Graph states are widely used in quantum information theory, including entanglement theory, quantum error correction, and one-way quantum computing. Graph states have a nice structure related to a certain graph, which is given by either a stabilizer group or an encoding circuit, both can be directly given by the graph. To generalize graph states, whose stabilizer groups are abelian subgroups of the Pauli group, one approach taken is to study non-abelian stabilizers. In this work, we propose to generalize graph states based on the encoding circuit, which is completely determined by the graph and a Hadamard matrix. We study the entanglement structures of these generalized graph states, and show that they are all maximally mixed locally. We also explore the relationship between the equivalence of Hadamard matrices and local equivalence of the corresponding generalized graph states. This leads to a natural generalization of the Pauli \((X,Z)\) pairs, which characterizes the local symmetries of these generalized graph states. Our approach is also naturally generalized to construct graph quantum codes which are beyond stabilizer codes.

I. INTRODUCTION

An undirected graph \(G\) with \(n\) vertices and the edge set \(E(G)\) corresponds to a unique \(n\)-qubit quantum state \(|\psi_G\rangle\), which is called the graph state (corresponding to the graph \(G\)). Graph states are extensively studied and widely used in quantum information theory, due to its nice entanglement structures [1, 2]. Certain kind of graph states (e.g. the cluster states) can be used as resource states for measurement-based quantum computing [3]. And it is known that any stabilizer state is in fact equivalent to some graph states via local Clifford operations [4].

Graph states are also building blocks for a wide class of quantum error-correcting codes. For instance, it is natural to choose the basis of a stabilizer code using stabilizer states. Furthermore, by including ancilla qubits for encoding, graphs can be used to represent stabilizer codes, called the graph codes [5], and any stabilizer code is local Clifford equivalent to some graph code [4]. Going beyond the stabilizer codes, one can use graph states as basis for the so called codeword stabilized quantum codes [6], with which good nonaddictive codes may be constructed.

Graph states are also of interests to many-body physics. They naturally appear as ground states of gapped local Hamiltonians, which are given by commuting local projectors [7]. These states are relatively easy to analyze, and may exhibit interesting properties such as topological orders [8] and symmetry-protected topological orders [9–12], which are beyond the traditional symmetry-breaking orders.

There are two equivalent ways to define \(|\psi_G\rangle\). One is from a stabilizer formalism. That is, for each vertex \(i\) in \(G\), assign a stabilizer generator,

\[ g_i = X_i \prod_{j \in N(i)} Z_j \]  

(1)

where \(X_i\) (\(Z_j\)) is the Pauli \(X\) (\(Z\)) operator acting on the \(i\)th (\(j\)th) qubit, and \(N(i)\) denotes the qubits that are neighbours of \(i\) in graph \(G\). Each \(g_i\) has eigenvalues 1 and \(-1\), and the \(g_i\)s are mutually commuting. Therefore there exists a unique quantum state \(|\psi_G\rangle\) satisfying \(g_i|\psi_G\rangle = |\psi_G\rangle\), i.e. \(|\psi_G\rangle\) is the stabilizer state with the stabilizer group generated by \(g_i\)s.

The other way is given by a circuit \(\mathcal{U}\) that generates \(|\psi_G\rangle\) from the product state \(|0\rangle^{\otimes n}\), i.e. \(\mathcal{U}|0^{\otimes n}\rangle = |\psi_G\rangle\), where

\[ \mathcal{U} = \frac{1}{2^{n/2}} \prod_{ij \in E(G)} C_{ij}^Z H^{\otimes n}. \]  

(2)

Here \(E(G)\) is the edge set of the graph \(G\). \(H\) is the Hadamard matrix

\[ H = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}. \]  

(3)
and $C^Z$ is the two-qubit controlled-Z gate which a diagonal matrix given by

$$C^Z = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}. \quad (4)$$

These two ways are equivalent definitions for $|\psi_G\rangle$ given that

$$U_dZ_dU_d^\dagger = g_i, \; \forall \; i. \quad (5)$$

Graph states has a natural generalization to the qudit case, based on the generalized Pauli operators $X_d, Z_d$ satisfying the commutation relations of a quantum plane \[13\]

$$X_dZ_d = q_dZ_dX_d, \quad (6)$$

where $X_d, Z_d$ are defined by the maps $X_d|i\rangle = |i - 1 \; (\text{mod} \; d)\rangle$, $Z_d|i\rangle = q_d^{|i\rangle\langle i|}$, $i = 0, 1, \ldots, d - 1$, and $q_d = e^{2\pi i/d}$. Based on this, Eq. (11) naturally generalizes to

$$g_i = (X_d)_i^\dagger \prod_{j \in N(i)} (Z_d)_j^\dagger, \quad (7)$$

and $g_i$s are mutually commuting. The corresponding unique qudit graph state, denoted by $|\psi_{G,F_d}\rangle$, is then given by $g_i|\psi_{G,F_d}\rangle = |\psi_{G,F_d}\rangle, \; \forall \; i$. Also, the circuit given in Eq. (2) has a natural generalization by replacing $H$ by the discrete Fourier transform

$$F_d = \sum_{i,j=0}^{d-1} q_d^{ij} |i\rangle\langle j|, \quad (8)$$

and replacing $C^Z$ by its generalized version

$$C^{Z_d} = \sum_{i,j=0}^{d-1} q_d^{ij} |ij\rangle\langle ij|, \quad (9)$$

and naturally

$$U_dZ_dU_d^\dagger = g_i, \; \forall \; i, \quad (10)$$

for

$$U_d = \frac{1}{d^{n/2}} \prod_{ij \in E(G)} C^{Z_d}_{ij} F_d \otimes_n. \quad (11)$$

Recently, there have been considerations to generalize the graph (stabilizer) states beyond the abelian group structure of the Pauli group. One approach is to generalize the stabilizer formalism, by allowing non-commuting stabilizers. This includes the monomial stabilizer states \[14\] and the XS-stabilizer states \[15\], which describes some well-known many-body quantum states, for instance the Affleck-Kennedy-Lieb-Tasaki states \[16\] and the twisted quantum double model states \[17\]. However, because these is no longer a simple relationship between the stabilizers and the circuits (as Eq. (10)), the corresponding ‘stabilizer states’ with non-commuting stabilizers lack a clear graph structure. Another approach is to generalize the Pauli $X$ operators as a certain kind of group action corresponding to an non-abelian group, and together with a generalized controlled-NOT operation, the correspond generalized graph states can then be defined on bipartite graphs which are directed \[18\].

In this work, we propose a generalization of graph states based on Hadamard matrices. On the one hand, this is a very natural generalization, by observing the information ‘encoded’ in Eqs (8)(9). That is, in the circuit $U_d$, if one uses a Hadamard matrix $H$ (to replace $F_d$), then one may further replace $C^{Z_d}$ by some generalized controlled-$Z$ operation which is defined by the entries of $H$. In this sense, our generalization will be based on the circuit approach instead of the stabilizer approach. On the other hand, (complex) Hadamard matrices themselves are of great mathematical interests, which has already been connected to various areas of study in quantum information science \[19–21\].
The advantage of our generalization is its simple description at the first place: given an undirected graph $G$ with $n$ vertices, and an $d \times d$ (symmetric) Hadamard matrix $H$, a unique generalized graph state $|\psi_{G,H}\rangle$ is then defined. We focus on basic properties of these graph states, especially their structures related to the properties of the graph $G$ and the Hadamard matrix $H$.

For basic entanglement properties of $|\psi_{G,H}\rangle$, we show that $|\psi_{G,H}\rangle$ has maximally entangled single particle states regardless of the choice of the graph $G$. And $|\psi_{G,H}\rangle$ has a tensor network representation with tensors directly given by the entries of $H$. If $H$ has a tensor product structure, then $|\psi_{G,H}\rangle$ also has a tensor product structure.

Since one of the most basic properties of Hadamard matrices are their equivalence [21], we explore the relationship between the equivalence of Hadamard matrices and local equivalence of the corresponding graph states. Our main results along this line include the following.

- $|\psi_{G,H}\rangle$ may not be local unitary equivalent to $|\psi_{G,F_n}\rangle$ for some $G$.
- Certain equivalence of $H$ corresponds to the local unitary equivalence of $|\psi_{G,H}\rangle$.
- For any bipartite graph $G$, equivalence of $H$ corresponds to the local unitary equivalence of $|\psi_{G,H}\rangle$.
- Certain symmetry (automorphism) of $H$ corresponds to the local symmetries (stabilizers) of $|\psi_{G,H}\rangle$.

Furthermore, we show that the generalization of the circuit $U_4$ can also be used as an encoding circuit for quantum error-correcting codes, by adding a classical encoder. This leads to non-stabilizer codes, where the effects of some errors are easy to analyze, depending on the structure of $H$.

II. THE GENERALIZED GRAPH STATES

**Definition 1** A complex Hadamard matrix $H$ is a $d \times d$ matrix which satisfies that each matrix element $h_{ij}$ of $H$ for $i, j = 0, 1, \ldots, d - 1$ with $|h_{ij}| = 1$, and

$$H^\dagger H = dI_d,$$

where $I_d$ is the $d \times d$ identity matrix.

We consider a $d \times d$ complex Hadamard matrix $H$ that is symmetric, i.e.

$$H = H^T, \quad H^*H = dI_d. \tag{13}$$

For any quantum state in $\mathbb{C}^d \otimes \mathbb{C}^d$, we define a generalized controlled-$Z$ gate, which is completely determined by $H$. For this reason we write this gate by $C^H$, which is given by

$$C^H |ij\rangle = h_{ij} |ij\rangle. \tag{14}$$

The reason for choosing $H$ symmetric is that $C^H$ does not distinguish the controlled qudit from the target qubit, so one can then define a generalized graph state on an undirected graph, which is given by the following definition.

**Definition 2** For an undirected graph $G$ of $n$ vertices, with vertex set $V(G)$ and edge set $E(G)$. Define a circuit based on the symmetric Hadamard matrix $H$ by

$$U_{G,H} = \frac{1}{d^{n/2}} \prod_{ij \in E(G)} C^H_{ij} H^\otimes n, \tag{15}$$

where $C^H_{ij}$ is the generalized controlled-$Z$ gate acting on the $i, j$th qudits, and the $n$-qudit generalized graph state $|\psi_{G,H}\rangle$ given by

$$|\psi_{G,H}\rangle = U_{G,H} |0\rangle^\otimes n. \tag{16}$$

For $d = 2$ and $H = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$, $|\psi_{G,H}\rangle$ is the usual qubit graph state $|\psi_G\rangle$. And when $H$ is the $d$-point discrete Fourier transform $F_n$, $|\psi_{G,H}\rangle$ is the usual qudit graph state $|\psi_{G,F_n}\rangle$.

We also introduce a graphical way to represent the circuit $U_{G,H}$, which will helps us to visualize/prove some general properties of $|\psi_{G,H}\rangle$. Based on the usual way of drawing a quantum circuit, we further use $H$ representing the unitary transform $\frac{1}{\sqrt{d}} H$, and the black-diamonds to replace the black-dots in the usual controlled-$Z$, to represent the generalized controlled-$Z$, given by $C^H$. As an example, for the triangle graph of Figure 1(e), we have the corresponding circuit for creating $|\psi_{\Delta,H}\rangle$ as given in Figure 2.

In order to discuss the properties of $|\psi_{G,H}\rangle$, we would need the concepts of local equivalence of two quantum states.
Definition 3 Two $n$-qudit quantum states $|\psi_1\rangle$ and $|\psi_2\rangle$ are local unitary (LU) equivalent if there exists a local unitary operator $U = \bigotimes_{i=1}^{n} U_i$, such that $U|\psi_1\rangle = |\psi_2\rangle$, where each $U_i$ is a single-qudit unitary operation.

The single qudit Clifford group is the automorphism group of the qudit Pauli group generated by $X_d$ and $Z_d$.

Definition 4 Two $n$-qudit quantum states $|\psi_1\rangle$ and $|\psi_2\rangle$ are local Clifford (LC) equivalent if there exists a local unitary operator $L = \bigotimes_{i=1}^{n} L_i$, such that $L|\psi_1\rangle = |\psi_2\rangle$, where each $L_i$ is a single-qudit Clifford operation.

III. ENTANGLEMENT PROPERTIES

We discuss basic entanglement properties of $|\psi_{G,H}\rangle$. Denote $\Gamma_i$ the $d \times d$ diagonal matrix whose diagonal elements are the $i$th column of $H$. Denote $|GHZ_{n,d}\rangle$ the $n$-qudit GHZ state, which is given by

$$|GHZ_{n,d}\rangle = \frac{1}{\sqrt{d}} \sum_{i=1}^{d} |ii\ldots i\rangle.$$  \hspace{1cm} (17)

A. The bipartite system

We start to examine the properties of $|\psi_{G,H}\rangle$ for $n = 2$, where the nontrivial graph corresponds to the one given by Figure 1(a). In this case, the corresponding $|\psi_{G,H}\rangle$ is a maximally entangled state. This can be seen from

$$|\psi_{G,H}\rangle = \frac{1}{d} C_{12}^H |0\rangle \otimes |0\rangle = \frac{1}{d} C_{12}^H (\Gamma_1 \otimes \Gamma_1) \sum_{ij} |ij\rangle = (\Gamma_1 \otimes \Gamma_1) \frac{1}{d} C_{12}^H \sum_{ij} |ij\rangle$$

$$= (\Gamma_1 \otimes \Gamma_1) \frac{1}{\sqrt{d}} \sum_i |i\rangle \left( \frac{1}{\sqrt{d}} \sum_j h_{ij} |j\rangle \right) = (\Gamma_1 \otimes \Gamma_1) \frac{1}{\sqrt{d}} \sum_i |i\rangle |\psi_i\rangle.$$

Here the states $|\psi_i\rangle = H|i\rangle = \frac{1}{\sqrt{d}} \sum_j h_{ij} |j\rangle$ are orthonormal ($\langle \psi_i | \psi_j \rangle = \delta_{ij}$) due to the orthogonality of the rows of $H$.
It is obvious that $|\psi_{G,H}\rangle$ is LU equivalent to the state $\frac{1}{\sqrt{d}} \sum_{i} |i\rangle |\psi_{i}\rangle$, which is also a generalized graph state with the same graph but another Hadamard matrix with all 1 elements of the first row/column. In other words, to discuss entanglement properties of $|\psi_{G,H}\rangle$, it suffices to assume $\Gamma_{1} = I$. In fact, this $\Gamma_{1} = I$ assumption is without loss of generality, as in general $|\psi_{G,H}\rangle$ will be LU equivalent another generalized graph state with the same graph whose Hadamard matrix is with all 1 elements of the first row/column (see Lemma 11 and Theorem 14). Therefore, from we will just assume $\Gamma_{1} = I$ for all the Hadamard matrix $H$ in our following discussions.

Furthermore, since we also have (for $\Gamma_{1} = I$)

$$|\psi_{G,H}\rangle = \frac{1}{d} C_{ij}^{H} \sum_{i,j} |ij\rangle = \frac{1}{\sqrt{d}} \left( \frac{1}{\sqrt{d}} \sum_{i,j} H_{ij}|i\rangle \right) |j\rangle = \frac{1}{\sqrt{d}} \sum_{j} |\psi_{j}\rangle |j\rangle,$$

we have that $H \otimes H^{*}$ (or $H^{*} \otimes H$) is a symmetry of $|\psi_{G,H}\rangle$. That is,

$$H \otimes H^{*}|\psi_{G,H}\rangle = |\psi_{G,H}\rangle.$$  \hfill (20)

This shows that $|\psi_{G,H}\rangle$ is a maximally entangled state, which is independent of the choice of $H$. Or in other world, all the $|\psi_{G,H}\rangle$ are local unitary equivalent to each other. This is consistent with the observation that all $|\psi_{G,H}\rangle$ can be used in teleportation and dense-coding schemes [19].

B. Single particle entanglement

For $n = 3$, there are two kinds of connected graphs $G$. The first one has edge set $E(G) = \{(12), (23), \ldots, (1n)\}$. For any single particle reduced density matrix of the 1st qudit is then maximally mixed □.

This property generalizes to multi-qudit case, which is given by the following proposition.

**Proposition 5** If $G$ is an $n$-qudit star-shape graph, i.e. with edge set $E(G) = \{(12), (13), \ldots, (1n)\}$, then $|\psi_{G,H}\rangle$ is LU equivalent to $|\text{GHZ}_{n,d}\rangle$.

**Proof:** Notice that

$$|\psi_{G,H}\rangle = \frac{1}{d^{n/2}} \prod_{i,j \in E(G)} C_{ij}^{H} H^{\otimes n} |0\rangle^{\otimes n}$$

$$= \frac{1}{d^{n/2}} \prod_{i,j \in E(G)} C_{ij}^{H} \sum_{i_1 i_2 \ldots i_n} |i_1 i_2 \ldots i_n\rangle$$

$$= \frac{1}{\sqrt{d}} \sum_{j} |j\rangle |\psi_{j}\rangle \cdots |\psi_{j}\rangle,$$  \hfill (22)

which is LU equivalent to $|\text{GHZ}_{n,d}\rangle$ □.

A direct consequence of Proposition 5 is the following.

**Corollary 6** Any single particle reduced density matrix of $|\psi_{G,H}\rangle$ is maximally mixed for any connected graph $G$.

**Proof:** Denote the vertex set of the graph $G$ by $V(G)$. For any vertex $a \in V(G)$, denote $G_{a}^{*}$ the graph with the same vertices as that of $G$, but only edges $a_j \in E(G)$. Without loss of generality we only consider the case of $a = 1$. Then we have

$$|\psi_{G,H}\rangle = \prod_{i \neq 1, j \in V(G)} C_{ij}^{H} |\psi_{G_{1}^{*},H}\rangle.$$  \hfill (23)

Since $G$ is a connected graph, according to Proposition 5, $|\psi_{G_{1}^{*},H}\rangle$ is LU equivalent to a tensor product of some $|\text{GHZ}_{m,d}\rangle$s (for $m \leq n$). Furthermore, $\prod_{i \neq 1, j \in V(G)} C_{ij}^{H}$ does not act on the 1st qudit. Consequently, the single particle reduced density matrix of the 1st qudit is then maximally mixed □.
C. The tensor network representation

It is known that the graph states are ‘finitely correlated states’ \cite{22, 23} with a tensor network representation \cite{24}. They are unique ground states of Hamiltonian of local commuting projectors with locality determined by the graph $G$. Here we show that these properties naturally carry over to the generalized graph states $|\psi_{G,H}\rangle$.

First of all, it is straightforward to show that $|\psi_{G,H}\rangle$ is a unique ground state of gapped Hamiltonian of commuting projectors. This is because that we know $|0\rangle^\otimes n$ is stabilized by $\{|0_i\rangle\langle 0_i|\}_{i=1}^n$, where $|0_i\rangle$ is $|0\rangle$ state of the $i$th qudit. Since $|\psi_{G,H}\rangle = U_{G,H} |0\rangle^\otimes n$, $|\psi_{G,H}\rangle$ is then stabilized by $\{U_{G,H} |0_i\rangle\langle 0_i| U_{G,H}^\dagger\}_{i=1}^n$. Therefore, $|\psi_{G,H}\rangle$ is the unique ground state of the gapped Hamiltonian

$$H = - \sum_{i=1}^n U_{G,H} |0_i\rangle\langle 0_i| U_{G,H}^\dagger,$$

where each term $U_{G,H} |0_i\rangle\langle 0_i| U_{G,H}^\dagger$ are mutually commuting. Furthermore, the locality of each $U_{G,H} |0_i\rangle\langle 0_i| U_{G,H}^\dagger$ is determined by the connectivity of the graph $G$, given the structure of $U_{G,H}$.

$|\psi_{G,H}\rangle$ has a representation as a tensor product state (also called the projective entanglement-pair states (PEPS)). To discuss this representation, we first choose the (un-normalized) ‘bond state’ between the sites $s, t$ to be

$$|\psi_{st}^{\text{bond}}\rangle = C_{st}^H \sum_{i_s, i_t} |i_s i_t\rangle,$$

where $i_s, i_t \in \{0, 1, \ldots, d-1\}$.

Consider a graph $G$. For each site $s \in V(G)$, denote $m(s)$ the degree of the vertex $s$ in $G$. Now consider a state $|\Psi_G\rangle$ which has $m(s)$ qudits on the site $s$, given by

$$|\Psi_G\rangle = \bigotimes_{st \in E(G)} |\psi_{st}^{\text{bond}}\rangle.$$

As an example, $|\Psi_G\rangle$ for a graph $G$ of four vertices and $E(G) = (12, 23, 34)$ is illustrated in Fig. 3.

![Fig. 3](image_url)

**FIG. 3.** $|\Psi_G\rangle$ for a graph $G$ of four vertices and $E(G) = (12, 23, 34)$. Each circle represent a site. Each black dot represent a qudit. And two black dots connected by a line represent a bond $|\psi_{st}^{\text{bond}}\rangle$.

**Proposition 7** $|\psi_{G,H}\rangle$ has the following representation

$$|\psi_{G,H}\rangle \propto \prod_{s \in V(G)} \left( \sum_{i_s=1}^d \frac{m(s)}{m(s)} |i_s i_s \ldots i_s\rangle \right) |\Psi_G\rangle.$$  

**Proof:** Notice that

$$|\psi_{G,H}\rangle \propto \prod_{st \in E(G)} C_{st}^H \otimes n |0\rangle^\otimes n$$

$$= \prod_{st \in E(G)} C_{st}^H \sum_{i_1 i_2 \ldots i_n} |i_1 i_2 \ldots i_n\rangle.$$  

(28)
On the other hand,

\[
\prod_{s \in V(G)} \left( \sum_{i_s=1}^{d} \left[ i_s \langle i_s i_s \ldots i_s | \right] \right) |\Psi_G\rangle
\]

\[
= \prod_{s \in V(G)} \left( \sum_{i_s=1}^{d} \left[ i_s \langle i_s i_s \ldots i_s | \right] \right) \left( \bigotimes_{rt \in E(G)} C_{rt}^{H} \sum_{i_r i_t} |i_r i_t\rangle \right)
\]

\[
= \prod_{st \in E(G)} C_{st}^{H} \sum_{i_1 i_2 \ldots i_n} |i_1 i_2 \ldots i_n\rangle. \tag{29}
\]

We remark that this tensor network representation may help to analyze what kind of generalized graph states may be resource states for measurement-based quantum computing \[22\].

**D. The tensor product structure**

It is easy to show that if \(H_1\) and \(H_2\) are Hadamard matrices, then \(H = H_1 \otimes H_2\) is also a Hadamard matrix. A natural question is then what is the relationship between the structure of \(|\psi_{G,H}\rangle\) and those of \(|\psi_{G,H_1}\rangle\) and \(|\psi_{G,H_2}\rangle\). This is given by the following proposition.

**Proposition 8** If \(H = H_1 \otimes H_2\), then \(\mathcal{W}_{G,H} = |\psi_{G,H_1}\rangle \otimes |\psi_{G,H_2}\rangle\) (up to qudit permutation).

**Proof:** Let the dimensions of \(H_1, H_2\) be \(d_1, d_2\), respectively. Since \(H_1\) and \(H_2\) are both Hadamard matrices, then \(H = H_1 \otimes H_2\) is also a Hadamard matrix of dimension \(d_1 d_2\). We identify the Hilbert space \(\mathbb{C}^{d_1 d_2}\) with \(\mathbb{C}^{d_1} \otimes \mathbb{C}^{d_2}\). Then \(H^{\otimes n} |0\rangle^{\otimes n}\) can be naturally interpreted as \((H_1 \otimes H_2)^{\otimes n} |0\rangle^{\otimes n}\). We then need to examine the generalized controlled-\(Z\), which reads

\[
C^H |i_1 i_2, j_1 j_2\rangle = H_{i_1 i_2, j_1 j_2} \sum_{i_1' j_1' j_2} |i_1' j_1 j_2\rangle = (H_1)_{i_1 j_1} \sum_{j_1' j_2} |i_1 j_1' j_2\rangle = (H_2)_{i_2 j_2} \sum_{i_1' j_1} |i_1' j_1 j_2\rangle = C^{H_1} |i_1 j_1\rangle \otimes C^{H_2} |i_2 j_2\rangle \tag{30}
\]

Then it is clear that under this identification of qudits, we have \(\mathcal{W}_{G,H} = |\psi_{G,H_1}\rangle \otimes |\psi_{G,H_2}\rangle\). \(\square\)

As an example, consider a triangle graph with the Hadamard matrix \(H'\) given by

\[
\begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}
\otimes
\begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}
\tag{31}
\]

The circuit for generating the corresponding generalized graph state \(\mathcal{W}_{\Delta, H'}\) is then given in Fig. 4 where \(H\) represents the single-qubit unitary operation \(\frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\), and the black dots connected by a line is just the usual controlled-\(Z\) gate of two qubits.

![FIG. 4. The circuit for generating the generalized graph state \(\mathcal{W}_{\Delta, H'}\) with the Hadamard matrix given in Eq. \(31\). \(|i_a\rangle |i_b\rangle\) for \(i = 1, 2, 3\) is the input \(\langle 0\rangle\) state for the \(i\)th qudit.](image-url)
IV. LOCAL EQUIVALENCE AND SYMMETRY

An important basic property of Hadamard matrices is their equivalence.

Definition 9 Two $d \times d$ Hadamard matrices $H_1$ and $H_2$ are equivalent if there exists two $d \times d$ permutation matrices $P_1, P_2$, and two diagonal matrices $D_1, D_2$, such that

$$H_1 = D_1 P_1 H_2 P_2 D_2.$$  \hfill (32)

The classification of complex Hadamard matrices for $d = 2, 3, 4, 5$ up to equivalence is given by the following theorem (see, e.g. [21]).

Theorem 10 For $d = 2, 3, 5$, any complex Hadamard matrix are equivalent to the discrete Fourier transform $F_d$. For $d = 4$, any complex Hadamard matrix is equivalent to $H_\alpha$ given by

$$H_\alpha = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & e^{i\alpha} & -e^{i\alpha} \\ 1 & -1 & -e^{i\alpha} & e^{i\alpha} \end{pmatrix},$$  \hfill (33)

where $\alpha \in \mathbb{R}$.

A. The local equivalence

We now study the relationship between the equivalence of Hadamard matrices and the LU equivalence of the corresponding generalized graph states. We first look at the relationship between the corresponding generalized controlled-$Z$ operations $C^H$. This will be given by the following two lemmas.

Lemma 11 For two equivalent $d \times d$ Hadamard matrices $H_2 = D_1 H_1 D_2$, where $D_1, D_2$ are $d \times d$ diagonal matrices,

$$C^{H_2} = (D_1 \otimes D_2) C^{H_1}. \hfill (34)$$

Proof: Assume $D_1 = \sum_{i=0}^{d-1} d_1, i |i\rangle \langle i|$ and $D_2 = \sum_{i=0}^{d-1} d_2, i |i\rangle \langle i|$. And denote $h_{ij}^{(1)}$ ($h_{ij}^{(2)}$) the matrix elements of $C^{H_1}$ ($C^{H_2}$). Then we have

$$C^{H_2} |ij\rangle = \sum_{i,j=0}^{d-1} h_{ij}^{(2)} |ij\rangle = \sum_{i,j=0}^{d-1} d_1, i d_2, j h_{ij}^{(1)} |ij\rangle = (D_1 \otimes D_2) C^{H_1} |ij\rangle. \hfill (35)$$

We illustrate this relationship between $C^{H_1}$ and $C^{H_2}$ in Fig. 5.

![Fig. 5](image_url)

FIG. 5. A graphical way for illustrating the relationship between $C^{H_1}$ and $C^{H_2}$ for $H_2 = D_1 H_1 D_2$. The left side represents $C^{H_1}$, and the right side represent $C^{H_2}$ in terms of $C^{H_1}$.

Lemma 12 For two equivalent $d \times d$ Hadamard matrices $H_2 = P_1 H_1 P_2^T$, where $P_1, P_2$ are $d \times d$ permutation matrices,

$$C^{H_2} = (P_1 \otimes P_2) C^{H_1} (P_1^T \otimes P_2^T). \hfill (36)$$
Proof: Denote \( i = P_1 i \) and \( j = P_2 j \). Notice that \( H_2 = \sum_{i,j=0}^{d-1} h_{i,j}(2) |i\rangle \langle j| = \sum_{i,j=0}^{d-1} h_{i,j}(1) |i\rangle \langle j| P_2 \), then \( h_{i,j}^{(2)} = h_{i,j}^{(1)} \).

Therefore we have

\[
C^{H_2} = \sum_{i,j=0}^{d-1} h_{i,j}^{(2)} |i\rangle \langle j| = \sum_{i,j=0}^{d-1} h_{i,j}^{(1)} |i\rangle \langle j|
\]

\[
= ((P_1 \otimes P_2)) \sum_{i,j=0}^{d-1} h_{i,j}^{(1)} \frac{1}{N} (P_1^T \otimes P_2^T) |i\rangle \langle j| (P_1 \otimes P_2) (P_1^T \otimes P_2^T)
\]

\[
= (P_1 \otimes P_2)C^{H_1} (P_1^T \otimes P_2^T). \quad \square
\]

We illustrate this relationship between \( C^{H_1} \) and \( C^{H_2} \) in Fig. 6.

**Fig. 6.** A graphical way for illustrating the relationship between \( C^{H_1} \) and \( C^{H_2} \) for \( H_2 = P_1 H_1 P_2 \). The left side represents \( C^{H_1} \), and the right side represent \( C^{H_2} \) in terms of \( C^{H_1} \).

To study the relationship between the LU equivalence of the corresponding generalized graph states \( |\psi_{G,H_1}\rangle \) and \( |\psi_{G,H_2}\rangle \), we will need the following concept of \( P \)-equivalent Hadamard matrices.

**Definition 13** Two Hadamard matrices \( H_1 \) and \( H_2 \) are called \( P \)-equivalent if there is a \( d \times d \) permutation \( P \) and two \( d \times d \) diagonal unitary matrices \( D_1 \) and \( D_2 \) such that

\[
H_1 = PD_1 H_2 D_2 P^T.
\]

(38)

Two \( P \)-equivalent Hadamard matrices are also equivalent, but two equivalent Hadamard matrices are in general not \( P \)-equivalent.

We remark that the latter is also true for two \( P \)-equivalent symmetric Hadamard matrices. That is, two equivalent symmetric Hadamard matrices may not be \( P \)-equivalent. A simple example is for \( d = 3 \), and choose

\[
H_1 =  \begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \\ 1 & \omega^2 & \omega \end{pmatrix} \quad \text{and} \quad H_2 =  \begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \\ 1 & \omega^2 & \omega \end{pmatrix} =  \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} \quad \text{for } \omega = e^{2i\pi/3}.
\]

(39)

where \( \omega = e^{2i\pi/3} \). And obviously \( H_1 \) and \( H_2 \) are not \( P \)-equivalent.

We now show that, two \( P \)-equivalent symmetric Hadamard matrices correspond to LU equivalent generalized graph states, for any graph \( G \).

**Theorem 14** If two symmetric Hadamard matrices \( H_1 \) and \( H_2 \) are \( P \)-equivalent, then \( |\psi_{G,H_1}\rangle \) and \( |\psi_{G,H_2}\rangle \) are LU equivalent.

Proof: Observe that for \( H_1 = PH_2 P^T \), the corresponding \( C^{H_1} \) and \( C^{H_2} \) satisfy \( C^{H_1} = (P \otimes P) C^{H_2} (P \otimes P)^T \), as given by Lemma 12. Now notice that \( PP^T = I \) and \( \sum_{i} |i\rangle \langle i|^\otimes n \) is invariant under the action of \( P \) on any qudit. Therefore, for Hadamard matrices \( H_1, H_2 \) with \( H_1 = PH_2 P^T \), \( |\psi_{G,H_1}\rangle \) and \( |\psi_{G,H_2}\rangle \) are LU equivalent.

For \( H_1 = D_1 H_2 D_2 \) the corresponding \( C^{H_1} \) and \( C^{H_2} \) satisfy \( C^{H_1} = (D_1 \otimes D_2) C^{H_2} \), as given by Lemma 11. Therefore, for Hadamard matrices \( H_1, H_2 \) with \( H_1 = D_1 H_2 D_2 \), \( |\psi_{G,H_1}\rangle \) and \( |\psi_{G,H_2}\rangle \) are LU equivalent □.

As an example, we illustrate the LU equivalence of two generalized graph states \( |\psi_{\Delta,H_1}\rangle \) and \( |\psi_{\Delta,H_2}\rangle \) for the triangle graph in Fig. 7 where the two Hadamard matrices \( H_1 \) and \( H_2 \) satisfy \( H_1 = PH_2 P^T \) for some permutation matrix \( P \).

A natural question is whether there exists a graph \( G \), such that \( |\psi_{G,H_1}\rangle \) and \( |\psi_{G,H_2}\rangle \) are not LU equivalent for two equivalent symmetric Hadamard matrices \( H_1 \) and \( H_2 \). This is indeed possible. First of all, we only need to discuss the case that two symmetric Hadamard matrices \( H_1 \) and \( H_2 \) are equivalent but not \( P \)-equivalent. Let us consider the \( d = 3 \) example given in Eq. 39a. Here \( H_1 \) is in fact the discrete Fourier transform for \( d = 3 \), so \( |\psi_{G,H_1}\rangle \) is the usual graph state. Notice that in fact \( C^{H_2} = (C^{H_1})^2 \), consequently \( |\psi_{G,H_2}\rangle \) is a ‘weighted graph’ state with edge weight 2 for each edge. And it is known that the weighted graph states are in general not LU equivalent to the ‘unweighted graph’ states 28.
Since both $H_2 = P H_1 P^T$ for some permutation matrix $P$. Two black diamonds connected by a line represents $C^{H_1}$. This circuit generates the state $|\psi_{\triangle, H_2}\rangle$, which is given by Lemmas 11 and 12 from the circuit generating of $|\psi_{\triangle, H_1}\rangle$. Notice that each $PP^T = I$, so they do cancel. And $PH_1|0\rangle = DH_1|0\rangle$ for some diagonal matrix $D$, which commutes with all the diagonal $C^{H_1}$s. This then shows that $|\psi_{\triangle, H_2}\rangle = (P^T D \otimes I)|\psi_{\triangle, H_1}\rangle$.

Although in general equivalent Hadamard matrices $H_1$ and $H_2$ may correspond to LU inequivalent generalized graph states $|\psi_{G, H_1}\rangle$ and $|\psi_{G, H_2}\rangle$, one would ask for what kind of graphs that $|\psi_{G, H_1}\rangle$ and $|\psi_{G, H_2}\rangle$ are LU equivalent. We will show that it is the case if $G$ is a bipartite graph. That is, the vertex set $V(G)$ of $G$ can be divided into two disjoint sets $V_1$ and $V_2$ such that there does not exists any edge $ab \in E(G)$ with $a \in V_1$ and $b \in V_2$, i.e. every edge of $G$ connects on vertex in $V_1$ to another one in $V_2$.

**Theorem 15** If $G$ is a bipartite graph, then $|\psi_{G, H_1}\rangle$ and $|\psi_{G, H_2}\rangle$ are LU equivalent for two equivalent symmetric Hadamard matrices $H_1$ and $H_2$.

**Proof**: According to Lemma 11 we only need to deal with $H_2 = P_1 H_1 P_2^T$, where $P_1$ and $P_2$ are two permutation matrices. Since both $H_1$ and $H_2$ are symmetric, we also have $H_2 = P_2 H_1 P_1^T$. According to Lemma 12 we then have

$$C^{H_2} = (P_1 \otimes P_2) C^{H_1} (P_1^T \otimes P_2^T) = (P_2 \otimes P_1) C^{H_1} (P_2^T \otimes P_1^T).$$

(40)

This means that for implementing each $C^{H_2}$ in terms of $C^{H_1}$ and single-qudit permutation operations $P_1/P_1^T$ and $P_2/P_2^T$, we can choose which of the two qudits (that $C^{H_2}$ is acting on) to apply $P_1/P_1^T$ or $(P_2/P_2^T)$ on. Notice that for bipartite graph $G$ with $V(G) = V_1 \cup V_2$, we can than apply $P_1/P_1^T$s on vertices in $V_1$, and apply $P_2/P_2^T$s on vertices in $V_2$. Then the argument of 14 will follow for this case, where $P_1 P_1^T = P_2 P_2^T = I \square$.

As an example, we consider a bipartite graph $G$ of $n = 4$, as shown in Fig. 8.

![Fig. 7. The LU equivalence of two generalized graph states $|\psi_{\triangle, H_1}\rangle$ and $|\psi_{\triangle, H_2}\rangle$. The two Hadamard matrices $H_1$ and $H_2$ satisfy $H_2 = P H_1 P^T$ for some permutation matrix $P$. Two black diamonds connected by a line represents $C^{H_1}$. This circuit generates the state $|\psi_{\triangle, H_2}\rangle$, which is given by Lemmas 11 and 12 from the circuit generating of $|\psi_{\triangle, H_1}\rangle$. Notice that each $PP^T = I$, so they do cancel. And $PH_1|0\rangle = DH_1|0\rangle$ for some diagonal matrix $D$, which commutes with all the diagonal $C^{H_1}$s. This then shows that $|\psi_{\triangle, H_2}\rangle = (P^T D \otimes I)|\psi_{\triangle, H_1}\rangle$.](image)

![Fig. 8. An $n = 4$ bipartite graph $G$, with the vertices set $V(G) = V_1 \cup V_2$, where $V_1 = \{1, 3\}$ and $V_2 = \{2, 4\}$.](image)

Now consider two Hadamard matrices $H_2 = P_1 H_1 P_2^T$. The LU equivalence of the corresponding generalized graph states $|\psi_{G, H_1}\rangle$ and $|\psi_{G, H_2}\rangle$ is then shown in Fig. 9.

![Fig. 9.](image)

**B. Local symmetries**

Due to Theorem 13 we will assume the Hadamard matrix $H$ has entries 1 in the first row and first column in the following discussion.

**Definition 16** For a symmetric Hadamard matrix $H$, if there is a $d \times d$ permutation $P$ and a $d \times d$ diagonal unitary $D$ such that

$$PHD = H,$$

(41)

then the pair $(P, D)$ is called a $S$-symmetry of $H$. 
Proposition 17 Let $G$ be any graph with $n$ vertices, and let $H$ be a $d \times d$ Hadamard. For any $S$-symmetry, $(P, D)$, the graph state $|\psi_{G;H}\rangle$ is stabilized by $P_a \prod_{ab \in E(G)} D_b$ for any $a \in V(G)$.

Proof: For any $a \in V(G)$, let $E_a = \{ij \in E(G)|i = a \text{ or } j = a\}$, $A_a = \prod_{ij \in E_a} C_{ij}^H$, and let $B_a = \prod_{ij \in E(G) \setminus E_a} C_{ij}^H$.

Then we have $|\psi_{G;H}\rangle = d^{-\frac{n}{2}} B_a A_a H^{\otimes n} |0\rangle^{\otimes n}$.

By Lemma 11 and Lemma 12 $C^H = C^{PHD} = (P \otimes D)C^H (P^T \otimes I)$. Then

$$A_a = \prod_{ab \in E_a} C^{PHD}_{ab} = P_a( \prod_{ab \in E_a} D_b)( \prod_{ab \in E_a} C_{ab}^H) P_a^T = P_a( \prod_{ab \in E_a} D_b) A_a P_a^T. \quad (42)$$

Note that $P_a^T H_a |0\rangle = H_a |0\rangle$, and $D_b$ and $P_a$ both commute with $B_a$. Therefore, we have

$$|\psi_{G;H}\rangle = d^{-\frac{n}{2}} B_a A_a H^{\otimes n} |0\rangle^{\otimes n}$$
$$= d^{-\frac{n}{2}} B_a P_a( \prod_{ab \in E_a} D_b) A_a P_a^T H^{\otimes n} |0\rangle^{\otimes n}$$
$$= d^{-\frac{n}{2}} P_a( \prod_{ab \in E_a} D_b) A_a H^{\otimes n} |0\rangle^{\otimes n}$$
$$= P_a \prod_{ab \in E_a} D_b |\psi_{G;H}\rangle. \quad \Box \quad (43)$$

For example, if we take $H$ to be the discrete Fourier transform $F_d$, and let $P, D$ be the pauli operators $X_d^\dagger, Z_d$, respectively. Then $X_d^\dagger F_d Z_d = F_d$, and the local symmetry is given by $(X_d^\dagger)_{a \in E(G)} \prod_{b \in E(G)} (Z_d)_{b}$, which is consistent with Eq. (7), and we recover Theorem 1 in [13].

Another example is the family of Hadamard matrices $H_\alpha$ in dimension 4 given in Equation (33). Let $P, D$ be given as follows.

$$P = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{pmatrix}, \quad D = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}. \quad (44)$$

Then $P H_\alpha D = H_\alpha$. Notice that $P (= P^\dagger)$ and $D$ commute, so they cannot be Pauli $X_d$ and $Z_d$ operators on the same qudit. In this sense we provide a natural generalization of the Pauli $(X_d, Z_d)$ pairs.

V. The Triangle Graph

As a concrete example to discuss the different between a generalized graph state and a usual graph state, we use the triangle graph. As given by Theorem [14] we only need to discuss the case where the Hadamard matrix $H$ is ‘dephased’, that is, the matrix elements of the first row/column are all 1s. This can be always achieved by $D_1 H D_2$, i.e. multiplying diagonal matrices from left and right, and the resulted graph states will be just LU equivalent.
The triangle $\triangle$ has the edge set $E(G) = \{(12), (23), (13)\}$, as given by Figure 1(c). This gives

$$|\psi_{\triangle,H}\rangle = \frac{1}{d^{3/2}} C_{12}^{H} C_{23}^{H} C_{13}^{H} \sum_{ijk} |ijk\rangle = \frac{1}{d^{3/2}} \sum_{ijk} h_{ijk} h_{jk} h_{ik} |ijk\rangle. \quad (45)$$

The structure of $|\psi_{\triangle,H}\rangle$ is less obvious. That is, we would like to know whether these $|\psi_{\triangle,H}\rangle$ may be LU equivalent to each other, for different choices of $H$. We start from the following lemma.

**Lemma 18** If $H$ is the discrete Fourier transform $F_{d}$, then $|\psi_{\triangle,H}\rangle$ is LU equivalent to the GHZ state $|\text{GHZ}_{3,d}\rangle$.

**Proof:** We use stabilizer formalism. Consider the generalized Pauli matrices $X_{d}, Z_{d}$ satisfying

$$X_{d}Z_{d} = g_{d}Z_{d}X_{d}, \quad (46)$$

where $g_{d} = \exp(\pm i\pi/d)$. Then $|\psi_{\triangle,H}\rangle$ is stabilized by the stabilizer group generated by $g_{1}, g_{2}, g_{3}$, given by

$$g_{1} = X_{d}^{\dagger} \otimes Z_{d} \otimes Z_{d},$$
$$g_{2} = Z_{d} \otimes X_{d}^{\dagger} \otimes Z_{d},$$
$$g_{3} = Z_{d} \otimes Z_{d} \otimes X_{d}^{\dagger}. \quad (47)$$

We now choose another set of generators

$$g_{1}' = g_{1} = X_{d}^{\dagger} \otimes Z_{d} \otimes Z_{d},$$
$$g_{2}' = (g_{1}g_{2}) = (X_{d}Z_{d}) \otimes (Z_{d}X_{d}^{\dagger}) \otimes I,$$
$$g_{3}' = g_{2}' g_{3} = I \otimes (X_{d}Z_{d}) \otimes (Z_{d}X_{d}^{\dagger}). \quad (48)$$

Notice that

$$(X_{d}Z_{d})Z_{d} = g_{d}Z_{d}(X_{d}Z_{d}), \quad (49)$$

there exists a local Clifford (LC) transformation which maps

$$(X_{d}Z_{d}) \rightarrow X_{d}, \ Z_{d} \rightarrow Z_{d}. \quad (50)$$

Applying this transform on all of the three qudits maps

$$g_{1}' \rightarrow g_{1} = Z_{d}X_{d}^{\dagger} \otimes Z_{d} \otimes Z_{d},$$
$$g_{2}' \rightarrow g_{2}' = X_{d} \otimes X_{d}^{\dagger} \otimes I,$$
$$g_{3}' \rightarrow g_{2}' g_{3} = I \otimes X_{d} \otimes X_{d}^{\dagger}. \quad (51)$$

Furthermore, since

$$X_{d}(Z_{d}X_{d}^{\dagger}) = g_{d}(Z_{d}X_{d}^{\dagger})X_{d}, \quad (52)$$

there exists an LC transformation which maps

$$X_{d} \rightarrow X_{d}, \ Z_{d}X_{d}^{\dagger} \rightarrow Z_{d}. \quad (53)$$

Applying this transform on the first qudit maps

$$g_{1}' \rightarrow g_{1} = Z_{d} \otimes Z_{d} \otimes Z_{d},$$
$$g_{2}' \rightarrow g_{2}' = X_{d} \otimes X_{d}^{\dagger} \otimes I,$$
$$g_{3}' \rightarrow g_{2}' g_{3} = I \otimes X_{d} \otimes X_{d}^{\dagger}. \quad (54)$$

which is LU equivalent to the GHZ state $|\text{GHZ}_{3,d}\rangle$.

When $H$ is not the discrete Fourier transform $F_{d}$, $|\psi_{\triangle,H}\rangle$ may still be LU equivalent to $|\text{GHZ}_{3,d}\rangle$. In fact, this is true for all $d = 2, 3, 4, 5$, which can be shown based on the classification of complex Hadamard matrices in these dimensions, as given by the following theorem.
Theorem 19 For $d = 2, 3, 4, 5$ $|\psi_{\Delta,H}\rangle$ is LU equivalent to the GHZ state $|\text{GHZ}_{3,d}\rangle$ for any $H$.

Proof: We first prove this theorem up to equivalence of Hadamard matrices. For $d = 2, 3, 5$, any complex Hadamard matrix are equivalent to the discrete Fourier transform $\mathcal{F}_d$, which is then covered by Lemma 18. And for $d = 4$ and $H_\alpha$, $|\psi_{\Delta,H_\alpha}\rangle$ is a GHZ state as follows,

$$
|\psi_{\Delta,H_\alpha}\rangle = (|0\rangle + |1\rangle) e^{i\alpha/2}|0\rangle e^{i\alpha/2}|3\rangle) \otimes 3
+ (|0\rangle + |1\rangle - e^{i\alpha/2}|0\rangle + e^{i\alpha/2}|3\rangle) \otimes 3
+ e^{-3i\alpha/2}(|-0\rangle + |1\rangle + e^{3i\alpha/2}|2\rangle + e^{3i\alpha/2}|3\rangle) \otimes 3
+ (|0\rangle - |1\rangle + e^{3i\alpha/2}|2\rangle + e^{3i\alpha/2}|3\rangle) \otimes 3.
$$

Now for $d = 2, 3, 5$, we need to deal with the cases where $PD\mathcal{F}_d$ are still symmetric, for some permutation matrix $P$ and some diagonal matrix $D$.

For $d = 2$, such $P$ and $D$ have to be identity.

For $d = 3$, such $P, D$ can be identity or $PD\mathcal{F}_3 = \mathcal{F}_3^*$, the later one of course generates a GHZ state for triangle graph.

For $d = 5$, such $P, D$ has to satisfy that

$$
PD\mathcal{F}_5 = \mathcal{F}_5(w^k) = (w^{ijk})_{5\times 5}, 1 \leq k \leq 4
$$

employing the above lemma, such Hadamard matrix generates a GHZ state for triangle graph by using $w^k$ instead of $w = e^{2\pi i/5}$.

For $d = 4$, we also need to deal with the cases where $PDH_\alpha$ are still symmetric, for some permutation matrix $P$ and some diagonal matrix $D$.

Case 1, $e^{i\alpha} \neq \pm 1$, such $P, D$ has to satisfy that

$$
PDH_\alpha = \begin{pmatrix}
1 & 1 & 1 & 1 \\
1 & 1 & -1 & -1 \\
1 & -1 & e^{i\alpha} & -e^{i\alpha} \\
1 & -1 & -e^{i\alpha} & e^{i\alpha}
\end{pmatrix}
$$

such Hadamard matrix generates a GHZ state for triangle graph by using $e^{i\alpha}$ instead of $-e^{i\alpha}$.

Case 2, $e^{i\alpha} = \pm 1$, such $P, D$ has to satisfy that $PDH_\alpha$ equals on of the following matrices

$$
\begin{pmatrix}
1 & 1 & 1 & 1 \\
1 & 1 & -1 & -1 \\
1 & -1 & 1 & -1 \\
1 & -1 & -1 & 1
\end{pmatrix},
$$

$$
\begin{pmatrix}
1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 \\
1 & -1 & -1 & 1 \\
1 & -1 & 1 & -1
\end{pmatrix},
$$

$$
\begin{pmatrix}
1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 \\
1 & 1 & -1 & 1 \\
1 & -1 & -1 & 1
\end{pmatrix}.
$$

The fact that $\tilde{H}_a (\tilde{H}_b)$ corresponds to a generalized graph states $|\psi_{\Delta,H_a}\rangle (|\psi_{\Delta,H_b}\rangle)$ that is LU equivalent to $|\text{GHZ}_{3,d}\rangle$ simply follows from the previous argument for general $\alpha$ for $H_a$.

The third matrix $\tilde{H}_c = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \otimes \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$, so it corresponds to a generalized graph state $|\psi_{\Delta,\tilde{H}_c}\rangle$ that is LU equivalent to $|\text{GHZ}_{3,d}\rangle$, using Proposition 8.

For the last matrix $\tilde{H}_d$, we notice that

$$
\tilde{H}_d = \text{CNOT}\tilde{H}_c\text{CNOT},
$$

where

$$
\text{CNOT} = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0
\end{pmatrix}
$$

is just the usual controlled-NOT operation on two-qubits. Then it directly follows from Theorem 14 that the corresponding generalized graph state $|\psi_{\Delta,\tilde{H}_d}\rangle$ is LU equivalent to $|\text{GHZ}_{3,d}\rangle$, for the triangle graph. We give the circuit explicitly in Fig. 14 □.

The case for $d \geq 6$ is much more complicated, as we know there is no classification of Hadamard matrices in these higher dimensions. However, we can indeed show that for $d = 6$, some of the choices of $H$ give the states $|\psi_{\Delta,H}\rangle$ which are not GHZ states. This shows that even for a small $n = 3$, the generalized graph states $|\psi_{\Delta,H}\rangle$ may not be local unitary equivalent to a usual graph state.
In general, $|\psi_{\Delta,H}\rangle$ may not be LU equivalent to $|\text{GHZ}_{3,d}\rangle$.

**Proof:** We use some known results based on invariant theory. We consider the degree 6 invariants as discussed in [27]. The LU invariant we compute is

$$I_6 = \text{Tr}(\rho_{12})^3,$$  \hspace{1cm} \text{(60)}

where $\rho_{12}$ is the reduced density matrix (RDM) of the 1, 2 qudits, and $T_1$ is the partial transpose on qudit 1.

For the $|\text{GHZ}_{3,6}\rangle$, we have

$$I_6(|\text{GHZ}_{3,6}\rangle) = 0.0278.$$  \hspace{1cm} \text{(61)}

Now we consider the generalized graph state $|\psi_{\Delta,H}\rangle$ with

$$H = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & i & -i & -i & i \\ 1 & i & -1 & i & -i & -i \\ 1 & -i & i & -1 & i & -i \\ 1 & -i & -i & i & -1 & i \\ 1 & i & -i & -i & i & -1 \end{pmatrix}.$$  \hspace{1cm} \text{(62)}

Direct computation gives

$$I_6(|\psi_{\Delta,H}\rangle) = 0.0150.$$  \hspace{1cm} \text{(63)}

This means that $|\psi_{\Delta,H}\rangle$ is not LU equivalent to $|\text{GHZ}_{3,6}\rangle$. □

We remark that alternatively, we can observe the following: a) two tripartite states are LU equivalence iff their 2-RDMs are LU equivalent; b) two bipartite mixed states $\rho_{AB}$ and $\sigma_{AB}$ are LU equivalent iff their corresponding quantum operations $\mathcal{E}$ and $\mathcal{F}$ are unitarily equivalent, $\mathcal{E} = U \circ \mathcal{F} \circ V$ for some unitary operations $U, V$, where $\rho_{AB}$ and $\sigma_{AB}$ are the Choi matrices of $\mathcal{E}$ and $\mathcal{F}$. We know that the quantum operation corresponding to $|\text{GHZ}_{n,d}\rangle$ is $\mathcal{E} = \sum_{i=0}^{n-1} E_i \cdot E_i^\dagger$ with $E_i = |i\rangle\langle i|$. And for the matrix $H$ we choose, the corresponding quantum operation is $\mathcal{F} = \sum_{i=0}^{3} F_i \cdot F_i^\dagger$ with $F_i = \Gamma_1 H \Gamma_1$. Notice that if $|\text{GHZ}_{n,d}\rangle$ is LU equivalent to $|\psi_{\Delta,H}\rangle$, then $\mathcal{E}$ and $\mathcal{F}$ are unitarily equivalent. There then exists two unitary operations $U, V$ such that $UFV$ are all diagonal. As a direct consequence, $F_i^\dagger F_j$ are all commute. Now for the Hadamard matrix $H$ as given in Eq. (62), since $F_i^\dagger F_j$ are not all commute, we can conclude that $|\psi_{\Delta,H}\rangle$ is not LU equivalent to $|\text{GHZ}_{3,d}\rangle$.

All these methods discussed above to prove Proposition 20 can be directly used to test the LU properties of other generalized graph states, $|\psi_{G,H}\rangle$ for different choices of the Hadamard matrix $H$ and different graphs $G$. 

FIG. 10. $|i_a\rangle\langle i_b|$ for $i = 1, 2, 3$ is the input $|0\rangle$ state for the $i$th qudit. $H$ is the single-qubit Hadamard transform (multiply by a factor of $1/\sqrt{2}$). The two Hadamard matrices $\tilde{H}_c$ and $\tilde{H}_d$ satisfy $\tilde{H}_d = \text{CNOT}\tilde{H}_c\text{CNOT}$. Two black dots connected by a line represents the usual controlled-Z operation. One black dot connected with an $\oplus$ by a line represents the usual controlled-NOT operation, with the black dot denotes the controlled qubit. This circuit generates the state $|\psi_{\Delta,B_a}\rangle$, which is given by Lemmas 11 and 12 from the circuit generating of $|\psi_{\Delta,B_a}\rangle$. Notice that CNOT$^4 = I$, so two CNOTs do cancel. And CNOT$|0\rangle\langle 0|_a = |0\rangle\langle 0|_a, |0\rangle\langle 0|_a$. This then shows that $|\psi_{\Delta,B_a}\rangle = (\text{CNOT})^\oplus_3 |\psi_{\Delta,B_a}\rangle$. 

Proposition 20
VI. GENERALIZED GRAPH CODES

Eq. (16) in fact defines an encoding circuit. That is, instead of starting from the state $|0\rangle^\otimes n$, one can start from any computational basis state. Note that for any $|i\rangle$, we have

$$H|i\rangle = \Gamma_i H|0\rangle,$$

(64)

where $\Gamma_i$ is the diagonal matrix with the diagonal elements the $i$th row/column of $H$. And here we again assume that the elements of the first row/column of $H$ are all 1s.

Therefore, for an $n$-qubit computational basis state $|i_1i_2\ldots i_n\rangle$, we have

$$U_{G,H}|i_1i_2\ldots i_n\rangle = \frac{1}{d^{n/2}} \prod_{ij \in E(G)} C_{ij}^H|H^\otimes n|i_1i_2\ldots i_n\rangle = \bigotimes_{k=1}^n \Gamma_{i_k} |\psi_{G,H}\rangle,$$

(65)

which is LU equivalent to $|\psi_{G,H}\rangle$ up to some diagonal local unitary determined by the columns of $H$.

Eq. (65) shows that the computational basis states $|i_1i_2\ldots i_n\rangle$ are mapped to orthogonal generalized graph states (corresponding to the same graph), by the encoding circuit $U_{G,H}$ as given in Eq. (16). For an $n$-dit classical string $c = c_1c_2\ldots c_n$, denote the corresponding quantum computational basis state by $|c\rangle$, and $U_{G,H}|c\rangle = |\psi_{G,H}(c)\rangle$. Then for any $n$-dit classical code $C$, the encoding circuit $U_{G,H}$ gives a quantum code $Q_C$, whose dimension is the same as the cardinality of $C$, and spanned by an orthonormal basis $|\psi_{G,H}(c)\rangle$ for $c \in C$. In this sense, we can say that the ‘codewords’ of $Q_C$ are generalized graph states. This then gives a direct generalization of the graph codes [5], when $C$ is a linear code. More generally, it gives a direct generalization of the codeword stabilized (CWS) codes [6, 28–30] (where $H$ is the Fourier transform $F_n$).

When the dimension of $Q_C$ is 1, it is a generalized graph state, and we already know from Proposition 20 that it is not LU equivalent to a CWS code. Here we give an example of $Q_c$ with dimension $d = 4$ that is not LU equivalent to a CWS code of the same classical code $C$ and the same graph $G$.

Consider the triangle graph $\triangle$ and the $4 \times 4$ Hadamard matrix $H_\alpha$ as given in Eq. (33). Now choose the classical code as the linear code

$$C = \{000, 111, 222, 333\},$$

(66)

then the corresponding quantum code $Q_C$ has length 3 and encodes an 1. And one can check that $Q_C$ has distance 2, so using the coding theory notation, $Q_C$ is an $[[3, 1, 2]]_4$ code.

By calculating the weight enumerators of $Q_C$, we know that $Q_C$ is not LU equivalent to a CWS code for some $\alpha$. For instance, $\alpha = \pi/5$. Since $C$ is linear, the corresponding CWS code is in fact additive. This shows that $Q_C$ is not an additive code for some $\alpha$. This provides a systematic method to construct non-additive quantum codes from linear classical code.

The error-correcting property of these codes would depend on both the structure of the graph $G$, and that of the Hadamard matrix $H$. For a single-qudit error $E$, one can equivalently analyze the effect of $U_{G,H}EU_{G,H}^\dagger$ on the quantum code spanned by the basis states $|c\rangle$ for $c \in C$. For example, consider the triangle graph $\triangle$ with the encoding circuit $U_{G,H}$ as given in Fig. 11. And the circuit of $U_{G,H}EU_{G,H}^\dagger$ is illustrated in Fig. 11 (for the error $E$ acting on the first qudit).

![Fig. 11. The effect of a single qudit error $E$ after decoding. Here the bar on top of each $C_{ij}^H$ means $(C_{ij}^H)^\dagger$, i.e. its hermitian conjugate.](image)

If $E$ is diagonal, then effectively on the code spanned by $|c\rangle$, we still have a single qubit error, given by $HEH^\dagger$. And, if $E$ corresponds to a generalized Pauli $X$ operator as discussed in Sec. IVB, then $HEH^\dagger$ remains to be a tensor product of local operators, whose effect on computational basis states is relatively easy to analyze. For a general $E$, the structure of $HEH^\dagger$ may be complicated. We will leave the analysis of the effect of errors for these generalized graph/CWS codes for future work.
