(d\tau \otimes \epsilon_0(T, A) + \sum_{m \geq 1} \frac{2}{(2n - 2)!} G_{2n}(\tau) d\tau \otimes \epsilon_{2n}(T, A)\right).$$

To prove the result, we need to rewrite this in terms of the frame $-\mathfrak{b}, \mathfrak{a}$ of $\mathcal{H}$. First note that $\epsilon_{2n}(v_1, v_2, c_1 v_1, c_2 v_2) = c_1^{2n-1} c_2 \epsilon_{2n}(v_1, v_2)$ and that if $g \in \text{SL}(H)$, then $\epsilon_{2n}(g v_1, g v_2) = g \cdot \epsilon_{2n}(v_1, v_2)$, where $g \in \text{SL}(H)$ acts on a derivation $\delta$ by $g \cdot \delta := g \delta g^{-1}$. Since $\mathfrak{e}_0 \cdot \mathfrak{a} = 0$, these imply that

$$2\pi i \epsilon_{2n}(T, A) = \epsilon_{2n}(T, \mathfrak{a}) = \exp(\tau \mathfrak{e}_0)(-\mathfrak{b}), \exp(\tau \mathfrak{e}_0)\mathfrak{a} = -\exp(\tau \mathfrak{e}_0) \cdot \epsilon(\mathfrak{b}, \mathfrak{a}).$$

It follows that $2\pi i G_{2n}(\tau) d\tau \otimes \epsilon_{2n}(T, A) = -\psi_{2n}(\epsilon_{2n}(\mathfrak{b}, \mathfrak{a}))$.

Since the natural connection $\nabla_0$ on $\mathcal{H}$ is given by

$$\nabla_0 = d - 2\pi i \epsilon_0(T, A) \otimes d\tau,$$

the pullback connection may be written

$$\nabla = \nabla_0 - 2\pi i \sum_{m \geq 1} \frac{2}{(2n - 2)!} G_{2n}(\tau) d\tau \otimes \epsilon_{2n}(T, A)$$

$$= \nabla_0 + \sum_{m \geq 1} \frac{2}{(2n - 2)!} \psi_{2n}(\epsilon_{2m}(\mathfrak{b}, \mathfrak{a})).$$

It follows that regardless of the choice of the lifts of $\mathfrak{e}_{2n}$, the generator $\tilde{\mathfrak{e}}_{2n}$ goes to $2\epsilon_{2n}(\mathfrak{b}, \mathfrak{a})/(2n - 2)!$ under the graded monodromy representation. 

**Remark 15.8.** Since $\mathfrak{g} = \mathfrak{g} \oplus \mathbb{Q}(1)$, there are natural representations

$$\mathfrak{g} \to \text{Der} \mathfrak{p} \text{ and } \text{Gr}^W \mathfrak{g} \to \text{Der}^0 L(H).$$

There are also the outer actions

$$\mathfrak{g} \to \text{OutDer} \mathfrak{p} \text{ and } \text{Gr}^W \mathfrak{g} \to \text{OutDer} L(H).$$
The representations $\operatorname{Gr}^W_x g \to \operatorname{Der} \mathbb{L}(H)$ and $\operatorname{Gr}^W_x g \to \operatorname{OutDer} \mathbb{L}(H)$ have the same kernel as $e_2 \notin g$ and as

$$\operatorname{InnDer} \mathbb{L}(H) \cap \operatorname{Der}^0 \mathbb{L}(H) = \mathbb{Q} e_2 (b, a).$$

Exactness of $\operatorname{Gr}^W_x$ implies that $g \to \operatorname{Der} p$ and $g \to \operatorname{OutDer} p$ have the same kernel. Since it is generally easier to work with derivations than with outer derivations, we will work with $g \to \operatorname{Der} p$.

16. The Eisenstein Quotient of a Completed Modular Group

The results of the previous section imply that for all $x \in M_{1,1}$, each weight graded quotient of the image of $g_x$ in $\operatorname{Der} p_x$ is a sum of Tate twists $S^m H_x(r)$ of symmetric powers of $H_x$. Any such Lie algebra quotient of $g_x$ has the property that its weight associated graded is generated by the images of the Eisenstein generators $e_2$.

Suppose that $\Gamma$ is a finite index subgroup of $\text{SL}_2(\mathbb{Z})$. Denote the the completion of $\pi_1(X_\Gamma, x)$ with respect to the inclusion $\Gamma \to \text{SL}_2(H_x)$ by $G_x$ and its pronilpotent radical by $U_x$. Denote their Lie algebras by $g_x$ and $u_x$, respectively.

**Proposition 16.1.** For each $x \in X_\Gamma$ there is a unique maximal quotient $g_x^{\text{eis}}$ of $g_x$ in the category of Lie algebras with a mixed Hodge structure with the property that each weight graded quotient of $g_x^{\text{eis}}$ is a sum of Tate twists of symmetric powers of $H_x$. Moreover, the Lie algebra isomorphism $g_x \to g_y$ corresponding to a path from $x$ to $y$ in $X_\Gamma$ induces a Lie algebra (but not a Hodge) isomorphism $g_x^{\text{eis}} \to g_y^{\text{eis}}$. The corresponding local system $g^{\text{eis}} := (g_x^{\text{eis}})_{x \in X_\Gamma}$ underlies an admissible VMHS.

The quotient $g_x^{\text{eis}}$ will be called the 

**Eisenstein quotient** of $g_x$. The corresponding quotient of $G_x$ will be denoted by $G_x^{\text{eis}}$.

**Remark 16.2.** Note that if we instead use a tangential base point $\bar{v}$, then $H_{\bar{v}}$ is an extension of $\mathbb{Q}$ by $\mathbb{Q}(1)$, so that $g_{\bar{v}}^{\text{eis}}$ is a mixed Hodge-Tate structure. (That is, all of its $M_*$ weight graded quotients are of type $(p,p)$.) In this case, $g_{\bar{v}}^{\text{eis}}$ is the maximal Tate quotient of $g_{\bar{v}}$.

**Corollary 16.3.** When $\Gamma = \text{SL}_2(\mathbb{Z})$, the monodromy homomorphism $g_x \to \operatorname{Der} p_x$ factors through $g_x^{\text{eis}}$:

$$g_x \longrightarrow g^{\text{eis}}_x \longrightarrow \operatorname{Der} p_x$$

\[ \square \]

Note that if $\Gamma$ has finite index in $\text{SL}_2(\mathbb{Z})$, then the Eisenstein quotient of its relative completion surjects onto the Eisenstein quotient of the relative completion of $\text{SL}_2(\mathbb{Z})$.

**Proof of Proposition 16.1.** If $h_1$ and $h_2$ are quotients of $g_x^{\text{eis}}$ whose weight graded quotients are sums of Tate twists of symmetric powers of $H_x$, then the image $h$ of $g_x^{\text{eis}} \to h_1 \oplus h_2$ is a quotient of $g_x^{\text{eis}}$ whose weight graded quotients are sums of twists of symmetric powers of $H_x$. It also surjects onto $h_1$ and $h_2$. This implies that the “Eisenstein quotients” of $g_x$ form an inverse system from which it follows that the Eisenstein quotient is unique. Note that since $	ext{sl}(H_x) \cong S^2 H_x$, $g_x$ surjects onto $\text{sl}(H_x)$. 

We begin the proof of the second part with an observation. Suppose that $V$ is a MHS and that $K$ is a subspace of $V$ that is defined over $\mathbb{Q}$. Give it the induced weight filtration. Then there is a natural isomorphism
\[ \text{Gr}^W_m(V/K) \cong (\text{Gr}^W_m V)/(\text{Gr}^W_m K). \]
This isomorphism respects the Hodge filtration on each induced from the Hodge filtration $F^\bullet \cap (W_m V)$ of $W_m V$. These are defined as the images of the maps
\[ F^p W_m V \to (W_m V)/(W_m K) \to \text{Gr}^W_m (V/K) \]
and
\[ F^p W_m V \to \text{Gr}^W_m V \to (\text{Gr}^W_m V)/(\text{Gr}^W_m K). \]
The observation is that if this Hodge filtration defines a Hodge structure on each $\text{Gr}^W_m (V/K)$, then $K$ is a sub MHS of $V$ and $V/K$ is a quotient MHS of $V$.

Now apply this with $V = g_y$ and $K$ the ideal of $g_y$ that corresponds to the kernel of $g_x \to g_x^{\text{eis}}$ under the isomorphism $g_x \cong g_y$ given by parallel transport. This implies that $g_y/K$ is a quotient of $g_y$ in the category of MHS whose weight graded quotients are sums of twists of symmetric powers of $H_y$. It is therefore an Eisenstein quotient of $g_y$.

The last statement follows from the fact if $W$ is a quotient of the local system underlying an admissible variation of MHS $V$ with the property that each fiber of $W_x$ has a MHS that is the quotient of the MHS on $V_x$, then $W$ is an admissible variation of MHS. \[ \square \]

**Corollary 16.4.** For all base points (regular, tangential), the category $\text{HRep}(g^{\text{eis}})$ of Hodge representations of $g^{\text{eis}}$ is equivalent to the category of admissible VMHS over $X_\Gamma$ whose weight graded quotients are sums of Tate twists $S^n \mathbb{H}(r)$ of symmetric powers of $\mathbb{H}$. \[ \square \]

We will call such variations over a modular curve *Eisenstein variations of MHS*. Like Tate VMHS in the unipotent case (cf. [28]), Eisenstein variations over a modular curve can be written down reasonably explicitly. This follows from the constructions of Section 8. Suppose that $A$ is an Eisenstein variation over $X_\Gamma$. Set
\[ A_{m,n} = H^0\left( X_\Gamma, \text{Hom}_\mathbb{Q}(S^n \mathbb{H}, \text{Gr}^W_m A) \right) \]
This is a Tate Hodge structure of weight $m - n$. There is a natural isomorphism
\[ \text{Gr}^W_m A \cong \bigoplus_n A_{m,n} \otimes S^n \mathbb{H}. \]
For each $r$ satisfying $0 \leq r \leq \min(n, \ell)$, fix a highest weight vector $h^{(r)}_{n,\ell}$ of $\mathfrak{sl}_2$-weight $n + \ell - 2r$ in $\text{Hom}(S^n H, S^\ell H)$, so that
\[ \text{Hom}(S^n \mathbb{H}, S^\ell \mathbb{H}) \cong \bigoplus_{r=0}^{\min(n, \ell)} S^{n+\ell-2r}(h^{(r)}_{n,\ell}). \]
Implicit here is that $h^{(r)}_{n,\ell}$ has Hodge weight $\ell - n$. Set $A = A \otimes \mathcal{O}_{X_\Gamma}$. Denote the natural connection on it by $\nabla$. Set
\[ A_m = \left( \text{Gr}^W_m A \right) \otimes \mathcal{O}_{X_\Gamma} \cong \bigoplus_n A_{m,n} \otimes S^n \mathbb{H}. \]
The standard connection on $\mathcal{H}$ induces a connection on each of these that we denote by $\nabla_0$. The construction of Section 8 imply that for each cusp $P \in D$ of $X_\Gamma$, there are linear maps

$$\varphi_{k,\ell, P}^{m,n} \in F^{\ell-r+1} W_{2\ell-2r+2} \text{Hom}_C(A_{m,n}, A_{k, \ell})$$

such that

$$\langle A, \nabla \rangle \simeq \bigoplus_m A_{m,n} \otimes (S^n \mathcal{H}, \nabla_0 + \Omega)$$

where

$$\Omega = \sum_{P \in D} \sum_{n, \ell \geq 0} \sum_{r=0}^{\min(n, \ell)} \sum_{m,k} \varphi_{k,\ell, P}^{m,n} \otimes \psi_{n+\ell-2r+2, P}(h_r^{(r)}).$$

Implicit in this statement is that the canonical extension $\overline{A}$ of $(A, \nabla)$ is isomorphic to $\bigoplus_{m,n} A_{m,n} \otimes (S^n \mathcal{H}, \nabla_0).$

The isomorphism (16.6) is bifiltered with respect to the Hodge and weight filtrations. The condition (16.5) implies that $\Omega \in F^0 W_{-1} K^1(\overline{X}_\Gamma, D; \text{End}(\text{Gr}^W_{\mathcal{H}}))$.

Caution: not every such 1-form $\Omega$ defines the structure of an admissible variation of MHS over $X_\Gamma$. The issue is that one needs the monodromy of $(A, \nabla_0 + \Omega)$ to be defined over $\mathbb{Q}$. Determining which $\Omega$ give rise to Eisenstein variations is closely related to the problem of determining the relations in $u^{\text{eis}}$.

17. Modular Symbols and Pollack’s Quadratic Relations

Motivic arguments (cf. [24] and Section 20) suggested that $u^{\text{eis}}_x$ may not be freely generated by the $e_{0}^j \cdot e_m$ and predict that the relations that hold between the $e_{0}^j \cdot e_m$ arise from cusp forms. In other words, cusp forms go from being generators of $u_x$ to relations in $u_x^{\text{eis}}$. The goal of the rest of this paper is to sketch a Hodge theoretic explanation for these relations. For this we will need to recall some basic facts about modular symbols, which record the periods of cusp forms and determine the HS on $H^1_{\text{cusp}}(\mathcal{M}_{1,1}, S^{2m} \mathbb{H})$.

17.1. Modular Symbols. Modular symbols are homogeneous polynomials attached to cusp forms of $SL_2(\mathbb{Z})$. They play two roles: they give a concrete representation of the cohomology class associated to a cusp form; secondly, modular symbols of degree $m$ record the periods of the MHS on $H^1(\mathcal{M}_{1,1}, S^m \mathbb{H}) \cong H^1(SL_2(\mathbb{Z}), S^m \mathcal{H})$. A standard reference is [30, Ch. IV].

Recall that $SL_2(\mathbb{Z})$ has presentation

$$SL_2(\mathbb{Z}) = \langle S, U : S^2 = U^3, S^4 = U^6 = I \rangle,$$

where

$$S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \quad U := ST = \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}$$

The action of $SL_2(\mathbb{Z})$ on $\mathfrak{h}$ factors through

$$PSL_2(\mathbb{Z}) := SL_2(\mathbb{Z})/(\pm I) = \langle S, U : S^2 = U^3 = I \rangle.$$
17.1.1. **Group cohomology.** Suppose that $\Gamma$ is a group and that $V$ is a left $\Gamma$-module. Then one has the complex

\[
0 \longrightarrow C^0(\Gamma, V) \xrightarrow{\delta} C^1(\Gamma, V) \xrightarrow{\delta} C^2(\Gamma, V) \xrightarrow{\delta} \cdots
\]

of standard cochains, where $C^i(\Gamma, V) = \{\text{functions } \phi : \Gamma^i \rightarrow V\}$. The differential takes $v \in V = C^0(\Gamma, V)$ to the function $\delta v : \gamma \mapsto (\gamma - 1)v$ and $\delta : C^i(\Gamma, V) \rightarrow C^{i+1}(\Gamma, V)$ takes $\phi : \Gamma \rightarrow V$ to the function

\[
(\delta \phi)(\gamma_1, \gamma_2) \mapsto \phi(\gamma_1) - \phi(\gamma_1 \gamma_2) + \gamma_1 \cdot \phi(\gamma_2).
\]

So $\phi$ is a 1-cocycle if and only if $\phi(\gamma_1 \gamma_2) = \phi(\gamma_1) + \gamma_1 \cdot \phi(\gamma_2)$. The cohomology $H^1(\Gamma, V)$ of $\Gamma$ with coefficients in $V$ is defined to be the homology of this complex.

Now suppose that $V$ is a real or complex vector space and that $\Gamma$ acts on a simply connected manifold $X$. Fix a base point $x_0 \in X$. As in Proposition 4.3, to each $\gamma \in \Gamma$ we can associate the unique homotopy class $c_\gamma$ of paths in $X$ from $x_0$ to $\gamma \cdot x_0$. If $\omega \in E^1(X) \otimes V$ is $\Gamma$ invariant, then the function

\[
\phi : \gamma \mapsto \int_{c_\gamma} \omega
\]

is a 1-cocycle. Changing the base point from $x_0$ to $x'$ changes $\phi$ by the coboundary of $\int_{x_0}^{x'} \omega \in V$. (Cf. Remark 4.4.) This construction induces a map

\[
H^1(E^1(X \times V)^\Gamma) \rightarrow H^1(\Gamma, V),
\]

which is an isomorphism when $\Gamma$ acts properly discontinuously and virtually freely on $X$. This is the case when $\Gamma$ is a modular group and $X$ is the upper half plane.

Suppose that $V$ is divisible as an abelian group. When $-I$ acts trivially on $V$, $V$ is the pullback of a $\text{PSL}_2(\mathbb{Z})$-module and

\[
H^1(\text{PSL}_2(\mathbb{Z}), V) \rightarrow H^1(\text{SL}_2(\mathbb{Z}), V)
\]

is an isomorphism.

17.1.2. **Cuspidal cohomology.** Suppose that $F$ is a field of characteristic zero. Set $H_F = Fa \oplus Fb$. Define $C^*_{\text{cusp}}(\text{SL}_2(\mathbb{Z}), S^{2n}H_F)$ to be the kernel of the restriction mapping

\[
C^* (\text{SL}_2(\mathbb{Z}), S^{2n}H_F) \rightarrow \tilde{C}^* (\langle T \rangle, S^{2n}H_F)
\]

where the right hand complex is the quotient of $C^* (\langle T \rangle, S^{2n}H_F)$ by $a^{2n}$ in degree 0. Set

\[
H^*_{\text{cusp}}(\text{SL}_2(\mathbb{Z}), S^{2n}H_F) := H^*(C^*_{\text{cusp}}(\text{SL}_2(\mathbb{Z}), S^{2n}H_F)).
\]

The corresponding long exact sequence gives the exact sequence

\[
0 \rightarrow H^1_{\text{cusp}}(\text{SL}_2(\mathbb{Z}), S^{2n}H_F) \rightarrow H^1(\text{SL}_2(\mathbb{Z}), S^{2n}H_F)
\]

\[
\rightarrow H^1(\langle T \rangle, S^{2n}H_F) \rightarrow H^2_{\text{cusp}}(\text{SL}_2(\mathbb{Z}), S^{2n}H_F) \rightarrow 0.
\]

This is an instance of the exact sequences (6.3) and (11.3) where $C' = M_{1,1}$.

The cuspidal cohomology group $H^1_{\text{cusp}}(\text{SL}_2(\mathbb{Z}), S^{2n}H_F)$ has a nice description. Recall that $\text{SL}_2(\mathbb{Z})$ acts on $H$ via the formula (10.1) with $v_1 = -b$ and $v_2 = a$. 
Proposition 17.1. Suppose that $F$ is a field of characteristic zero. For all $n \geq 1$, there is an isomorphism

$$H^1_{\text{cusp}}(\SL_2(\mathbb{Z}), S^{2n} H_F)$$

with the set of $r(\mathbf{a}, \mathbf{b}) \in S^{2n} H_F$ that satisfy

$$(I + S)r(\mathbf{a}, \mathbf{b}) = 0 \quad \text{and} \quad (I + U + U^2)r(\mathbf{a}, \mathbf{b}) = 0$$

modulo $\mathbf{a}^{2n} - \mathbf{b}^{2n}$

Proof. Suppose that $\phi : \SL_2(\mathbb{Z}) \to S^{2n} H_F$ is a cuspidal 1-cocycle. Since $-I$ acts trivially on $S^{2n} H$, the cocycle condition and the equation $(-I)^2 = 1$ imply that $\phi(-I) = 0$. Since $S$ and $U$ generate $\SL_2(\mathbb{Z})$, $\phi$ is determined by $\phi(S)$. Since $U = ST$,

$$\phi(U) = \phi(ST) = \phi(S) + S\phi(T) = \phi(S).$$

Thus $\phi$ is determined by $\phi(S)$. Denote this element of $S^{2n} H_F$ by $t_\phi(\mathbf{a}, \mathbf{b})$.

Conversely, if $r(\mathbf{a}, \mathbf{b}) \in S^{2n} H_F$ satisfies these equations, then it determines a cuspidal cocycle by $\phi(S) = \phi(U) = r(\mathbf{a}, \mathbf{b})$.

The last statement follows as the only cuspidal coboundaries are scalar multiplies of $\delta \mathbf{a}^{2n}$. This has value $r(\mathbf{a}, \mathbf{b}) = \mathbf{b}^{2n} - \mathbf{a}^{2n}$ on $S$. \hfill \Box

Remark 17.3. Since $(I + S) \sum j c_j a^j b^{2n-j}$ vanishes if and only if $c_{2n-j} = (-1)^{j+1} c_j$ for all $j$, the terms of a cocycle $r(\mathbf{a}, \mathbf{b})$ of top degree in $\mathbf{a}$ and $\mathbf{b}$ is a multiple of $\mathbf{a}^{2n} - \mathbf{b}^{2n}$. Since this corresponds to the coboundary of $\mathbf{a}^{2n}$, we can identify $H^1_{\text{cusp}}(\SL_2(\mathbb{Z}), S^{2n} H_F)$ with those $r(\mathbf{a}, \mathbf{b})$ that satisfy the cocycle conditions (17.2) and have no terms of degree $2n$ in $\mathbf{a}$ or $\mathbf{b}$.

17.1.3. Modular symbols. If $f$ is a cusp form of weight $2n + 2$, the $S^{2n} H$-valued 1-form $\omega_f(\mathbf{b}^{2n})$ is $\SL_2(\mathbb{Z})$-invariant. Since $f$ is a cusp form, it is holomorphic on the $q$-disk. We can therefore take the base point $x_o$ above to be the cusp $q = 0$. Since $T$ fixes $q = 0$, the function

$$\gamma \mapsto (2\pi i)^{n+1} \int_{x_o}^\gamma \omega_f(\mathbf{b}^{2n}) \in S^{2n} H$$

is a well defined cuspidal 1-cocycle. The modular symbol of $f$ is its value\textsuperscript{18}

$$r_f(\mathbf{a}, \mathbf{b}) := \int_0^1 f(q) w^{2n} dq/q = -(2\pi i)^{2n+1} \int_0^\infty f(iy)(b - iy\mathbf{a})^{2n} d(iy) \in S^{2n} H$$

on $S$. It satisfies the cocycle condition (17.2) and represents the class

$$(2\pi i)^{2n+1} \omega_f(\mathbf{b}^{2n}) \in H^1_{\text{cusp}}(\mathcal{M}_{1,1}, S^{2n} \mathbb{H}).$$

It determines $f$.\textsuperscript{18}

---

\textsuperscript{18}We use this normalization because, if $f \in \mathfrak{M}_{2n+2}$, then $f(q)w^{2n}dq/q \in H^1_{\text{DR}}(\mathcal{M}_{1,1}/Q, S^{2n} H)$. Cf. [21, §21].
17.2. Hodge theory. The Hodge structure

\[ H_{cusp}^1(\mathcal{M}_{1,1}, S^{2n}\mathbb{H}) = H^{2n+1,0} \oplus H^{0,2n+1}. \]

has a description in terms of modular symbols. The underlying \( \mathbb{Q} \) vector space is the set of \( r(a, b) \in S^{2n}H_\mathbb{Q} \) that satisfy (17.2), modulo \( a^{2n} - b^{2n} \); the Hodge filtration is given by

\[ H^{2n+1,0} = F^{2n+1}H_{cusp}^1(\mathcal{M}_{1,1}, S^{2n}\mathbb{H}) = \{ r_f(a, b) : f \in M_{2n+2}\} / C(a^{2n} - b^{2n}). \]

There is more structure. Each element \( r(a, b) \) of \( S^{2n}H \) can be written in the form

\[ r(a, b) = r^+(a, b) + r^-(a, b), \]

where \( r^+(a, b) \) is the sum of the terms involving only even powers of \( a \) and \( b \) and \( r^-(a, b) \) is the sum of the terms of odd degree.

If \( f \) has real Fourier coefficients (e.g., \( f \in \mathcal{B}_{2n+2} \)), then

\[ r_f(a, b) = r^+_f(a, b) + ir^-_f(a, b), \]

where \( r^+_f(a, b) \) are real. Since the cocycle corresponding to \( \bar{f} \) is \( r^+_f(a, b) - ir^-_f(a, b) \), \( r^+_f(a, b), r^-_f(a, b) \in S^{2n}H_\mathbb{R} \) also satisfy the cocycle condition. Since the classes \( \omega_f(b^{2n}), f \in \mathcal{B}_{2n+2} \) span the cuspidal cohomology, we deduce:

**Proposition 17.4.** If \( r(a, b) \in S^{2n}H_\mathbb{R} \) satisfies the cocycle condition (17.2), then so do \( r^+(a, b) \) and \( r^-(a, b) \). \( \square \)

This gives a decomposition \( V_F = V_F^+ \oplus V_F^- \) of \( V_F := H_{cusp}^1(\mathcal{M}_{1,1}, S^{2n}\mathbb{H}_{/F}) \). Since

\[ H^{2n+1,0}_{cusp}(\mathcal{M}_{1,1}, S^{2n}\mathbb{H}) \cap H^1(\mathcal{M}_{1,1}, S^{2n}\mathbb{H}) = 0 \]

both parts \( r^+_f(a, b) \) of the modular symbol of a cusp form with real Fourier coefficients are non-zero. In particular, for each \( f \in \mathcal{B}_{2n+2} \) we can write

\[ V_{f,\mathbb{R}} = V_{f,\mathbb{R}}^+ \oplus V_{f,\mathbb{R}}^- := \mathbb{R}r^+_f(a, b) \oplus \mathbb{R}r^-_f(a, b). \]

17.2.1. The action of real Frobenius. Complex conjugation (aka "real Frobenius") \( \mathcal{F}_\infty \in \text{Gal}(\mathbb{C}/\mathbb{R}) \) acts on \( \mathcal{M}_{1,1} \) and on the local system \( H_\mathbb{R} \) as we shall explain below. It therefore acts on

\[ V_\mathbb{R} = H_{cusp}^1(\mathcal{M}_{1,1}, S^{2n}\mathbb{H}_{/\mathbb{R}}). \]

In this section we show that its eigenspaces are \( V^\pm_\mathbb{R} \).

The stack \( \mathcal{M}_{1,1}/C \) has a natural real (even \( \mathbb{Q} \)) form, viz, \( \mathbb{G}_m \backslash (\mathbb{A}_\mathbb{R}^2 - D) \), where \( D \) is the discriminant locus \( u^3 - 27v^2 = 0 \) and where \( t \cdot (u, v) = (t^4u, t^6v) \). The universal curve \( \mathcal{E} \) over it also has a natural real form as it is defined over \( \mathbb{R} \). The projection \( \mathcal{E} \to \mathcal{M}_{1,1} \) is invariant under complex conjugation. This implies that \( \mathcal{F}_\infty \) acts on \( H_{\mathbb{R}} \). This action is determined by the action of \( \mathcal{F}_\infty \) on \( H \), the fiber over the tangent vector \( \partial/\partial q \), which is real and therefore fixed by \( \mathcal{F}_\infty \). This induced map is easily seen to be the involution \( \sigma : H \to H \) defined by\(^{19}\)

\[ (17.5) \quad b \to -b, \quad a \to a. \]

\(^{19}\)Here \( H \) is identified with \( H^1(E_{\partial/\partial q}) \) which is isomorphic to \( H_1(E_{\partial/\partial q})(-1) \). So the actions of \( \mathcal{F}_\infty \) on \( H_1(E_{\partial/\partial q}) \) and \( H^1(E_{\partial/\partial q}) \) differ by \(-1\).
The monodromy representation $\text{SL}_2(\mathbb{Z}) \to \text{Aut} H$ of $\mathcal{F}^* \mathbb{H}$ is the standard representation conjugated by $\sigma$. There is therefore an natural action

$$\mathcal{F}_\infty : H^1_{\text{cusp}}(\mathcal{M}_{1,1}, S^{2n} \mathbb{H}_{\mathbb{R}}) \to H^1_{\text{cusp}}(\mathcal{M}_{1,1}, S^{2n} \mathbb{H}_{\mathbb{R}}).$$

Equation (17.5) implies:

**Lemma 17.6.** Real Frobenius acts on $\mathcal{F}_\infty$ on $V_\mathbb{R} = H^1_{\text{cusp}}(\mathcal{M}_{1,1}, S^{2n} \mathbb{H}_{\mathbb{R}})$ by multiplication by 1 on $V_\mathbb{R}^+$ and $-1$ on $V_\mathbb{R}^−$. 

This can also be proved using the description of $F^{2n+1}H^1_{\text{dR}}(\mathcal{M}_{1,1/\mathbb{R}}, S^{2n} \mathcal{H})$ given in [21, Prop. 21.11] and that fact that its image in $H^1_{\text{cusp}}(\mathcal{M}_{1,1}, S^{2n} \mathbb{H}_{\mathbb{C}})$ is invariant under $\mathcal{F}_\infty$.

17.2.2. **Extensions of MHS associated to cusp forms.** Since $V_{f,\mathbb{C}} = V_{f,\mathbb{R}} \oplus F^0 V_f$ when $r < 2n + 2$ and $F^0 V_f(r) = 0$ when $r \geq 2n + 2$, we have

$$(17.7) \quad \text{Ext}^1_{\text{MHS}}(\mathbb{R}, V_f(r)) \cong \begin{cases} 0 & r < 2n + 2, \\ iV_{f,\mathbb{R}} & r \geq 2n + 2 \text{ even}, \\ V_{f,\mathbb{R}} & r \geq 2n + 2 \text{ odd}. \end{cases}$$

We can now compute the $\mathcal{F}_\infty$-invariant extensions:

**Proposition 17.8.** If $f \in \mathfrak{B}_{2n+2}$, then

$$\text{Ext}^1_{\text{MHS}}(\mathbb{R}, V_f(r))^{\mathcal{F}_\infty} \cong \begin{cases} 0 & r < 2n + 2, \\ iV_{f,\mathbb{R}} & r \geq 2n + 2 \text{ even}, \\ V_{f,\mathbb{R}} & r \geq 2n + 2 \text{ odd}. \end{cases}$$

**Proof.** Since $\mathcal{F}_\infty : V_{f,\mathbb{C}} \to V_{f,\mathbb{C}}$ is $\mathbb{C}$-linear, and since twisting by $\mathbb{R}(r)$ multiplies this action by $(-1)^r$, $(iV_{f,\mathbb{R}}(r))^{\mathcal{F}_\infty} = iV_{f,\mathbb{R}}^{(-1)^r}$. The result now follows from (17.7).

So each normalized Hecke eigen cusp form $f \in \mathfrak{B}_{2n+2}$ determines an element of $\text{Ext}^1_{\text{MHS}}(\mathbb{R}, V_f(r))^{\mathcal{F}_\infty}$ for each $r \geq 2n + 2$. Namely, the extension corresponding to $iV_{f,\mathbb{R}}(a, b) \in iV_{f,\mathbb{R}}$ when $r$ is even, and $V_{f,\mathbb{R}}(a, b) \in V_{f,\mathbb{R}}$ when $r$ is odd.

17.3. **Pollack’s quadratic relations.** Motivic considerations [24] (see Section 20) suggest that $w_{2n}^{\mathfrak{B}_n}$ is not free and that a minimal set of relations that hold between the $\mathbf{e}_{2n} \cdot \mathbf{e}_{2n}$ are parametrized by cusp forms. In fact, each cusp form should determine relations between the $\mathbf{e}_{2n} \cdot \mathbf{e}_{2n}$ of every degree $\geq 2$. (For this purpose, $\mathbf{e}_0$ is considered to have degree 1.) One way to guess such relations is to find relations that hold between their images $\mathbf{e}_{2n} \cdot \mathbf{e}_{2n}$ in $\text{Der} \mathfrak{G}_{\mathbb{W}} \mathfrak{P} \cong \text{Der} \mathbb{L}(H)$.\footnote{Since $\mathfrak{G}_{\mathbb{W}}$ is exact, one neither gains nor loses relations in the associated graded.}

In his undergraduate thesis [36], Pollack found a complete set of quadratic relations that hold between the $\mathbf{e}_{2n}$, and found relations of all degrees $\geq 2$ that hold between the $\mathbf{e}_{2n} \cdot \mathbf{e}_{2n}$ modulo a certain filtration of $\text{Der} \mathbb{L}(H)$. Here we state his quadratic relations.

**Theorem 17.9** (Pollack [36, Thm. 2]). The relation

$$\sum_{\substack{j+k=n \\ j,k>0}} c_j[\mathbf{e}_{2j+2}, \mathbf{e}_{2k+2}] = 0$$

The Hodge-de Rham Theory of Modular Groups 65

\[ \]
holds in $\text{Der} \mathbb{L}(H)$ if and only if there is a cusp form $f$ of weight $2n + 2$ whose modular symbol is

$$r_f^+ (a, b) = \sum_{j + k = n \atop j, k \geq 0} c_j a^{2j} b^{2n - 2j}.$$

In view of Theorem 15.7, this suggests each cusp form of weight $2n + 2$ with $r_f^+ (a, b) = \sum_{j + k = n \atop j, k \geq 0} c_j a^{2j} b^{2n - 2j}$ might determine a relation

$$(17.10) \quad \sum_{j + k = n \atop j, k > 0} c_j (2j)! (2k)! [e_{2j + 2}, e_{2k + 2}] = 0$$

in $\text{Gr}_W u^e_{\mathbb{R}}$ and that these relations are connected with $\text{Ext}^1_{\text{MHS}} (R, V_f (2r))$ for appropriate $r > 0$. In the remaining sections, we show that Pollack’s relations do indeed lift to relations in $\text{Gr}_W u^e_{\mathbb{R}}$ and explain the connection to extensions of MHS related to cusp forms. In preparation for proving this, we restate Pollack’s result in cohomological terms.

We let the base point be $\bar{v} = \partial / \partial q$, although any base point will do. Denote the image of the monodromy homomorphism $g \to \text{Der} \mathfrak{p}$ by $\mathfrak{h}$ and its pronilpotent radical by $\mathfrak{n}$. Since the monodromy homomorphism is a morphism of MHS, $\mathfrak{h}$ and $\mathfrak{n}$ have natural MHSs. Since it factors through $\mathfrak{g}^e_{\mathbb{R}}$,

$$H_1 (\mathfrak{n}) \cong \bigoplus_{n > 0} S^{2n} (\epsilon_{2n + 2}) \cong \bigoplus_{n > 0} S^{2n} H (2n + 1).$$

This implies that

$$H^1 (\mathfrak{h}, S^{2n} H (2n + 1)) = \text{Hom}_{\text{SL}(H)} (H_1 (\mathfrak{n}), S^n H) (2n + 1) \cong \mathbb{Q}(0).$$

Regard $S^{2m} H = S^{2m} (b^{2m})$. Let $\hat{e}_{2m}$ be the element of

$$H^1 (\mathfrak{h}, S^{2m} H) \cong \text{Hom}_{\text{SL}(H)} (H_1 (\mathfrak{u}), S^{2m} H)$$

that takes the class of $e_{2m + 2}$ to $b^{2m}$.

The standard duality (Prop. 2.2) between quadratic relations in $\mathfrak{n}$ and the cup product $H^1 (\mathfrak{n}) \otimes H^1 (\mathfrak{n}) \to H^2 (\mathfrak{n})$ gives the following dual version of Pollack’s quadratic relations.

**Proposition 17.11.** There is an inclusion

$$\bigoplus_{n > 0} H^1_{\text{cusp}} (M_{1, 1}, S^{2n} H \mathbb{Q})^F_{\mathbb{R}} \otimes \mathbb{Q}(-2n - 2) \hookrightarrow H^2 (\mathfrak{h}, S^{2n} H).$$

which is a morphism of MHS when $H^1_{\text{cusp}} (M_{1, 1}, S^{2n} H \mathbb{Q})^F_{\mathbb{R}}$ is regarded as a HS of type $(0, 0)$. After tensoring with $\mathbb{R}$, it gives an inclusion

$$\bigoplus_{n > 0} \bigoplus_{f \in \mathfrak{B}_{2n + 2}} \mathbb{R}(-2n - 2) \hookrightarrow H^2 (\mathfrak{h}, S^{2n} H \mathbb{R}).$$

The generator of $\mathbb{R}(-2n - 2)$ corresponding to $f \in \mathfrak{B}_{2n + 2}$ will be denoted by $z_f$. When $j + k = n$, the cup product

$$H^1 (\mathfrak{h}, S^{2j} H (2j + 1)) \otimes H^1 (\mathfrak{h}, S^{2k} H (2k + 1)) \to H^2 (\mathfrak{h}, S^{2n} H (2n + 2))$$

is given by

$$\hat{e}_{2j} \otimes \hat{e}_{2k} \to \sum_{f \in \mathfrak{B}_{2n + 2}} c_{j, k} (f) z_f$$

where $r_f^+ (a, b) = \sum_{j + k = n} c_{j, k} (f) a^{2j} b^{2k}$. 
Remark 17.12. The occurrence of cusp forms here (without their associated Hodge structure) should be related to, and may help explain, the appearance of modular and cusp forms in the work of Conant, Kassabov and Vogtmann [9, 10, 8] on the \( \text{Sp}(H) \)-representation theory of the derivation algebra of a once puncture Riemann surface \( S \) of genus \( g \gg 0 \). Here \( H \) denotes \( H_1(S) \).

18. Deligne Cohomology and Extensions of VMHS

The relations that hold in \( u^n_{x} \) are controlled by relations in the Yoneda ext groups of the category \( \text{MH}_S(M_{1,1}, \mathbb{H}) \). In this section, we sketch the relationship between Deligne cohomology of the relative completion of the fundamental group of an affine curve \( C' = C - D \) and Yoneda ext groups in the categories \( \text{MH}_S(C', \mathbb{H}) \). This generalizes the results of [5] that hold in the unipotent case. We will work in the category of \( \mathbb{Q} \)-MH, although the discussion remains valid in the category of \( \mathbb{R} \)-MH.

18.1. Deligne-Beilinson cohomology of a curve. Let \( \mathcal{V} \) a PVHS over the affine (orbi) curve \( C' = C - D \). The Deligne-Beilinson cohomology \( H^*_B(C', \mathcal{V}) \) is the cohomology of the complex

\[
\text{cone}(\mathcal{F}_0 W_0 \text{Dec}_W K^*_B(C, D; \mathcal{V}) \oplus W_0 \text{Dec}_W K^*_Q(C, D; \mathcal{V})) \rightarrow W_0 \text{Dec}_W K^*_B(C, D; \mathcal{V})[-1].
\]

Here \( \text{Dec}_W \) is Deligne’s filtration decalé functor (with respect to \( W_* \)), which is defined in [11, §1.3]. The DB-cohomology fits in an exact sequence

\[
0 \rightarrow \text{Ext}^1_{\text{MH}_S} (\mathbb{Q}, H^{j-1}(C', \mathcal{V})) \rightarrow H^j_B(C', \mathcal{V}) \rightarrow \text{Hom}_{\text{MH}_S} (\mathbb{Q}, H^j(X, \mathcal{V})) \rightarrow 0.
\]

Deligne-Beilinson cohomology of a higher dimensional variety \( X = \mathcal{X} - D \) with coefficients in a PVHS \( \mathcal{V} \) can be defined using Saito’s mixed Hodge complex that generalizes Zucker’s.

The next result follows directly from the Manin-Drinfeld Theorem (Thm. 11.5) using the exact sequence (18.1).

Proposition 18.2. The DB cohomology \( H^j_B(M_{1,1}, S^m \mathbb{H}(r)) \) vanishes when \( m \) is odd and when \( j > 2 \). When \( j = 1 \) it vanishes except when \( m = 2n \) and \( r = 2n + 1 \), in which case it is isomorphic to \( \mathbb{Q} \). When \( j = 2 \)

\[
H^2_B(M_{1,1}, S^{2n} \mathbb{H}(r)) = \text{Ext}^1_{\text{MH}_S} (\mathbb{Q}, H^1(M_{1,1}, S^{2n} \mathbb{H}(r)))
\]

\[
\cong \text{Ext}^1_{\text{MH}_S} (\mathbb{Q}, \mathbb{Q}(r - 2n - 1)) \oplus \bigoplus_{f \in \mathcal{B}_{2n+2}} \text{Ext}^1_{\text{MH}_S} (\mathbb{Q}, \mathbb{M}_f(r))
\]

where \( f \) ranges over the equivalence classes of \( f \in \mathcal{B}_{2n+2} \). \( \square \)

As explained in Section 17.2.1, the real Frobenius \( \mathcal{F}_\infty \) acts on \( M_{1,1} \) and on the local system \( \mathbb{H} \). These induce an action on the complex used to compute \( H^*_B(M_{1,1}, S^{2n} \mathbb{H}(r)) \) and thus on the Deligne cohomology itself.

Corollary 18.3. For all \( n > 0 \) and \( r \in \mathbb{Z} \), there are natural \( \mathcal{F}_\infty \) equivariant isomorphisms

\[
H^2_B(M_{1,1}, S^{2n} \mathbb{H}(r)) \cong \text{Ext}^1_{\text{MH}_S} (\mathbb{R}, \mathbb{R}(r - 2n - 1)) \oplus \bigoplus_{f \in \mathcal{B}_{2n+2}} \text{Ext}^1_{\text{MH}_S} (\mathbb{R}, V_f(r)).
\]
These vanish when \( r < 2n + 2 \). The first term in the last line corresponds to the Eisenstein series \( G_{2n+2} \).

18.2. Deligne-Beilinson cohomology of a Lie algebra. Suppose that \( \mathfrak{h} \) is a Lie algebra in the category of pro-MHS. Denote the category of continuous Hodge representations of \( \mathfrak{h} \) by \( \text{HRep}(\mathfrak{h}) \). Suppose that \( V \) is a Hodge representation of \( \mathfrak{h} \).

The complex \( C^\bullet(h, V) \) of Chevalley-Eilenberg cochains of \( \mathfrak{h} \) with coefficients in \( V \) (cf. Section 2.1) is a complex in the category of ind-MHS.

**Definition 18.4.** The Deligne cohomology \( H^*_D(h, V) \) is defined to be the cohomology of the complex

\[
\text{cone}(F^0W_0C^\bullet(h, V)_C \oplus W_0C^\bullet(h, V)_Q \to W_0C^\bullet(h, V)_C)[-1].
\]

Denote the MHS \( \mathbb{Q}(0) \) by \( \mathbb{Q} \). The following result follows from the long exact sequence of a cone and the standard description

\[
\text{Ext}^1_{\text{MHS}}(\mathbb{Q}, A) \cong W_0A_C/(F^0W_0A_C + W_0A_Q)
\]

of the extension group in the category MHS of MHS.

**Proposition 18.5.** For all \( j \geq 0 \), there is a short exact sequence

\[
0 \to \text{Ext}^1_{\text{MHS}}(\mathbb{Q}, H^{j-1}(h, V)) \to H^j_D(h, V) \to \text{Hom}_{\text{MHS}}(\mathbb{Q}, H^j(h, V)) \to 0.
\]

The following result is proved, using an argument similar to the proof of the unipotent version [5, Thm. 11.5].

**Proposition 18.6.** For all objects \( V \) of \( \text{HRep}(\mathfrak{h}) \), there is a natural isomorphism

\[
\text{Ext}^*_{\text{HRep}(\mathfrak{h})}(\mathbb{Q}, V) \cong H^*_D(h, V).
\]

These isomorphisms are compatible with the natural products

\[
\text{Ext}^*_{\text{HRep}(\mathfrak{h})}(\mathbb{Q}, V_1) \otimes \text{Ext}^*_{\text{HRep}(\mathfrak{h})}(\mathbb{Q}, V_2) \to \text{Ext}^*_{\text{HRep}(\mathfrak{h})}(\mathbb{Q}, V_1 \otimes V_2)
\]

and

\[
H^*_D(h, V_1) \otimes H^*_D(h, V_2) \to H^*_D(h, V_1 \otimes V_2)
\]

for all objects \( V_1 \) and \( V_2 \) of \( \text{HRep}(\mathfrak{h}) \).

For later use we record:

**Lemma 18.7.** If \( \mathfrak{g} \) is an extension \( 0 \to \mathfrak{u} \to \mathfrak{g} \to \mathfrak{r} \to 0 \) of Lie algebras, where \( \mathfrak{r} \) is semi-simple and \( \mathfrak{u} \) is pronilpotent, then

\[
H^*(\mathfrak{g}, V) \cong [H^*(\mathfrak{u}) \otimes V]^\mathfrak{r}
\]

for all \( \mathfrak{r} \)-modules \( V \). In particular, if \( \mathfrak{u} \) is free, then \( H^j(\mathfrak{g}, V) \) vanishes when \( j > 1 \).

18.3. Extensions of VMHS over curves. Suppose that \( \mathbb{H} \) is a PVHS over \( C' \).

Fix a base point \( x \in C' \) and let \( R_x \) be the Zariski closure of the monodromy action \( \pi_1(C', x) \to \text{Aut}(H_x) \). Denote the completion of \( \pi_1(X, x) \) with respect to \( \pi_1(C', x) \to R_x \) by \( \mathcal{G}_x \) and its Lie algebra by \( \mathfrak{g}_x \). For simplicity, we suppose that \( R_x \) (and hence \( \mathcal{G}_x \)) is a connected and simply connected algebraic group. With these assumptions, the categories \( \text{HRep}(\mathcal{G}_x) \) and \( \text{HRep}(\mathfrak{g}_x) \) are isomorphic. Theorem 8.2 implies that the category \( \text{MHS}(C', \mathbb{H}) \) is equivalent to \( \text{HRep}(\mathfrak{g}_x) \). Proposition 18.6 and the exact sequences (18.1) and its analogue in Prop. 18.5 imply that there is a natural isomorphism

\[
\text{Ext}^*_{\text{MHS}(C', \mathbb{H})}(\mathbb{Q}, V) \cong H^*_D(\mathfrak{g}_x, V_x).
\]

Even more is true:
Theorem 18.8. If \( \mathbb{V} \) is an object of \( \text{MHS}(C', \mathbb{H}) \), then there are natural isomorphisms
\[
\text{Ext}^\bullet_{\text{MHS}(C', \mathbb{H})}(\mathbb{Q}, \mathbb{V}) \cong H^\bullet_D(\mathfrak{g}_x, V_x) \xrightarrow{\sim} H^\bullet_D(C', \mathbb{V})
\]
where \( V_x \) denotes the fiber of \( \mathbb{V} \) over the base point \( x \). These isomorphism is compatible with the natural products.\(^{21}\)

Sketch of Proof. The proof is a generalization of the proof of the corresponding statement [5, Thm. 11.8] in the unipotent case. Let \( \Omega \in F^0 W_{-1} K^1(C, D; \mathfrak{u}) \) be a 1-form as in Section 7.3. A modification of the differential graded algebra map
\[
\theta_\Omega : C^\bullet(\mathfrak{g}_x, V_x) \to \text{Dec}_W K^\bullet(C, D; \mathbb{V})
\]
constructed in Section 4.2 and at the end of the proof of Theorem 7.16 induces a morphism of mixed Hodge complexes, which induces a homomorphism
\[
H^\bullet_D(\mathfrak{g}_x, V_x) \to H^\bullet_D(C', \mathbb{V})
\]
that is compatible with products. It is an isomorphism because the homomorphism (3.4) is an isomorphism of MHS (cf. Section 3.4.2 and Cor. 3.9).

Denote the category of admissible variations of MHS over \( C' \) by \( \text{MHS}(C') \). Since the Deligne cohomology \( H^\bullet_D(C', \mathbb{V}) \) does not depend on the choice of the basic variation \( \mathbb{H} \) with \( \mathbb{V} \in \text{MHS}(C', \mathbb{H}) \), we conclude:

Corollary 18.9. For all admissible variations of MHS over \( C' \), there is a natural isomorphism
\[
\text{Ext}^\bullet_{\text{MHS}(C')}(\mathbb{Q}, \mathbb{V}) \cong H^\bullet_D(C', \mathbb{V})
\]
that is compatible with products.

18.4. Extensions of variations of MHS over modular curves. Suppose that \( \Gamma \) is a congruence subgroup of \( \text{SL}_2(\mathbb{Z}) \). The following result follows from Corollary 18.9 and the Manin-Drinfeld Theorem (Thm. 11.5).

Proposition 18.10. If \( m > 0 \) and \( A \) is a Hodge structure, then
\[
\text{Ext}^1_{\text{MHS}(\Gamma)}(\mathbb{Q}, A \otimes S^m \mathbb{H}) \cong \text{Hom}_{\text{MHS}}(\mathbb{Q}, A \otimes H^1(X_\Gamma, S^m \mathbb{H})).
\]
When \( m = 0 \), \( \text{Ext}^1_{\text{MHS}(\Gamma)}(\mathbb{Q}, A) = \text{Ext}^1_{\text{MHS}}(\mathbb{Q}, A) \). If \( A \) is a simple \( \mathbb{Q} \)-HS, then \( \text{Ext}^1_{\text{MHS}(\Gamma)}(\mathbb{Q}, A \otimes S^m \mathbb{H}) \) is non-zero if and only if either \( A = \mathbb{Q}(m + 1) \) or \( A \cong M_f(m + 1) \) for some Hecke eigen cusp form \( f \) in \( \mathfrak{M}_{m+2}(\Gamma) \).

This result can be interpreted as a computation of the group of normal functions (tensored with \( \mathbb{Q} \)) over \( X_\Gamma \) associated to a PVHS of the form \( \mathbb{V} = A \otimes S^m \mathbb{H} \). These are holomorphic sections of the bundle of intermediate jacobians associated to \( \mathbb{V} \). The group of normal functions (essentially by definition) is isomorphic to \( \text{Ext}^1_{\text{MHS}(\Gamma)}(\mathbb{Z}, \mathbb{V}) \). The normal functions constructed in Section 13.4 generate all simple extensions and normal functions in \( \text{MHS}(X_\Gamma, \mathbb{H}) \).

\(^{21}\)There is a more general result that applies when \( C' \) is replaced by a smooth variety \( X \) of arbitrary dimension. In that case, there is a natural homomorphism \( H^\bullet_S(\mathfrak{g}_x, V_x)^{ρ_0(R)} \to H^\bullet_S(X, \mathbb{V}) \) that is an isomorphism in degrees \( \leq 1 \) and injective in degree 2.
19. Cup Products and Relations in $\mathfrak{u}^{\text{eis}}$

In this section we show that Pollack’s quadratic relations lift to relations in $\mathfrak{u}^{\text{eis}}$. In particular, we show that $\mathfrak{u}^{\text{eis}}$ is not free. Throughout, the base point is $\vec{v} = \partial/\partial q$, although most of the arguments are valid with any base point. As before, $H$ denotes the fiber of $\mathfrak{F}$ over $\vec{v}$. In this setup, $w = 2\pi b$. We will omit the base point from the notation.

Recall from Section 17.3 that $\mathfrak{h}$ denotes the image of the monodromy homomorphism $\mathfrak{g} \to \text{Der} \mathfrak{p}$. As before, we take $S^{2m} H = S^{2m}(\mathfrak{h}^{2m})$. Let $\mathfrak{e}_{2m}$ be the element of

$$H^1(\mathfrak{g}, S^{2m} H) \cong \text{Hom}_{\text{SL}(H)}(H_1(\mathfrak{u}, S^{2m} H))$$

that takes the class of $\mathfrak{e}_{2m+2}$ to $\mathfrak{b}^{2m}$.

Recall that the real Frobenius $\mathcal{F}_\infty$ acts on $H^\bullet_\mathfrak{d} (\mathcal{M}_{1,1}, S^{2n} \mathbb{H}(r))$.

**Lemma 19.1.** For all $m > 0$, the homomorphisms $\mathfrak{g} \to \mathfrak{g}^{\text{eis}} \to \mathfrak{h}$ induce isomorphisms

$$H_D^1(\mathfrak{h}, S^{2m} \mathbb{H}(2m + 1)) \cong H_D^1(\mathfrak{g}^{\text{eis}}, S^{2m} \mathbb{H}(2m + 1))$$

Each of these groups is a 1-dimensional $\mathbb{Q}$ vector space. The first is spanned by $(2\pi i)^{2n+1} \mathfrak{e}_{2m+2}$, the last by $(2\pi i)^{2n+1} \mathfrak{e}_{2m+2}$. The isomorphism identifies $\mathfrak{e}_{2m+2}$ with $(2m)! \mathfrak{e}_{2m+2}/2$.

**Proof.** Lemma 18.7 implies that, for all $n > 0$, each of the groups

$$H^1(\mathfrak{h}, S^{2n} H), \quad H^1(\mathfrak{g}^{\text{eis}}, S^{2n} H), \quad H^1(\mathfrak{g}^{\text{eis}}, S^{2n} H)$$

is isomorphic to $\mathbb{Q}(-2n - 1)$ and that left hand group is generated by $\mathfrak{e}_{2n+2}$ and the right two groups by $\mathfrak{e}_{2n+2}$. Theorem 15.7 implies that the projections $\mathfrak{g} \to \mathfrak{g}^{\text{eis}} \to \mathfrak{h}$ take $\mathfrak{e}_{2m+2}$ to $(2n)! \mathfrak{e}_{2m+2}/2$, so that the homomorphisms induced by the projections are isomorphisms.

Proposition 18.5 implies that the projections $\mathfrak{g} \to \mathfrak{g}^{\text{eis}} \to \mathfrak{h}$ induce isomorphisms

$$H_D^1(\mathfrak{g}^{\text{eis}}, S^{2n} \mathbb{H}(2n + 1)) \cong H_D^1(\mathfrak{g}, S^{2n} \mathbb{H}(2n + 1)) \cong \mathbb{Q}$$

for all $n > 0$. The corresponding class in Deligne cohomology is easily seen to be $\mathcal{F}_\infty$ invariant. 

**Lemma 19.2.** There is a natural inclusion

$$iH^1_{\text{cusp}}(\mathcal{M}_{1,1}, S^{2m} \mathbb{H}_R) \mathcal{F}_\infty \hookrightarrow H_D^1(\mathfrak{h}, S^{2m} H(2m + 2))$$

**Proof.** Since $\mathfrak{u}$ is free, Lemma 18.7 implies that $H^2(\mathfrak{g}, S^m H)$ vanishes for all $m > 0$. The result follows from Proposition 18.5, the computation (Thm. 7.16) of $H^1(\mathfrak{u})$ and the isomorphism

$$\text{Ext}^1_{\text{MHS}}(\mathbb{R}, H^1_{\text{cusp}}(\mathcal{M}_{1,1}, S^{2m} \mathbb{H}_R)) \mathcal{F}_\infty \cong iH^1_{\text{cusp}}(\mathcal{M}_{1,1}, S^{2m} \mathbb{H}_R) \mathcal{F}_\infty = \bigoplus_{f \in \mathfrak{B}_{2m+2}} iV_f^+$$

which is well defined up to an even power of $2\pi i$ that depends upon the choice of the first isomorphism. 

By Corollary 18.3, there is an $\mathcal{F}_\infty$ invariant projection
\[ H^2_D(M_{1,1}, S^{2n}\mathbb{H}_R(2n + 2)) \rightarrow \text{Ext}^1_{\text{MHS}}(\mathbb{R}, V_f(2n + 2)). \]
The following computation is the key to proving that Pollack’s quadratic relations are motivic.

**Theorem 19.3** (Terasoma [46, Thm. 7.3]). If $j, k > 0$ and $n = j + k$, then the image of the cup product
\[ H^1_D(M_{1,1}, S^{2j}\mathbb{H}_R(2j + 1)) \otimes H^1_D(M_{1,1}, S^{2k}\mathbb{H}_R(2k + 1)) \rightarrow H^2_D(M_{1,1}, S^{2n}\mathbb{H}_R(2n + 2)) \]
is non-zero. More precisely, the composition of the cup product with the projection
\[ H^2_D(M_{1,1}, S^{2n}\mathbb{H}_R(2n + 2)) \rightarrow \text{Ext}^1_{\text{MHS}}(\mathbb{R}, V_f(2n + 2))^\infty \cong V^*_{f,R} \]
is non-trivial for all $f \in \mathbb{B}_{2n+2}$. □

A direct consequence is that Pollack’s quadratic relations hold in $u^{\text{eis}}$. 

**Theorem 19.4.** Pollack’s quadratic relations (17.10) hold in $G_{1,1}^* u^{\text{eis}}$. In particular, the pronipotent radical $u^{\text{eis}}$ of $\mathfrak{g}^{\text{eis}}$ is not free.

**Proof.** Suppose that $j, k > 0$. Set $n = j + k$. Since $H^\bullet(\mathfrak{g}^{\text{eis}}, S^m H) = [H^\bullet(u^{\text{eis}}) \otimes S^m H]^{\text{SL}_2(H)}$ and since each $H^1(\mathfrak{g}^{\text{eis}}, S^{2j} H)$ is 1-dimensional, it suffices to prove that the image of the cup product
\[ H^1(\mathfrak{g}^{\text{eis}}, S^{2j} H) \otimes H^1(\mathfrak{g}^{\text{eis}}, S^{2k} H) \rightarrow H^2(\mathfrak{g}^{\text{eis}}, S^{2n} H) \]
is non-trivial. To prove this, we use Deligne cohomology. We use the notation
\[ \Gamma V := \text{Hom}_{\text{MHS}}(\mathbb{Q}, V) \]
to denote the set of Hodge classes of type $(0, 0)$ of a MHS $V$.

Naturality and Proposition 18.5 imply that there is a commutative diagram
\[ \begin{array}{ccc}
H^2_D(h, S^{2n+2} H(2n + 2)) & \rightarrow & H^2_D(\mathfrak{g}^{\text{eis}}, S^{2n+2} H(2n + 2)) \\
\downarrow & & \downarrow \\
\Gamma H^2(h, S^{2n+2} H(2n + 2)) & \rightarrow & \Gamma H^2(\mathfrak{g}^{\text{eis}}, S^{2n+2} H(2n + 2)) \\
\text{Ext}^1(\mathbb{Q}, H^*_\text{unip}(M_{1,1}, S^{2n+2} H(2n + 2))) & \rightarrow & \text{Ext}^1(\mathbb{Q}, H^*_\text{unip}(M_{1,1}, S^{2n+2} H(2n + 2)))
\end{array} \]
where the vertical maps are surjective. Theorem 19.3 and Proposition 17.11 imply that the image of the cup product
\[ \mathbb{Q} \cong H^1_D(\mathfrak{g}^{\text{eis}}, S^{2j} H(2j + 1)) \otimes H^1_D(\mathfrak{g}^{\text{eis}}, S^{2k} H(2k + 1)) \rightarrow H^2_D(\mathfrak{g}^{\text{eis}}, S^{2n+2} H(2n + 2)) \]
is non-zero in both groups of the left and right columns. It is therefore non-zero in $H^2(\mathfrak{g}^{\text{eis}}, S^{2n} H)$. □

Much of the discussion in this section can be generalized to modular curves $X_\Gamma$ where $\Gamma$ is a congruence subgroup of $\text{SL}_2(\mathbb{Z})$. In particular, the pronipotent radical $u^{\text{eis}}_\Gamma$ is not free for all congruence subgroups.

**Remark 19.5.** This result implies that, when $\Gamma = \text{SL}_2(\mathbb{Z})$, Manin’s quotient $u_B$ of $u_\Gamma$ (cf. 13.2) is not a quotient of $u_\Gamma$ in the category of Lie algebras with a MHS. If it were, it would $u^{\text{eis}}_B$. But since $u_B$ is free, and since $u^{\text{eis}}_1$ is not, $\mathcal{U}_B \rightarrow \mathcal{U}^{\text{eis}}_B$ cannot be an isomorphism.
20. Motivic Context

Here we briefly sketch a conjectural motivic explanation for the relations in \( v^{\text{eis}} \). More details can be found in [24] where a tannakian category \( \text{MEM} \) of universal mixed elliptic motives over Spec \( \mathbb{Z} \) is constructed. Its fundamental group \( \pi_1(\text{MEM}) \) is an extension of \( GL(H) \) by a prounipotent group \( \mathcal{U}_{\text{MEM}} \). Denote their Lie algebras by \( \mathfrak{g}_{\text{MEM}} \) and \( \mathfrak{u}_{\text{MEM}} \). These are Lie algebras in the category \( \text{MTM} \) of mixed Tate motives over Spec \( \mathbb{Z} \). In particular, each possess a MHS and, after tensoring with \( \mathbb{Q}_\ell \), an action of the absolute Galois group \( G_\mathbb{Q} := \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \) that is unramified at all primes \( p \neq \ell \) and crystalline at \( \ell \).

Here we regard \( \mathcal{M}_{1,1} \) as a stack over Spec \( \mathbb{Z} \). The associated analytic orbifold \( \text{SL}_2(\mathbb{Z}) \backslash \mathfrak{h} \) will be denoted by \( \mathcal{M}_{1,1}^{\text{an}} \). The base point \( \vec{v} = \partial / \partial q \) is integrally defined; the pair \( (\mathcal{M}_{1,1}/\mathbb{Z}, \vec{v}) \) has everywhere good reduction in the sense that, for all prime numbers \( p \), \( \mathcal{M}_{1,1}/\mathbb{Z}_p \) is smooth and \( \vec{v} \) is non-zero in \( \mathcal{M}_{1,1}/\mathbb{Z}_p \). In all cases \( H \) will denote the fiber of \( \mathbb{H} = \mathbb{H}_\mathbb{Q} \) over \( \vec{v} \).

In addition to the relative completion \( \mathcal{G} \) of \( \pi_1(\mathcal{M}_{1,1}^{\text{an}}, \vec{v}) \) and its Eisenstein quotient \( \mathcal{G}^{\text{eis}} \), there is, for each prime number \( \ell \), the \( \ell \)-adic weighted completion (more accurately, the \( \ell \)-adic crystalline completion) \( \mathcal{G}^{\text{wtd},\ell} \) of \( \pi_1(\mathcal{M}_{1,1}/\mathbb{Z}[1/\ell], \vec{v}) \) with respect to the natural homomorphism to \( GL(H_{\mathbb{Q}_\ell}) \). (See [22, 23] for definitions.)

There are natural homomorphisms

\[
\pi_1(\text{MEM}) \to \pi_1(\text{MTM}) \to \mathbb{G}_m.
\]

The first corresponds to pulling back mixed Tate motives along the structure morphism \( \mathcal{M}_{1,1} \to \text{Spec } \mathbb{Z} \), the second to the inclusion of the pure mixed Tate motives into \( \text{MTM} \). Denote the kernel of \( \pi_1(\text{MEM}) \to \pi_1(\text{MTM}) \) by \( \pi_1(\text{MEM})^{\text{geom}} \). There is a commutative diagram

\[
\begin{array}{cccccc}
1 & \longrightarrow & \pi_1^{\text{geom}}(\text{MEM}) & \longrightarrow & \pi_1(\text{MEM}) & \longrightarrow & \pi_1(\text{MTM}) & \longrightarrow & 1 \\
1 \downarrow & & \downarrow & & \downarrow & & \downarrow & \\
1 & \longrightarrow & \text{SL}(H) & \longrightarrow & GL(H) & \longrightarrow & \mathbb{G}_m & \longrightarrow & 1.
\end{array}
\]

Each of the vertical homomorphisms has prounipotent kernel. The natural homomorphisms

\[
(20.1) \quad \pi_1(\mathcal{M}_{1,1}^{\text{an}}, \vec{v}) \to \pi_1^{\text{geom}}(\text{MEM})(\mathbb{Q}) \quad \text{and} \quad \pi_1(\mathcal{M}_{1,1}/\mathbb{Z}[1/\ell], \vec{v}) \to \pi_1(\text{MEM})(\mathbb{Q}_\ell)
\]

induce surjective homomorphisms

\[
\mathcal{G}^{\text{eis}} \to \pi_1^{\text{geom}}(\text{MEM}) \quad \text{and} \quad \mathcal{G}^{\text{wtd},\ell} \to \pi_1(\text{MEM}) \otimes \mathbb{Q}_\ell
\]

for all primes \( \ell \). So relations that hold in \( \mathcal{G}^{\text{eis}} \) or \( \mathcal{G}^{\text{wtd},\ell} \) also hold in \( \pi_1(\text{MEM}) \) and are therefore motivic. In particular, Theorem 19.4 implies that Pollack’s relations hold in the Lie algebra of \( \pi_1(\text{MEM}) \) and are therefore motivic.

**Conjecture 20.2** (Hain-Matsumoto [24]). All relations that hold in the prounipotent radical of \( \pi_1(\text{MEM}) \) come from \( \mathcal{G}^{\text{eis}} \) and \( \mathcal{G}^{\text{wtd},\ell} \). More precisely:

(i) The homomorphism \( \mathcal{G}^{\text{eis}} \to \pi_1^{\text{geom}}(\text{MEM}) \) is an isomorphism of \( \mathbb{Q} \)-groups with MHS.

(ii) For all prime numbers \( \ell \), the homomorphism \( \mathcal{G}^{\text{wtd},\ell} \to \pi_1(\text{MEM}) \otimes \mathbb{Q}_\ell \) is an isomorphism.
More optimistically, one can conjecture that the monodromy representations
\[ G \to \text{Aut} \, p \quad \text{and} \quad G^{wtd, \ell} \to \text{Aut} \, p \]
are faithful, where \( p \) denotes the Lie algebra of \( \pi_1^{un}(E, \bar{w}) \) and \( \bar{w} \) is the naturally tangent vector at the identity of the Tate curve. If this is the case, relations in the Lie algebra \( \mathfrak{g}_{\text{MEM}} \) can be computed in \( \text{Der} \, p \).

Conjecture 20.2 is related to standard conjectures in number theory \cite{Kato93} predict that if \( f \in \mathcal{B}_{2n+2} \), then
\[ \dim_{Q} \text{Ext}_{\text{MM}(Z)}^{1} \left( Q, M_{f}(r) \right) = \dim_{Q} \text{Ext}_{\text{MHS}}^{1} \left( \mathbb{R}, M_{f, \mathbb{R}}(r) \right) \]
\[ = \dim_{Q} H^{1}(\text{Spec} \, \mathbb{Z}, M_{f, \ell}(r)) = \begin{cases} 0 & \quad r < 2n + 2, \\ \left[K_{f} : Q\right] & \quad r \geq 2n + 2. \end{cases} \]

More precisely, the regular mappings
\[ \text{reg}_{\text{MHS}} : \text{Ext}_{\text{MM}(Z)}^{1} \left( Q, M_{f}(r) \right) \otimes_{Q} \mathbb{R} \to \text{Ext}_{\text{MHS}}^{1} \left( \mathbb{R}, M_{f, \mathbb{R}}(r) \right) \]
and (for all \( \ell \))
\[ \text{reg}_{\ell} : \text{Ext}_{\text{MM}(Z)}^{1} \left( Q, M_{f}(r) \right) \otimes_{Q} \mathbb{Q}_{\ell} \to H^{1}(\text{Spec} \, \mathbb{Z}, M_{f, \ell}(r)) \]
are isomorphisms. \( \text{22} \)

So Conjecture 20.2 implies that each cusp form \( f \) of weight \( 2n + 2 \) should determine relations of each degree \( \geq 2 \) in \( u^{\text{cis}}, u_{\text{MEM}}, \) etc. Pollack \cite{Pollack99} found such

\( ^{22} \text{Kato} \) [29] has proved the vanishing of \( H^{1}(\text{Spec} \, \mathbb{Z}, S^{2n} H(r)) \) when \( r < 2n + 2 \). Scholl \cite{Scholl90} has proved the surjectivity of the regulators.
relations of all degrees that hold between the $\epsilon_{2n+2}$ in a certain quotient of $\text{Der}_p$ and showed that those of low weight lift to actual relations in $\text{Der}_p$.\footnote{Baumard and Schneps \cite{baumard-schneps} have shown that all of Pollack's truncated cubic relations lift to actual relations in $\text{Der}_p$.}

Denote the category of lisse sheaves of $\mathbb{Q}_\ell$ vector spaces over $\mathcal{M}_{1,1}/\mathbb{Z}[1/\ell]$ that are crystalline at $\ell$ and that are iterated extensions of $S^m H_{\ell}(r)$ by $\mathcal{L}(\mathcal{M}_{1,1})$. This is the étale analogue of $\text{MHS}(\mathcal{M}_{1,1})$. There are realization functors

$$\text{real}_{\text{MHS}}: \text{MEM} \to \text{MHS}(\mathcal{M}_{1,1}) := \text{MHS}(\mathcal{M}_{1,1}^\text{reg}, \mathbb{H})$$

and

$$\text{real}_\ell: \text{MEM} \to \mathcal{L}(\mathcal{M}_{1,1})$$

The relationships between the motivic (conjectural), Hodge and étale versions are summarized in the diagram

$$\begin{align*}
\text{Ext}^1_{\text{MHS}}(\mathbb{R}, M_{f,\ell}(r))^\infty & \xrightarrow{\text{real}_{\text{MHS}}} \text{Ext}^2_{\text{MHS}(\mathcal{M}_{1,1})}(\mathbb{R}, S^{2n} \mathbb{H}(r))^\infty \xrightarrow{\text{real}_{\text{MHS}}} H^2_\text{D}(\mathbb{R}, S^{2n} H)^\infty \\
\text{Ext}^2_{\text{MEM}}(\mathbb{Q}, M_f(r)) & \xrightarrow{\text{real}_\ell} \text{Ext}^2_{\text{MEM}}(\mathbb{Q}, S^{2n} \mathbb{H}(r)) \xrightarrow{\text{real}_\ell} H^2(MEM, S^{2n} \mathbb{H}(r))
\end{align*}$$

in which the top row consists of real vector spaces, the second of $\mathbb{Q}$ vector spaces and the third of $\mathbb{Q}_\ell$ vector spaces.
