Abstract

A cDNA clone encoding a 64-amino acid type 3 metallothionein protein, designated GhMT3a, was isolated from cotton (Gossypium hirsutum) by cDNA library screening. Northern blot analysis indicated that mRNA accumulation of GhMT3a was up-regulated not only by high salinity, drought, and low temperature stresses, but also by heavy metal ions, abscisic acid (ABA), ethylene, and reactive oxygen species (ROS) in cotton seedlings. Transgenic tobacco (Nicotiana tabacum) plants overexpressing GhMT3a showed increased tolerance against abiotic stresses compared with wild-type plants. Interestingly, the induced expression of GhMT3a by salt, drought, and low-temperature stresses could be inhibited in the presence of antioxidants. H₂O₂ levels in transgenic tobacco plants were only half of that in wild-type (WT) plants under such stress conditions. According to in vitro assay, recombinant GhMT3a protein showed an ability to bind metal ions and scavenge ROS. Transgenic yeast overexpressing GhMT3a also showed higher tolerance against ROS stresses. Taken together, these results indicated that GhMT3a could function as an effective ROS scavenger and its expression could be regulated by abiotic stresses through ROS signalling.

Key words: Abiotic stress, antioxidant, GhMT3a, ROS, transgenic tobacco, yeast.

Introduction

Drought, high salinity, and low temperature are three important abiotic stresses that are commonly encountered by plants growing in their native environments. To survive these challenges, plants have developed elaborate mechanisms to perceive external signals and to manifest adaptive responses with the proper physiological and morphological changes (Shinozaki and Yamaguchi-Shinozaki, 2000; Zhu, 2002). The three kinds of stresses are often interconnected and induce similar cellular damage, or often activate similar cell signalling pathways and cellular responses (Shinozaki and Yamaguchi-Shinozaki, 2000; Knight and Knight, 2001; Xiong et al., 2002; Hu et al., 2008). One of the most common and crucial consequences is the generation of ROS in plants, which can elicit a potentially damaging oxidative burden on cellular constituents and/or act as signals for engaging mechanisms that ameliorate oxidative stress (Alvarez et al., 1998; Foyer and Noctor, 2005; Mittler, 2002).

The oxidative burst, a transient increase of ROS production, predominantly superoxide (O₂⁻) and hydrogen peroxide (H₂O₂), is the first biochemical response of plants to abiotic stress and can cause extensive cell injury or death (Coelho et al., 2002; Mittler, 2002; Joo et al., 2005). On the other hand, ROS play a central role in many signalling pathways in plants involved in stress perception, photosynthesis regulation, pathogen response, programmed cell death, and plant growth and development (Apel and Hirt, 2004; Davletova et al., 2005; Miller et al., 2007). Although the deleterious effects of ROS have long been known, knowledge on the molecular mechanisms of ROS-mediated...
gene regulations is limited and whether they play different roles in plant stress response have remained largely unexplored (Kobayashi et al., 2007).

Metallothioneins (MTs) are defined as a family of proteins with the characteristics of low molecular weight, high cysteine (Cys) residue content, and metal-binding ability. They have been widely found in animals, plants, fungi, and cyanobacteria, and are divided into three classes based on the arrangement of Cys residues. All MTs identified from plants so far belong to Class II and have been further grouped into four types according to Cys residue distribution (Robinson et al., 1993; Palmiter, 1998; Cobbett and Goldsborough, 2002).

In animals, MTs are ubiquitous proteins associated with numerous cellular functions, including the regulation of metal homeostasis in cells and the response to metal toxicity and oxidative stress (Mattie and Freedman, 2004; Zatta et al., 2005; Stankovic et al., 2007). In fungi, MTs have been proposed to be primarily involved in the response to metal toxicity or as general stress proteins (Lanfranco et al., 2002; Tucker et al., 2004). Recently, increasing numbers of reports have indicated that plant MTs may play important roles as they do in animals and fungi (Adams et al., 2002; Cobbett and Goldsborough, 2002; Chiang et al., 2006; Zhigang et al., 2006). In addition, plant MTs are involved in some important developmental processes, such as fruit ripeness, root development, and suberization (Chatthai et al., 1997; Clendennen and May, 1997; Mir et al., 2004; Moyle et al., 2005; Yuan et al., 2008). In Arabidopsis, it has been demonstrated that different types of MTs exhibit distinct and overlapping functions in maintaining the homeostasis of essential transition metals, detoxification of toxic metals, and protection against intercellular oxidative stress (Robinson et al., 1996; Murphy et al., 1997; Garcia-Hernandez et al., 1998; Miller et al., 1999; Kiddle et al., 2003; Lee et al., 2004).

Cotton is one of the most important fibre and oil crops, and its growth and yield are severely inhibited in high salinity soil, especially at the germination and emergence stages (Gouia et al., 1994; Gossett et al., 1996; He et al., 2005). To identify genes whose expression is correlated with salinity stress in cotton, a cDNA library was constructed by using mRNA isolated from salt-induced seedlings of a salt-tolerant cotton cultivar, ZM3, and screened by differential expression (Zheng et al., 1998). Positive clones identified from plants so far belong to Class II and have been further grouped into four types according to Cys residue distribution (Robinson et al., 1993; Palmiter, 1998; Cobbett and Goldsborough, 2002). In addition, plant MTs are involved in some important developmental processes, such as fruit ripeness, root development, and suberization (Chatthai et al., 1997; Clendennen and May, 1997; Mir et al., 2004; Moyle et al., 2005; Yuan et al., 2008). In Arabidopsis, it has been demonstrated that different types of MTs exhibit distinct and overlapping functions in maintaining the homeostasis of essential transition metals, detoxification of toxic metals, and protection against intercellular oxidative stress (Robinson et al., 1996; Murphy et al., 1997; Garcia-Hernandez et al., 1998; Miller et al., 1999; Kiddle et al., 2003; Lee et al., 2004).

Northern blot analysis

Total RNA was extracted using the RNeasy Plant Mini Kit (Qiagen, Fremont, CA, USA). RNA samples for each experiment were analysed in at least two independent blots. Hybridization was performed in the same manner as the cDNA library screening. The specific GhMT3a cDNA fragment was labelled with \( \alpha^{32}\text{P}\)dCTP by the Prime-a-Gene labelling system from Promega, and used for the hybridization probe.

Materials and methods

Plant materials, growth conditions, and treatments

Seeds of cotton (G. hirsutum L.) ZM3 were provided by the Chinese Academy of Agricultural Sciences. Seedlings were grown in MS-liquid medium in a growth chamber for 9 d with 300 \( \mu\)m M \(-2\) s\(^{-1}\) light intensity and day/night temperatures of 25 °C. For different stress treatments, uniformly developed seedlings were transferred into liquid medium containing the indicated concentrations of NaCl, PEG, CuSO\(_4\), ZnCl\(_2\), ABA, ethylene, H\(_2\)O\(_2\) or PQ for 12 h. For the low temperature treatment, the seedlings were transferred to an incubator at 4 °C for 12 h. To study the effect of N-acetyl cysteine (NAC) on the induced expression of GhMT3a by stresses, the seedlings were transferred into liquid medium containing the indicated concentrations of NAC, together with the indicated concentrations of NaCl, PEG or a temperature of 4 °C. Then, cotyledons were harvested at 0, 1, 3, 6, and 12 h points directly into liquid nitrogen and stored at −80 °C for later use.

cDNA library construction and screening

Poly(A)\(^+\) RNA (0.5 μg) isolated from cotyledons of ZM3 seedlings treated with 300 mM NaCl for 24 h was used to synthesize first-strand cDNA, which was then amplified by long-distance PCR according to the manufacturer’s protocol (SMART\(^\text{TM}\) cDNA Library Construction Kit, Clontech, Mountain View, CA, USA). The double-stranded cDNA was digested by the SfiI enzyme, and then fractionated by Chroma Spin-400. Fragments longer than 500 bp were cloned into SfiI-digested dephosphorylated λTriplEx2 arms with T4 DNA ligase. The recombinants were packaged in vitro with Packagene (Promega, Madison, WI, USA). The cDNA library was screened by differential hybridization (once with an untreated cotyledon cDNA probe, once with a 300 mM NaCl-treated cotyledon cDNA probe). Plaques at a density of 10° plaques/plate (15 cm diameter) were transferred onto the membrane. Prehybridization, hybridization, and washing were performed as described previously (Zheng et al., 1998). Positive clones were plaque purified by two additional rounds of plaque hybridization with the same probes. Clones exclusively or preferentially hybridized by the NaCl-treated cotyledon cDNA probe were selected. Among these, one cDNA clone, GhMT3a, is described in this paper.
Analysis of transgenic tobacco plants under various stress conditions

Tobacco (Nicotiana tabacum cv. NC89) seedlings were grown on sterile MS medium and were used for leaf disc transformation. The Agrobacterium strain LBA4404 and the pBI121-based binary vector pHAGSK were used for transformation. The Gus gene of the vector was replaced with GhMT3a at the XbaI and SacI restriction sites. The Agrobacterium-mediated transformation and regeneration procedures were as previously described by Kano-Murakami et al. (1993).

T0 transgenic tobacco plants were identified by PCR to amplify the nptII gene with specific primers (5'-CGCAT-GATTGAAACAGATGG-3' and 5'-TCCCCGCTCAGAA-GAACTCGTC-3'). The corresponding T1 transgenic tobacco seedlings segregated at a ratio of ~3:1 (resistant:-sensitive) were selected to propagate the T2 generation, which was used for further analysis. Every 16 uniformly developed seedlings of transgenic and WT tobacco plants were treated with 200 and 300 mM NaCl for 20 d, 4 °C for 3 d, and 25% PEG for 15 d, respectively. The seedlings treated by NaCl and PEG were grown at 25 °C. These experiments were performed three times. The seedlings were photographed after recovery at 25 °C for 2 d.

Quantification of H2O2 levels

Cotyledons of cotton seedlings (1 g fresh weight) were homogenized in 5 ml cold acetone in a mortar with silica sand (Ferguson et al., 1983). The extract and washings were centrifuged at 1250 g for 15 min and the chlorophyll contents were adsorbed by activated carbon. Then 200 μl supernatant were added to 1 ml of reaction buffer [0.25 mM FeSO4, 0.25 mM (NH4)2SO4, 25 mM H2SO4, 1.25 mM xylenol orange, and 1 mM sorbitol] at room temperature for 1 h. H2O2 levels were quantified at 560 nm absorbance, and H2O2 and H2O2 levels were calculated by reference to standards (He et al., 2000; Suharsono et al., 2002).

Production of recombinant GhMT3a

A fragment containing the entire open reading frame of GhMT3a was cloned by PCR into the BamHI site of the E. coli expression vector pGEX4T-1 (Amersham Pharmacia Biotech, Hong Kong, China). To overexpress GST-GhMT3a and the control GST proteins, the pGEX and pGEX-GhMT3a plasmids were transformed into BL21 E. coli cells. Transformed cells were grown to OD600 0.8 at 37 °C before expression of the recombinant proteins was induced by the addition of 1 mM isopropyl β-D-thiogalactoside, followed by growth at 25 °C for 4 h. The cells were harvested by centrifugation and lysed by sonication, as described previously (Valls et al., 2001). The GST and GST-GhMT3a proteins in the recovered supernatant were purified by batch affinity chromatography with glutathione-Sepharose 4B (Amersham Pharmacia Biotech, Hong Kong, China) according to the manufacturer’s instructions. The purified proteins were dialysed with three changes against 500 vols of phosphate-buffered saline overnight at 4 °C and concentrated by Centriprep Concentrators. The tag of concentrated GST-GhMT3a was digested by Thrombin Cleavage Capture Kit (Novagen, San Diego, CA, USA). To prevent protein oxidation, the buffer solutions were bubbled with pure nitrogen gas in all the purification steps.

Hydroxyl radical scavenging assays

For hydroxyl radical scavenging assays, antioxidant-mediated competitive inhibition of the salicylate hydroxylation by hydroxyl radicals was performed as described previously (Smirnoff and Cumbes, 1989).

Functional analysis of GhMT3a in yeast

Saccharomyces cerevisiae strain W303 was used as the wild type. Yeast strains were routinely cultured in YPD (1% yeast extract, 2% peptone, and 2% dextrose) or synthetic dropout (SD) media with appropriate supplements at 30 °C. A GhMT3a expression vector was made by subcloning the GhMT3a gene by PCR into a pYES2 shuttle vector (Invitrogen, San Diego, CA, USA), which contains the Ura3 selection marker and is driven by a GAL1 promoter. Yeast transformation was carried out using the standard lithium acetate method (Madeo et al., 1999). Growth assays were performed according to a method described previously by Bass and Rao (1999) by inoculating 2 μl of saturated seed culture into a tube with 3 ml of selective medium (2% galactose, 0.67% yeast nitrogen base without amino acid, and 0.077% Ura DO Supplement, pH 4.0), containing 2 mM H2O2 or 2 mM PQ and the absorbance at 600 nm was measured. Growth on selective plates was performed as described previously (Yokoi et al., 2002).

Results

Characterization of a NaCl-induced MT cDNA clone in cotton

A cDNA clone, GhMT3a (AY857933), was isolated from a NaCl-induced G. hirsutum cotyledon cDNA library by differential hybridization screening to identify genes involved in salt stress. The full sequence of the GhMT3a cDNA consisted of 499 nucleotides, encoding a polypeptide approximately 6.6 kDa of 63 amino acids. The N-terminal and C-terminal domains contain 4 and 6 Cys residues, respectively, separated by a central Cys-free spacer. In agreement with other higher plant MTs, all the Cys residues are located in the N- and C-terminal domains of GhMT3a. Multiple alignments also showed that GhMT3a shared high homology with many MTs from other plant species (Fig. 1).

To obtain clues about the evolutionary history of GhMT3a, a phylogenetic tree was constructed based on the similarities of deduced amino acid sequences of 67 available MT genes from various plant species. Consulting Cobbett and Goldsbrough’s classification of plant MT, we also divided plant MTs into four types (Fig. 2), and GhMT3a...
To elucidate if the regulation of these MTs are indicated to the right of the sequences. MTs are as follows: Identical or conserved amino acids are shaded in dark or grey, respectively. The accession numbers in GenBank of other plant type 3 sequence alignment is optimized by inducing gaps using DNAman software. Conserved cysteine residues are indicated by the letter C.

Damage in plants (Alvarez, and hydroxyl radicals, which, in turn, results in cell accumulation of ROS such as superoxide, hydrogen peroxide, and hydroxyl radicals, which, in turn, results in cell damage in plants (Alvarez et al., 1998; Apel and Hirt, 2004). To elucidate if the regulation of GhMT3a expression under conditions of drought, salt, and cold stress is under the control of ROS, the mRNA levels of GhMT3a in cotton seedlings treated with solutions of 10 mM H2O2 and 100 µM paraquat (PQ) as sources for the generation of ROS, were examined first. The results showed that just as in the cases of drought, salt, and cold stresses, both H2O2 and PQ significantly enhanced the accumulation of GhMT3a transcripts (Fig. 4A). Thereafter, the cotton seedlings were treated with 300 mM NaCl, 25% PEG, 4 °C, 10 mM H2O2, and 100 µM PQ together with the antioxidant N-acetyl cysteine (NAC) and the levels of GhMT3a transcripts and H2O2, respectively, were examined. The results indicated that NAC, as a kind of antioxidant, could effectively reduce not only ROS accumulation (Fig. 4B) but also the GhMT3a transcript level induced by salinity, drought, and cold stresses (Fig. 4C), suggesting that GhMT3a might be regulated by ROS production under such abiotic stress conditions.

**Overexpression of GhMT3a in tobacco plants improves tolerance to abiotic stress**

To confirm the in vivo functions of the GhMT3a gene during abiotic stress in plants, ectopic expression of the GhMT3a gene was carried out in tobacco. A total of 17 transgenic tobacco plants were obtained. Northern blot analysis showed that, although the transcriptional levels of the MT gene from individual tobacco plants varied, the signal intensity in transgenic plants was much stronger than that in wild-type (WT) plants (Fig. 5A). Sixty-four kanamycin-resistant T2 plantlets (from eight lines) were selected for the stress tolerance assay. Sixteen 4-week-old uniformly developed seedlings of transgenic and WT tobacco plants were treated with 4 °C, 25% PEG, 200 mM and 300 mM NaCl, respectively. As shown in Fig. 5C, the transgenic plants exhibited enhanced tolerance against high salinity, low temperature, and drought compared with WT plants. Although all plants showed wilting and dehydration of young leaves with a concomitant loss of chlorophyll, the damaging levels in transgenic lines were lower than those of WT lines. All transgenic tobacco plants were able to survive following recovery, whereas 82% of WT plants died.

**Fig. 1.** Comparison of the deduced amino acid sequences of Gossypium hirsutum MT3a with its homologues from other plant species. Sequence alignment is optimized by inducing gaps using DNAman software. Conserved cysteine residues are indicated by the letter C. Identical or conserved amino acids are shaded in dark or grey, respectively. The accession numbers in GenBank of other plant type 3 MTs are as follows: Gossypium hirsutum (GhMT3a, AY857933), Hordeum vulgare subsp. vulgare (CAD88266), Oryza sativa (AF001396), Oryza coarctata (AA68985), Actinidia chinensis (P43389), Carica papaya (CAA9624), Citrus unshiu (AAKO8209), Metroxylon sagu (ABA43635), Vitis vinifera (CAB85630), and Populus alba×Populus tremula var. glandulosus (BAD95608). The amino acid numbers of these MTs are indicated to the right of the sequences.
Moreover, H2O2 levels in transgenic tobacco plants were only half of those in WT plants under such stress conditions (Fig. 5B), indicating that the improved stress tolerance might be due to the change of ROS balance in tobacco by overexpressing GhMT3a.

The purified GST, GhMT3a, and GST-GhMT3a fusion proteins were determined in vitro for their ability to bind metal ions and function as a ROS scavenger. Because zinc is not a Fenton-active metal and
would not have deleterious effects on the purified proteins, metal binding experiments were performed using zinc (Tucker *et al.*, 2004; Hao and Maret, 2006; Qiao *et al.*, 2006). The results showed that with increasing concentrations of Zn\(^{2+}\), oxidation of the Cys residues in GhMT3a by 5,5'-dithiobis-2-nitrobenzoic acid (DTNB, a thiol-specific oxidizing agent) occurred more slowly, indicating that binding of Zn\(^{2+}\) to Cys residues inhibited the oxidation

(B) The H\(_2\)O\(_2\) levels in leaves of WT and transgenic tobacco lines under those stress conditions. Values are the mean obtained from three experiments, and error bars indicate SEM. (C) Plants were treated with or without salt solution every 2 d for 30 d; plants were grown at 25 °C as a control or at 4 °C for the low temperature for 3 d. Plants were treated with or without 25% PEG as a drought condition every 3 d for 20 d.
reaction (Fig. 6A). In the control experiment using Ca2+ to replace Zn2+, the presence of Ca2+ could not prevent GhMT3a from oxidation by DTNB (Fig. 6A). Moreover, when GhMT3a was incubated with 5-fold molar excesses of Zn2+, the DTNB oxidation was not retarded further, suggesting that the binding capacity per GhMT3a molecule would be no more than five Zn2+.

To determine the efficiency of GhMT3a as a ROS scavenger, its ability to inhibit superoxide- and hydroxyl radical-mediated oxidation in vitro compared with other antioxidants was measured. As shown in Fig. 6B, GST-GhMT3a displayed higher antioxidant activity against superoxide and hydroxyl radicals than the known antioxidants, including reduced glutathione (GSH) and thiourea at the same concentrations. Interestingly, GhMT3a protein without a GST tag also showed higher antioxidant activity than GSH, revealing the novel role of GhMT3a as an efficient antioxidant.

To confirm the function of GhMT3a as a ROS scavenger in vivo further, GhMT3a was transformed into *Saccharomyces cerevisiae* strain W303. The results indicated that the GhMT3a-overexpressing yeast cells were less sensitive to oxidants such as PQ and H2O2 than the control cells (Fig. 7), suggesting that GhMT3a could scavenge ROS effectively in eukaryotic cells.

### Discussion

High salinity, low temperature and drought are critical environmental factors that limit agricultural production worldwide, mainly by affecting plant growth and development. The cellular and molecular responses of plants to these stresses have been studied intensively (Hasegawa *et al.*, 2000; Thomashow, 1999; Xiong *et al.*, 2002). Oxidative stress occurs as an essential response when plants are challenged with abiotic stresses. Oxidative stress results from the disturbance in balance between ROS production and scavenging such as hydrogen peroxide, superoxide anions, and hydroxyl radicals that damage or kill cells by destroying lipids, nucleic acids, and proteins (Apel and Hirt, 2004; Hasegawa *et al.*, 2000; Thomashow, 1999; Xiong *et al.*, 2002).

![Fig. 6.](image_url) The ability of GhMT3a to bind metal ions and its function as a ROS scavenger in vitro. (A) GhMT3a (2 mM) was incubated with DTNB (100 mM) in HEPES buffer (nitrogen purged, 25 °C) and thiol oxidation monitored spectrophotometrically at 412 nm. As the concentration of metal ions in the solution increased, the rate at which this oxidation occurred slowed, which was indicative of metal binding to GhMT3a, which interferes with thiol oxidation. (B) Comparison of ROS scavenging activity between GST-GhMT3a, GhMT3a, and other known antioxidants. Inhibition of hydroxyl radical-mediated salicylate hydroxylation by antioxidants was shown. Values are the mean obtained from three experiments, and the error bars indicate SEM.

![Fig. 7.](image_url) Function of GhMT3a as a ROS scavenger based on overexpression in yeast. The pYES2 empty vector and pYES2-GhMT3a construct were transformed into wild-type strain W303. (A) Yeast strains in a concentration grade grown on selective plate with 2 mM H2O2 or 2 mM PQ; photos were taken after 72 h at 30 °C. (B) Growth of two transgenic lines (pYES2 empty, white squares; and pYES2-GhMT3a, black sequences) in liquid medium. Growth was detected by measuring the absorbance at 600 nm after culturing for 48 h at 30 °C in liquid medium containing 2 mM H2O2 or 2 mM PQ. Values are the mean obtained from three experiments, and the error bars indicate SEM.
Knight and Knight, 2001). To cope with different internal and external stresses, plants have developed a variety of adaptive mechanisms for survival by activating cascades or network events starting with stress perception and ending with the expression of many effector genes (Mittler, 2002; Xiong et al., 2002). It has been accepted that antioxidant defence systems, including non-enzymatic antioxidants such as ascorbate, reduced glutathione, and tocopherol, and enzymatic antioxidants such as SOD and CAT, play a crucial role in plants against various stresses. Previous studies demonstrated that the regulation of the concentrations of antioxidants and of the activities of antioxidant enzymes is an important mechanism for combating oxidative stress (Alscher et al., 2002; Blokhina et al., 2003; Heiber et al., 2007). However, because of the complexity and diversity of cell metabolism, other unknown antioxidant systems may exist in plant cells and need to be clarified.

MTs are cysteine-rich, low molecular weight intracellular proteins that were initially shown to regulate the metabolism of metals such as zinc, copper, and cadmium, and play a role in heavy metal tolerance (Lanfranco et al., 2002; Palmiter, 1998). Recently, a number of investigations have demonstrated MTs as being efficient scavengers of ROS production in animals (Li et al., 2006; Dong et al., 2007; Peng et al., 2007). During oxidative stress, MTs protect against ROS-induced DNA degradation with higher molar efficiency than glutathione (Jourdan et al., 2004). Plants also contain a multiple MT gene family in which different types may play distinct and overlapping biological roles by the regulation of gene expression or signalling networks. In Arabidopsis, all four types of MTs provided similar levels of Cu tolerance and accumulation to the yeast mutant Δcup1 (Lee et al., 2004; Guo et al., 2008). Cu\(^{2+}\), Ag\(^{+}\), Cd\(^{2+}\), Zn\(^{2+}\), and Ni\(^{2+}\) all induced significant levels of Arabidopsis MT2 gene expression; however, MT1 in Arabidopsis could not be induced by these ions except for Cu\(^{2+}\) in excised leaves (Zhou and Goldsbridge, 1994; Murphy and Taiz, 1995). Recently, expression of LSC54, a rape MT1 gene, was proven to be induced by ROS production and related to the misbalance of ROS during leaf senescence (Navabpour et al., 2003), and transgenic Arabidopsis plants overexpressing cgMT1 from beefwood (Casuarina glauca) reduced the accumulation of H\(_2\)O\(_2\) (Obertello et al., 2007). In addition, OsMT2b may also function as a ROS scavenger involved in the response to bacterial blight and blast fungus infections in rice (Wong et al., 2004).

In this study, a type 3 MT encoding cDNA, GhMT3a, was isolated from an NaCl-induced cotton cotyledon cDNA library. The up-regulation of GhMT3a expression was observed in cotton seedlings treated not only with high salinity but also with drought and low temperature (Fig. 3A, B, C). Interestingly, the levels of GhMT3a in cotton seedlings were also markedly increased by H\(_2\)O\(_2\) and PQ treatment (Fig. 4A). The induced expression of GhMT3a by these abiotic stresses could be completely inhibited in the presence of 1500 μM NAC, an antioxidant (Fig. 4B). Just as in the case of GhMT3a, NAC also decreased the levels of H\(_2\)O\(_2\) in cotton seedlings (Fig. 4C), indicating that there is a high correlation between the expression of GhMT3a and the misbalance of ROS production in cotton and GhMT3a may act as an antioxidant to minimize ROS toxicity, which was further confirmed by overexpressing GhMT3a in tobaccos and yeast. As shown in Figs 5 and 6, transgenic tobaccos displayed high tolerance against salt, drought, and low temperature stresses, and their H\(_2\)O\(_2\) levels were only half of that in WT plants. Transgenic yeast overexpressing GhMT3a showed more tolerance to ROS toxicity than the control. The purified GhMT1 protein from E. coli exhibited antioxidative capacity in vitro when no other metals and other antioxidants were applied. A number of studies have proved that the cysteine ligands in proteins are remarkably reactive towards oxidizing agents (Chae et al., 1994; Haslekas et al., 2003; Maret, 2004; Hao and Maret, 2006), including MTs (Zhou et al., 2002; Maret, 2004; Hao and Maret, 2006). Therefore, it could be concluded that GhMT1 acts as an endogenous antioxidant to respond to ROS stress in a direct manner.

It has been accepted that high levels of ROS lead to phytotoxicity, while relatively low levels can be signals inducing ROS scavengers and other protective mechanisms in plants (Couee et al., 2006; Gadjev et al., 2006; Miller et al., 2007). These results strongly support the idea that ROS signalling is indispensable for the regulation of GhMT3a expression during environmental stresses in plants. The fact that GhMT3a had antioxidant ability in vitro indicated the function of GhMT3a as a ROS scavenger (Fig. 6), revealing that plant metallothioneins play important roles as do their animal counterparts (Mattie and Freedman, 2004; Hao and Maret, 2006). Based on evidence that a number of transgenic plants or mutants with higher ROS scavenging ability showed increased tolerance to environmental stresses (Avsian-Kretchmer et al., 2004; Moradi and Ismail, 2007), it is proposed that the higher tolerance against abiotic stresses in transgenic tobaccos might be due to the scavenging of ROS production by the overexpression of GhMT3a. In addition, previous studies demonstrated that ROS may act as second messengers in redox signal transduction and are implicated in hormonal mediated events (Guan et al., 2000; Zhang et al., 2001). Thus, the ROS signal may also be the intermediate for the induced expression of GhMT3a by ABA and ethylene in our study.

Most previous research on plant MTs focus on heavy metal ions. The effects of metal ions on the expression of plant MT genes vary with plant species, tissues, and types of MT genes (Foley et al., 1997; Chang et al., 2004; Bellion et al., 2007). However, very little is known about the mechanism for the regulation of plant MT gene expression by metal ions. In this study, GhMT3a showed a high affinity to Zn\(^{2+}\) in vitro. The cysteine ligands in proteins are reactive towards oxidizing agents and release zinc (Maret, 2004; Hao and Maret, 2006). When released from MT, zinc may become available for the synthesis of antioxidant metal-binding proteins, such as Cu, Zn-superoxide dismutase, and at the same time be part of a mechanism that conducts spatial regulation of the oxidoreductive environment in the cell (Liochev and Fridovich, 2004). There is evidence that...
MTs release bound metals during oxidative stress and trigger a Zn-mediated antioxidant response in mammals and fungi (Maret, 1994; Tucker et al., 2004). The zinc-released MT can function as a reducing agent because of its high content of cysteines or rebind zinc under reducing conditions. Therefore, MTs may interact with other metal-proteins by releasing zinc within cells in response to spatial or temporary changes in the redox environment, which might be another function of MT in plant.

Taken together, the results indicate that the rapid accumulation of ROS in cotton plants after abiotic stresses (high salinity, drought, and low temperature) and the application of ABA or ethylene will induce the expression of GhMT3a. As a ROS scavenger, accumulation of GhMT3a during defence signalling would diminish ROS damage and then increase the tolerance of plants against abiotic stresses. Future studies are required to determine the relationship between GhMT3a and other antioxidant metalloproteins and whether the release of zinc ions from GhMT3a could be beneficial to the synthesis of other antioxidant metalloproteins or facilitate the activation of these proteins.
