Determinants of Credit and Financing Risk: Evidence of Dual Banking System in Indonesia

Raditya Sukmana

Abstract. Given the fact that banking is the backbone of the Indonesian economy with a dual banking system. This paper seeks determinants of default rate in Indonesia. Various techniques of econometric tools such as unit root, co-integration test and Impulse Response Function (IRF) utilized. Bank capital has similar influence on the own credit or financing risks. Overall economic performance has a different result to the risk. Among the recommendations are for the government to maintain economic performance to keep default rate as low as possible. Financing Deposit Ratio-based Reserve Requirement policy (which is adopted only in Indonesia) imposed by the central bank seems to be effective in developing the real sector and should adopt in conventional banks.

Keywords: credit risk, financing risk, Islamic banking, conventional banking.

Abstrak. Mengingat fakta bahwa perbankan merupakan tulang punggung perekonomian Indonesia dengan sistem dual banking. Makalah ini mencari faktor penentu tingkat pembiayaan bermasalah di Indonesia. Berbagai teknik alat ekonometrik seperti uji akar unit, uji kointegrasi dan fungsi IRF digunakan. Modal bank memiliki pengaruh yang sama terhadap risiko kredit atau pembiayaan. Secara keseluruhan kinerja ekonomi memiliki hasil yang berbeda terhadap risikonya. Di antara rekomendasi tersebut adalah agar pemerintah dapat mempertahankan kinerja ekonomi agar tingkat suku bunga tetap serendah mungkin. Kebijakan Kebijakan rasio pembiayaan-deposito berbasis kewajiban cadangan (hal ini diadopsi di Indonesia) yang dipaksakan oleh bank sentral tampaknya efektif dalam mengembangkan sektor riil dan harus diadopsi di bank konvensional.

Kata kunci: risiko kredit, risiko pembiayaan, perbankan syariah, perbankan konvensional.

Introduction

Following subprime mortgage crisis in 2008 that brought a slight decrease of 4.6% in Indonesian economic growth, it bounced back to more than 6% in the subsequent years. Based on the data from the central bank, in 2011, the economic growth reached to 6.49% that was the highest since the subprime crisis (SPI October BI, 2014). Positive economic performance of Indonesia could not have achieved if it was not supported by the banking industry as asserted by Goeltom (2007). This industry was vital in assisting Indonesian economic activities. For such a long time, banking industry comprised only conventional banks until the introduction of first Islamic bank namely Bank of Muamalat Indonesia in 1992. The founding of this bank paved the way for other Islamic banks such as Bank of Sharia Mandiri that established in 1998. In term of its asset, in 2000, amounts reached IDR 1,790,168 million, accounting for only 0.17% of total banking assets. 2004 marked the year in which the proportion of Islamic banking assets surpassed 1% (Islamic Banking Statistics, August 2004). In 2013, the assets, financing, and deposits reached IDR 242,276,169 million, IDR 184,122,000 million, and IDR 183,534,056 million, respectively.

Given the significant role of the banking industry in the Indonesian economy, it is highly important to ensure the successful performance of Islamic banks. Such success reflected in various banking indicators of which Non-performing loan (NPL) is one of the important variables. NPL accounts for how much the default of the banks. In the other word, NPL indicates whether the borrowers can pay back the loans. The current study will focus largely on the issue of NPLs.

In essence, since NPLs are a significant indicator of banking performance, it is vital to determine the factors influencing NPLs. The term “NPL” is used in conventional banks to refer to defaulted loans. Non-performing financing (NPF) is used in Islamic Banks to refer defaulted financing. The term “loan” would refer to the use of interest, which is prohibited in Islam, whereas “financing” adopts the term “margin” or “rental fees,” depending on the involved contract. As the Islamic banking industry is gaining prominence in the country, this study looks at both indicators (NPF and NPL).

Table 1. Default Rate (NPF and NPL) in Indonesia

|       | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 |
|-------|------|------|------|------|------|------|
| NPF (%) |      |      |      |      |      |      |
| SME   | 4.08 | 3.64 | 4.50 | 3.47 | 2.98 | 2.27 |
| NonSME| 3.97 | 4.71 | 2.44 | 1.52 | 1.45 | 2.13 |
| NPL (%)|      |      |      |      |      |      |
| SME   | 3.50 | 3.27 | 3.08 | 2.60 | 2.27 | 2.79 |
| NonSME| 4.64 | 3.14 | 3.54 | 2.52 | 2.06 | 1.20 |

2. The Islamic Banking Statistics, Bank of Indonesia (rearranged)
From the Table 1, we can infer that NPF in the case of Small Medium Enterprise (SME) is higher than that of the Non-SME. For example, in 2007 NPF for SME and non-SME are 4.08 and 3.97. The other years such as 2008 to 2012 NPFs for SME are almost consistently higher than that of non-SME except in 2008 whereby NPF for non-SME, 4.71 is higher than that of SME which is 3.64. Quite similarly is the performance of NPL both for SME and non-SME. NPL for SME is higher than that of non-SME such as in the year 2008, 2010, 2011 and 2012. Only two years, which are, 2007 and 2009 where NPLs for SME is lower than that of non-SME.

The possible reason of why NPF and NPL both for SME are higher than that of non-SME is because SME may not have a proper and accurate financial record administration. This phenomenon may create asymmetric information, which eventually leads to the default payment by the SME. Meanwhile non-SME tends to have a comprehensive financial reporting system, and even more, it audited by the external party. Thus, less possibility of the default payment as compared as to that for SME.

As asserted by Goeltom (2007) that banking is the backbone of the Indonesian economy, hence ensuring the low level of NPF or NPL is very important. To do so, it is of substance to look into the determinant of NPF and NPL. The identification of the determinants is crucial for the monetary authority to issue necessary policies. Many studies about these issues have been done, including work by Boudriga et al. (2009a); Keeton (1999); Berger and de Young (1997); Godlewski (2005). The loan, bank size, and capital adequacy are the factors used to determine NPF. Other macro variables such as gross domestic product (GDP) and inflation are also adopted. The relationship between those variables and NPL/NPF will address in the literature section. The sequence of the paper is as follows: after the introduction, it followed by a review of the literature review and then a description of the data, model, and method used for the study. After that, results and analysis given followed by the conclusion.

Literature Review

This chapter discusses the findings for the various determinants of NPL and NPF. The discussion would base on the determinants and the NPL/NPF. Extensive studies have done on this issue. The study by Boudriga et al. (2009b) on MENA region resulted from a negative relationship between credit growth and NPL. However, Keeton (1999) found that credit growth has a positive relationship with NPLs. He argued that high increase in loans comes from lower standard in the loan procedure. For example, business proposals that may reject
under high standard loan procedures can approve for financing under the lesser standards.

The relationship between loan growth and NPLs also examine by Kwan and Eisenbeis (1997). They found that growth in loans negatively associated with bad loans but that the square of the one-year total loan growth rate positively correlated with bad loans. The authors concluded that the relationship between loan growth and bad loans is U-shaped. This result means that when loan growth is low, it has an adverse effect on NPLs. When the loan growth increases, it diminishes NPLs and when there exists high loan growth, the amount of bad loans increases.

In other words, They argue that sustainable loan growth as it is characterized by a low to moderate loan growth rate is a reflection of the good quality of management which eventually results from a smaller number of bad loans. However, if the loan growth is excessive in which can achieve by adopting lesser quality of lending standard, it leads to the higher number of bad loans. If the loan growth returns to low to medium, then bad loans will be reduced. This fact is what they mean by U-Shaped

Big banks certainly have more complex rules and regulations. The ability of big banks to provide a large loan to a single company necessitates a more substantial amount of scrutiny and documentation, which aims to mitigate the loan risk. In essence, their standard operating procedure (SOP) for lending is more stringent than that of the small banks. Conversely, for a small bank, the money provided in a loan is relatively less than that of big banks. The required documentation and standard operating procedure will also be more straightforward. This fact exposes smaller banks to more credit risk due to asymmetric information. Thus, the larger the size of the bank, the lower the amount of NPLs. Further study on this issue can found in the work of Shrieves (1992); Nicolo (2000); Godlewski (2005).

For a bank that is about to become insolvent, recapitalization is essential to avoid further deterioration. The standard of capital adequacy ratio (CAR) used as its indicators is 8%. Thus, when a bank has CAR of less than 8%, it can then be considered that the bank is unable to face the risk of given productive assets. Conversely, a bank with a CAR, which is much higher than 8%, the Bank has more ability to face the risk. For a bank having less than the specified CAR, the central bank will request the bank to add more capital relative to the given risk of the asset on the bank’s balance sheet. Another alternative is for the bank to reduce the weighted risk asset to maintain the CAR. Boudriga et al. (2009a) suggest that regulatory capital can serve as an indicator of the financial risk exposure of the whole system.
The relationship between CAR and NPL varies. The negative association means that increase in CAR will decrease NPL and this can be seen in the study by Boudriga, et al. (2009a), Berger and DeYoung (1997), and Godleswki (2005). Increase in CAR means that there is a higher source of loan and eventually higher credit will absorb current NPL. This phenomenon is the argument of the negative relationship between CAR and NPL. However, there is also study that shows otherwise which means CAR and NPL has a positive relationship that means when CAR increase, NPL is also increased. This fact can be seeing in the study by Boudriga et al (2009b). They argue that increase in CAR leads the management to take higher credit risk that eventually creates higher NPL. Based on the obtained previous study, despite many of them has a negative relationship between CAR and NPL, there is also study in which the relationship is positive. Hence, for the conclusion, there is no consensus on the relationship between the two as it argued by Boudriga et al (2009b).

Many studies have conducted about the relationship between GDP and NPL. Shu (2002), Festic and Beko (2008), Zeman and Jurca (2008), Farhan, et al. (2012) are some of the studies focusing on those variables. The secondary data of NPL used from the first three studies above are not the individual NPL of a bank; instead each of those studies utilizes the aggregate NPL within the respective countries. Data frequent adopted varies between quarterly and annually except for the Farhan et al (2012) which they attempt to obtain the primary data. To do so, they distribute the questionnaire to get the perspective from the selected banking practitioners (decision makers) on their experiences of the relationship between the economic activity and NPL.

The general result from those studies reveals that it has a negative relationship between GDP and NPL whereby the increase in GDP leads to decrease NPL. Research conducted by Shu (2002) in the case of Hong Kong reveals those bad loans as a fraction of total lending rise with the fall of economic growth. It means that the downturn economy leads the inability of the firms (borrowers) to repay back the loan and hence NPL increases. The similar study did by Festic and Beko (2008) in the country of Hungary and Poland. It argues that periods of economic growth and strong demand for a country’s exports have a positive effect on the domestic corporate sectors. At the time of the economic boom, corporates are performing, and it is creating the ability to repay back the loan, and therefore NPL decreases. The other study concerning this relationship can found from work conducted by Zeman and Jurca (2008) in the case of Slovakia. It found out that the growth of GDP leads to decrease NPL in the long run.

While those three studies are utilizing the secondary data to confirm the
relationship, there is another study conducted by Farhan, et al. (2012) to gather more information from the selected bankers in Pakistan. This review is essential, as it is the confirmation from the bankers’ practitioners on the GDP and NPL interactions. The result suggests that Pakistani bankers perceive that growth in GDP has a significant negative relationship with the NPL. From the studies above, the general overview of the relationship is that increase in GDP will decrease the NPL. It suggests that when the economy is improving, the revenue obtained from the corporates and income received by individuals creates positives effects on the loan capacity hence NPL will go down.

The relationship between interest rate and NPLs is apparent. Higher interest rates put borrowers in a problematic situation. Business might not be able to afford the higher payments resulting from an interest rate increase, and as a result, NPLs increase. Hence, the relationship between these two variables is positive. Studies regarding this issue have done by Festic and Beko (2008); Farhan et al. (2012); Jakubik (2007); Bofondi and Ropele (2011); Zeman and Jurca (2008); Shu (2002). About the relationship between price and NPLs, a study by Farhan et al. (2012) showed that a positive relationship exists between the two. A price increase would put the borrower in a better position since the real value of the loan decreases. Meanwhile, a study by Festic and Beko (2008) looked at the relationship between the exchange rate and NPL in several central European countries such as Hungary, Poland, the Czech Republic and Slovakia. All of the results showed a significant relationship although the relationship was not consistent between countries. All previous studies gathered in this research focuses on the conventional banks in various countries such as MENA region, countries in Europe, etc. So far there is no study looking at the case of Islamic banks. This study utilizes the Islamic banking as the case study, and moreover, the conventional banks also taken into account. Therefore, the current research gains its importance not only for central bank in a country, which adopts dual banking system (conventional and Islamic bank) such as in Indonesia

This study extends the previous research by taking the Islamic banking as the case. This type of banking differ mainly on the contract adopted in various banking instruments both funding and financing which open a new landscape on the risk management, policies issues, etc. Furthermore, the result of this study stimulates the future research for example whether Islamic banks can transmit the monetary policy into the real sector or other research for instance risk mitigation on each type of financing contract in Islamic banks such as Murabaha, mudharabah, etc. This ensures the extension of the new knowledge.
Method

The data utilized covers the period from January 2004 to September 2014 (number of observations = 129). Data included in this study started from the earliest data published by Bank Indonesia (central bank of Indonesia) until the last data when the study begins. The total number observation which is 129 is sufficient for the adopted method. The study utilizes Cointegration and impulse response function (IRF) due to the following reasons. The long-run relationship is one of the aims of this study. Technically, it seeks the determinants of the NPL and NPF in the long run. This factor is essential, particularly for the central bank as the regulator to create policies to develop real sector by looking at the NPL and NPF performance.

IRF is adopted to look into the short run relationship. It enables to see the respond of NPL and NPF on the shock of the each determinant used in this study. Therefore, the adopted methods ensure the comprehensiveness of the analysis. As explained above, two models being examined, namely non-performing financing and non-performing loan. For the NPF model, the variables of capital adequacy ratio Sharia (CARS), financing rate (FR), Islamic financing (LIFIN), industrial production index (LIPI), consumer price index (LCPI), Islamic banking assets (LIBASSET), and exchange rate (LXRATE) are used as determinants for non-performing financing (NPF). To provide a comparison, we continue with a discussion of non-performing loans (NPL). For which the variables of capital adequacy ratio (CAR), interest rate (INT), conventional loans (LCLOAN), industrial production index (LIPI), consumer price index (LCPI), Islamic banking asset (LIBASSET), and exchange rate (LXRATE) are adopted.

The models of NPF and NPL as follows:

\[
\text{NPF} = f (\text{CARS, FR, LIFIN, LIPI, LCPI, LIBASSET, LXRATE})
\]
\[
\text{NPL} = f (\text{CAR, INT, LCLOAN, LIPI, LCPI, LCBASSET, LXRATE})
\]

This first test of order of integration is very important in the time series analysis. Failure to do this test could lead to spurious regression in which the result shows a relationship between the variables of X and Y as significant, whereas a priori there should be none. So to test the order of integration of the variables, two types of unit root tests were performed for this study. These are the Augmented Dickey Fuller (ADF) Test and the Phillips-Peron (PP) Test.

The unit root test of ADF is an extension of the Dickey Fuller (DF) test. The unit root test of PP was developed as a generalization of the DF procedure. PP allows for a fairly mild assumption concerning the distribution of error. Whereas DF assumes independence and homogeneity, the PP test allows the disturbances to
be weakly dependent and heterogeneously distributed. The critical values for the PP test statistics are the same as those in the DF test.

Economically speaking, co-integration exists when two (or more) series are linked to form an equilibrium relationship spanning the long run, although the series may contain stochastic trends (non-stationary). They will nevertheless move closely together over time and difference between them will be stable (stationary) (Harris, 1995). This definition implies that even though examining non-stationary variables may result in spurious regression, if the residual of the model is found to be stationary then the variables are said to have co-movement in the long run or a long-term equilibrium relationship.

It is now necessary to outline the VAR order selection, or the selection of relevant lag length in the modeling of VAR. Some of the criteria used in selecting the VAR lag length for each variable are, among others, the Akaike's Information Criterion (AIC) and the Schwarz Information Criterion (SIC). The lag length used should be long enough to confine the dynamics of the system. However, it should not be so long as to exhaust the degrees of freedom.

Lastly, IRF accounts for the effect of shocks at a particular time on the future values of a variable in a dynamic system (Pesaran and Shin, 1998). The current study looks at the responses of the main variables, namely NPF and NPLs, to a shock in the various variables of CARS/CAR, FR/INT, LIFIN/LCLOAN, LCPI, LIBASSET/LCBASSET, and LXRATE.

Result and Discussions

This section discusses the results of the adopted model and continues with an analysis. As explained above, two models are examining, namely non-performing financing and non-performing loans. This study utilized the Augmented Dickey-Fuller (ADF) and Phillips Perron (PP) tests. The lag in the test equation is chosen based on AIC and SC. In all the cases, the test was conducted with intercept and trend & intercept. Table 2 reports the result of those tests. It can be seen that based on ADF unit root test, all variables CAR, CARS, LCBASSET, LCLOAN, LCPI, FR, LIBASSET, LIFIN, INT, LIPI, NPF, NPL, LXRATE contain the unit root. Namely, the null hypothesis of the presence of unit root cannot be rejected at 5% significance level especially for ADF level and intercept. However, the variables are stationary when first differenced (PP). We, therefore, conclude that they are I (1) variables. Therefore, for our analysis, this serves as a prerequisite for our co-integration test.
As can be seen in Table 3 and Table 4, trace statistics and max eigenvalue for NPF show two and one co-integrating equations, respectively. This means that in the long run, NPF and its determinants are found to be co-integrated. In short, the presence of co-integration between NPF and other variables provides evidence that these variables share a long-run relationship. Therefore, we can conclude that there is a long-run equilibrium governing the relationship between the variables.

### Table 3. Cointegration of NPF

**NPF = f(CARS, FR, LIFIN, LIPI, LCPI, LIBASSET, LXRATE)**

| Model | Null Hypothesis | Trace Statistics | 0.05 Crtel Value | Max-Eigen Statistics | 0.05 Crtel Value | Result |
|-------|-----------------|------------------|------------------|----------------------|------------------|--------|
| r ≤ 1 | 0.273274        | 133.2185         | 125.6154         | 39.58147             | 46.23142         | coint equation in TT and ME |
| r ≤ 2 | 0.221891        | 93.63707         | 95.75366         | 31.11015             | 40.07757         |        |
| r ≤ 3 | 0.202059        | 62.52692         | 69.81889         | 27.98943             | 33.87687         |        |
| r ≤ 4 | 0.140929        | 34.5375          | 47.85613         | 18.83599             | 27.58434         |        |
| r ≤ 5 | 0.074598        | 15.70151         | 29.79707         | 9.613326             | 21.13162         |        |
| r ≤ 6 | 0.039879        | 6.088183         | 15.49471         | 5.046261             | 14.2646         |        |
| r ≤ 7 | 0.008367        | 1.041921         | 3.841466         | 1.041921             | 3.841466         |        |
A similar result was found for conventional banks. The results show that co-integration exists between non-performing loan (NPL) and capital adequacy ratio (CAR), interest rate (FR), conventional loan (LCLOAN), industrial production index (LIPI), consumer price index (CPI), conventional banking assets (LCBASSET), and exchange rate (LXRATE). Table 5 and Table 6 reveals that the trace statistics and the max eigenvalue statistics provide five and two co-integrating equations, respectively. Hence, the results suggest that the variables in NPL equation share a long-run relationship.

Table 4. Normalized Co-integration Equation for NPF Model

| NPF | CARS  | FR    | LIFIN  | LIPI   | LCPI   | LIBASSET  | LXRATE |
|-----|-------|-------|--------|--------|--------|-----------|--------|
| 1   | 0.586343 | 0.782149 | -98.8115 | -69.8786 | 42.88138 | 106.3613  | 85.91561 |

Based on the result, long run cointegrating vectors, several notable points need to be highlighted. In the long run, capital adequacy seems to be significant. The positive and significant role of the capital adequacy ratio for Islamic banks (CARS) (t-stat= -1.64) indicates that an increase in NPF will likely follow an increase in CARS. Similarly, for the conventional model, the CAR shows a positive correlation with NPL (t-stat= -6.68).

Table 5. Co-integration of NPL

NPL = f (CAR, INT, LCLOAN, LIPI, LCPI, LCBASSET, LXRATE)

| Model | Null Hypothesis | Trace Statistics | 0.05 Crtel Value | Max-Eigen Statistics | 0.05 Crtel Value | Result |
|-------|----------------|------------------|-----------------|----------------------|-----------------|--------|
| r ≤ 0 | 0.40309  | 230.21 | 159.5297 | 63.98262 | 52.36261 | 5 and 2 cointegration in TT and ME |
| r ≤ 1 | 0.340265 | 166.2274 | 125.6154 | 51.57376 | 46.23142 |
| r ≤ 2 | 0.273401 | 114.6537 | 95.75366 | 39.60319 | 40.07757 |
| r ≤ 3 | 0.177551 | 75.05047 | 69.81889 | 24.23815 | 33.87687 |
| r ≤ 4 | 0.167873 | 50.81232 | 47.85613 | 22.78754 | 27.58434 |
| r ≤ 5 | 0.125041 | 28.02478 | 29.79707 | 16.56371 | 21.13162 |
| r ≤ 6 | 0.055658 | 11.46108 | 15.49471 | 7.101057 | 14.2646 |
| r ≤ 7 | 0.03455 | 4.36002 | 3.841466 | 4.36002 | 3.841466 |
Interest Rate (INT) seems to relate positively and significantly with NPL. This result implies that when the rate increases, NPL tends to follow in the same direction. This effect is expected and can be justified theoretically. The documented relationship between Islamic financing and NPF shows a negative and significant relationship, while conventional loan suggests a not considerable relationship to NPL. The t-stat of Islamic financing shows the variable (LIFIN) to be significantly related to NPF (t-stat=-4.42), and the variable of conventional loans is displayed to insignificantly associated with NPL (t-stat= 0.24).

| NPL  | CAR   | INT   | LCLOAN | LIPI  | LCPI  | LCBASSET | LXRATE   |
|------|-------|-------|--------|-------|-------|----------|----------|
| 1    | 0.990607 | 0.798827 | -0.71187 | -6.8452 | -1.32765 | 4.360558 | -6.40997 |
| St-error | -0.1483 | -0.25501 | -2.85671 | -3.1057 | -1.06703 | -4.24624 | -1.54087 |
| t-stat | -6.67975 | -3.13253 | 0.249194 | 2.20407 | 1.244245 | -1.02692 | 4.159969 |

About the role of the industrial production index (LIPI) for both types of banks, it noted that LIPI has the same effect on NPL and NPF. The relationship of LIPI to both NPF and NPL is negative and significant, with t-stats of 4.43 and 2.2, respectively. This result means that an increase in LIPI will follow by a decrease in NPL and NPF.

Price is shown to have a long run-effect on NPF but not NPL, with t-stats of 6.5 and 1.24, respectively. This result means that when the price increases, NPF tends to increase but NPL does not. Regarding size, the variable of Islamic banking assets seems to have a significant positive effect on NPF (t-stat= -4.905), while this is not the case with conventional banking assets (t-stat= 1.02). Lastly, exchange rate seems to have a different impact on the different types of banks in the long run. For the NPF model, an increase in the exchange rate (depreciation) will follow by an increase in NPF (t-stat= -7.5). Conversely, an increase in exchange rate will cause a decrease in NPL.

An impulse response function (IRF) maps out the response of a variable in the VAR system to shocks in other variables (Gujarati, 2003). In other words, it is used to see how a shock in one variable is transmitted to other variables through a dynamic VAR structure, besides directly affecting the concerned variable itself. A generalized impulse response is applied in all cases, since it does not depend on the VAR ordering (Evies 5 User Guide, 2005).

The IRF results show that shocks in Islamic financing and conventional loans lead to a fast and negative response in NPF/NPL (Figure 1 and Figure 2). A shock in
size also leads to an adverse reaction in NPF and NPL. This means that an increase in size would reduce the NPL and NPF. Shocks in FR/INT and LCPI do not cause a good response from NPF and NPL in the short run. Similarly, NPF or NPL show no reaction by the shock of IPI. This suggests that lag is required for the shock of IPI to have an impact on NPF and NPL. For capital, the IRF has a different effect on NPF than NPL. The same is true for the exchange rate.

Figure 1. Impulse Response Function of NPF

In this study, economic performance (GDP) is represented by the industrial production index (LIPI) following Sukmana and Kassim (2010). When the economy grows, LIPI increases. In this study, LIPI is shown to have the negative relationship with NPF, which means that when the economy booms, businesses are earning more revenues, which later increases their ability to repay the financing. Hence, non-performing financing decreases. For the last three years, Indonesian
economic growth has stood at around 5.7% to 6.5% (Bank of Indonesia, 2007). As such, it can regard as a country with high economic growth, especially given the low economic growth of the European countries. With high economic growth, prospective businesses are expanding their activities by requesting loans from banks (both conventional and Islamic). Repayment of loans or financing to those banks should not face many difficulties, as overall economic performance in Indonesia is rising. This result is consistent with the studies done by Shu (2002); Jakubik (2002); Festic and Beko (2008); Zeman and Jurca (2008); Farhan et al. (2012). However, in the short run, IR shows not the significant effect of the financing rate and interest rate to the NPF and NPL respectively.

Figure 2. Impulse Response Function of NPL

Regarding the relationships of FR and INT to NPF and NPL, respectively, this study shows that the connections are different. The interest rate positively correlates
with NPL, but such is not the case with FR and NPF. This is understandable since the increase in interest rate would increase defaults on loan payments. In this case, the increase in interest rate would lead to a higher amount of money being paid by businesses to banks, creating a burden on the borrower. As a result, some of them would be unable to pay. Hence it increases the number of payments by default. Furthermore, banks can increase their interest rate at will, following the monetary rate before or during the loan period. The result supports much of the literature, including studies by Berger and De Young (1997); Jakubik (2007); and Bofondi and Ropele (2011).

The fact that FR is not significantly related to the NPF shall also explain once the types of financing contracts adopted in Islamic banks described. Similar to Islamic banking elsewhere, financing contract types in Indonesia dominant by the murabahah (buy and sell agreement), whereby banks will buy the asset and sell it to the customer with margin and a definite term. During the term, the margin cannot be changed whatsoever or else the contract will be invalid. The margin is fixed from the beginning of the signed contract to the end of the murabahah term, even if the interest rate in the conventional bank increases. Given the fixed rate, NPF can be expected to be low. In contrast, an increase in the interest rate during the term of a conventional loan may directly increase NPL. In Indonesia, murabahah represents more than 58% of the total financing given by Islamic banks (Islamic banking statistics, 2014). Hence, this domination perhaps leads to the insignificance of the relationship between FR and NPF.

Price is positively related to NPF, with an increase in price leading to an increase in NPF. The previous literature showing the negative relationship between price and NPL, including work by Shu (2002); Zeman and Jurca (2008), suggests that an increase in price would create the loan repayment value to decrease in real terms. Hence, in this case, the borrower or fund recipients are at an advantage. This result leads to lower NPL since the borrower will have a greater ability to pay back the loan. However, such is not the case with Islamic banking, where the increase in price increases the NPF. LPPS (2005; 2006) reports that an increase in general price due to fuel subsidy reduction increased the inability to repay the financing. In the short run of IRF, the shock of price seems to increase both NPF and NPL.

Perhaps the type of businesses financed by Islamic banks can explain this result. Based on data from Bank Indonesia (Islamic banking statistics, 2014) from 2005 to 2013, the financing provided to small and medium enterprises (SMEs) ranged from 55% to 77%. The rest was given to large enterprises. SMEs are companies in which the executor is also the owner, and the assets of the company are the assets of the owner. Thus, SMEs may not have proper separation of the asset.
These sectors dominated by the lower and middle-income segments, which are more sensitive to increases in price. When the price of basic needs increases, SMEs use the money/asset from the companies as opposed to their own money. As a result, they may not be able to pay back the loan. This result could perhaps explain the positive relationship between price and NPF.

In this study, Islamic financing is shown to have a negative relationship with NPF, meaning that an increase in financing will cause NPF to decrease. However, the same is not the case for conventional loans. The fact that increases in Islamic financing decreases NPF perhaps due to the regulation by the central bank of Indonesia (Bank Indonesia) applied to the Islamic banking industry. The rule in this case is on the reserve requirement, which is not based on the number of deposits collected but instead on the financing-to-deposit ratio (FDR). This policy aims to return banks to their primary role as financial intermediaries. Lowering the reserve required by central banks rewards the banks functioning in this fundamental task. Conversely, banks that were paying more for the reserve requirement punished fail. Paying more for this reserve is unexpected, and therefore banks need to maintain the FDR by providing more financing. Further study can be read in Sukmana and Kholid (2013).

Loans from conventional banks are shown to have a negative relationship (in the short run of IRF) with NPL, meaning that when loans increase, NPL will go down. This result is consistent with studies by Kwan and Eisenbeis (1997); Boudriga et al. (2009b). However, in the long run, there is no significant relationship seen between the two.

Size is shown to have a negative impact on both NPF and NPL in the short run, as demonstrated by IRF, supporting the study done by Shrievs and Dahl (1992). This result suggests that when there is an increase in the assets of Islamic banks and conventional banks, there is a decrease in NPF and NPL, respectively. Conversely, a decline in assets will lead to high NPF. Big banks have a greater ability to equip themselves with sophisticated information technology to facilitate customer transactions. Such advanced technology provides customers with any banking transaction required and even includes software for credit scoring, which allows account officers to assess a business’s risk more accurately. Furthermore, given the large size of banks, such technology upgrades the skills of risk assessors, as a way to address the risk involved. Both Islamic and conventional banks are utilizing technology to do this.

Capital adequacy in both types of bank seems to have the same impact on NPF/NPL. Both coefficients are positive with a significant t-stat result. This result conflicts with many other studies, including those of Boudriga et al. (2009a); Berger
and De Young (1997). The exchange rate is shown to have a negative relationship with the NPL. When the rupiah depreciates (increase in value/USD), NPL decreases. This can explain by the role of the exporters. In the case of depreciation, the exporter tends to export more since they will receive more rupiah for the same amount of USD. However, this is not the case for Islamic banks, where it is found that the relationship between the two is positive.

The Islamic banking industry, which has been in existence in Indonesia for more than two decades, also contributes to Indonesian economic development. Despite the fact that the current market share is still around 5%, the growth of the sector by more than 30% shows the acceptance of this new industry by people and businesses at large. As the largest Muslim country, there is a necessity for interest-free financial institutions earmarked for Muslim and people in general. Not only Muslim but also non-Muslims need this bank, since Islamic banks have unique features that suit with different risk appetites than conventional banks. For example, certainty regarding the margin assure in the murabahah concept. Therefore, ensuring the soundness of Islamic banking performance is also important in providing continued support to the Indonesian economy.

The government must maintain stable economic performance (GDP) to keep the NPF and NPL low. The relationship of Islamic financing to NPF is negative, which means that as Islamic financing increases, the NPF decreases. This suggests that when providing more financing, Islamic banks have been selecting the businesses appropriately to ensure their ability to pay back the financing. This is demonstrated by a high financing-to-deposit ratio while keeping the NPF low. One of the reasons for Islamic banks to provide more financing to businesses is to avoid the higher required reserve payment to the central banks. In the case of Indonesia, the Islamic banking industry is needed to provide more reserve, unless their FDR is above 80%.

This policy aim at ensuring the role of banks as financial intermediaries, to eventually supports the real sectors. In this case, FDR used as a proxy for financial intermediation. High FDR refers to a high level of financial intermediation and vice versa. While giving more financing, Islamic Banks also need to maintain the quality of financing to provide a competitive margin for depositors despite the bank’s operational expenses. The fact that Islamic banks can keep an average FDR above 80% while maintaining NPF at less than 5% shows that Islamic banks have performed well in their role as financial intermediaries and terms of quality of financing. Regulation by Bank Indonesia on this matter seems to be effective and also imposed on conventional banks (Sukmana and Kholid, 2013).

The negative relationship between the overall economic performance (GDP)
and NPF suggests a recommendation for practitioners. Islamic Banks should equip with an early warning system showing international and domestic economic performance. In the case that a tendency toward economic decline emerges, financing disbursement should be reduced to avoid an increase in NPF. Further research should focus on the NPF in different sectors about the macro and micro-economic variables, to determine the sensitivity of those economic sectors.

Conclusion
The banking sector plays the major role in the economic development in Indonesia. Given the country's underdeveloped capital market, the banking sector is still the primary channel for the individual consumer and business investment. Therefore, a sound-banking sector is crucial for the overall development of Indonesia's economy. Of many other indicators, non-performing financing (NPF) in the case of Islamic banks and NPL in the case of conventional banks, are essential.

For this reason, both non-performing financing and non-performing loans chosen as essential variables for looking at the performance of the banking industry. Based on the existing literature on this topic. This study identifies factors which may influence NPF and NPL, namely the capital adequacy ratio (for Islamic and conventional banks), financing rate/interest rate, Islamic financing/conventional lending, industrial production index, consumer production index, Islamic/conventional banking assets, and exchange rate.
