Roots are the major organs for water and nutrient acquisition and substantially affect plant growth, development and reproduction. Improvements to root system architecture are highly important for the increased yield potential of bread wheat. QMrl-7B, a major stable quantitative trait locus (QTL) that controls maximum root length (MRL), essentially contributes to an improved root system in wheat. To further analyze the biological functions of QMrl-7B in root development, two sets of Triticum aestivum near-isogenic lines (NILs), one with superior QMrl-7B alleles from cultivar Kenong 9204 (KN9204) named NILKN9204 and another with inferior QMrl-7B alleles from cultivar Jing 411 (J411) named NILJ411, were subjected to transcriptomic analysis. Among all the mapped genes analyzed, 4871 genes were identified as being differentially expressed between the pairwise NILs under different nitrogen (N) conditions, with 3543 genes expressed under normal-nitrogen (NN) condition and 2689 genes expressed under low-nitrogen (LN) condition. These genes encode proteins that mainly include NO3− transporters, phytohormone signaling components and transcription factors (TFs), indicating the presence of a complex regulatory network involved in root determination. In addition, among the 13524 LN-induced differentially expressed genes (DEGs) detected in this study, 4308 and 2463 were specifically expressed in the NILKN9204 and NILJ411, respectively. These DEGs reflect different responses of the two sets of NILs to varying N supplies, which likely involve LN-induced root growth. These
Introduction

Crops produce a large proportion of food and nutrients for humans in modern society. During the past 50 years, the application of chemical fertilizers and the Green Revolution have substantially increased crop production, maintaining food security for the increasingly growing population (Godfray et al., 2010). However, a continuous increase in crop output cannot sustainably be achieved by excessive amounts of fertilizer because of the limited nutrient use efficiency (NUE) of crop plants. Importantly, a large amount of wasted resources and environmental pollution resulting from excessive fertilizer applications cannot be ignored (Springmann et al., 2018). For these reasons, crop cultivars that have relatively high NUE are environmentally friendly and helpful to conserve resources for sustainable agriculture. Roots, the major organs for plant anchorage, nutrient and water absorption, and interactions with symbiotic organisms, have attracted increased amounts of attention in recent studies given the discovery of their lack of aboveground visibility (Maqbool et al., 2022).

In general, manipulation of root architecture traits, including root number, root length, root surface area (RA) and root volume (RV), especially the spatial configuration of the root system in the soil, is an essential approach to increase crop yields, which may represent an important component of a new green revolution (Lynch, 2007; Meister et al., 2014). Unfortunately, root traits have been chronically overlooked in the traditional breeding due to their lack of aboveground visibility (Maqbool et al., 2022).

Bread wheat (Triticum aestivum L.) is one of the most important crop species worldwide, providing ~20% of calories for human needs (Appels et al., 2018). Efforts have been made to explore the determinants of root traits that contribute to increase yield potential in wheat. In addition to traditional labor-intensive and time-consuming methods for root trait analysis (Kücke et al., 1995), artificial medium systems, such as hydroponic culture, have been used in many studies and revealed a series of quantitative trait loci (QTLs) that drive genetic variation in root traits (An et al., 2006; Cao et al., 2014; Kabir et al., 2015; Maccarrelli et al., 2016; Merchuk-Ovnat et al., 2017; Fan et al., 2018; Zheng et al., 2019). However, it remains largely unclear of the mechanisms of these loci control root traits due to the complexity of the wheat genome. To date, a few genes regulating root morphology have been analyzed through reverse genetics studies in wheat. For example, the expressions of TaRSL2 (Han et al., 2017a) and TaLBD16 (Wang et al., 2018a) were shown to be positively correlated with root hair length and number of lateral roots, respectively. Heterogenous expressions of TaMPK4 (Hao et al., 2015) and TaMOR (Li et al., 2016) demonstrated their positive effects on root development. Overexpression of the transcription factor (TF)-encoding genes TaNAC2-5A (He et al., 2015), TaNFYA-B1 (Qu et al., 2015), TaNAC69-1 (Chen et al., 2016) and TaWRKY51 (Hu et al., 2018) resulted in enhanced root growth, while TabZIP60 (Yang et al., 2019) had the opposite effects, implying a complex genetic basis of the formation of root traits. In addition, circular RNAs have been shown to participate in root length regulation (Xu et al., 2019).

At present, a holistic view of the root growth regulatory network and how it affects root traits and yield potential is strongly needed for molecular breeding. RNA sequencing (RNA-seq) makes it possible to explore the consistency between root morphology and its underlying mechanisms at the whole-plant level through DEG analysis. For example, the transcriptomic analysis revealed how the root growth of salt-tolerant bermudagrass was maintained under salinity stress; the salt tolerance was attributed to appropriate expression levels of genes involved in reactive oxygen species (ROS) homeostasis and cell wall loosening, which were regulated in part by a number of TFs linked to stress responses and growth regulation (Hu et al., 2015). DEGs detected in maize cultured under different nitrogen (N) levels highlighted the network of root growth in response to N deficiency, where the LBD TF-encoding gene participated in the balance between nutrient metabolism and the stress response (He et al., 2016). RNA-seq data suggested crosstalk occurs among the roots (in terms of

Abbreviations: NN, normal-nitrogen; LN, low-nitrogen; NIL, near-isogenic line; DEG, differentially expressed gene; QTL, quantitative trait locus; RNA-seq, RNA sequencing; NUE, nitrogen use efficiency; MRL, maximum root length; TRL, total root length; RA, root surface area; RV, root volume; GO, Gene Ontology; KEGG, Kyoto Encyclopedia of Genes and Genomes.
growth promotion), gibberellin (GA) biosynthesis, auxin signaling, cell division and cell wall modification in uniconazole-treated soybean (Han et al., 2017b). These findings enriched our understanding of the molecular mechanisms behind the interplay of root traits and other agronomic characteristics, helping to generate strategies for crops with improved root systems, increased NUE and improved environmental adaptation.

Previous studies have shown that Triticum aestivum KN9204 has a larger root system than does cultivar J411 (Wang et al., 2011). Using a RIL population derived from the cross of KN9204 and J411 (KJ-RIL), researchers identified QMrl-7B as a major stable QTL that controls maximum root length (MRL) (Fan et al., 2018), and its contribution to large root systems was dissected (Liu et al., 2021), prompting the question of how QMrl-7B regulates root architecture and N uptake. In the present study, transcriptomic analysis of the pairwise QMrl-7B NILs was performed to further analyze the function of QMrl-7B in root development. The results will help reveal the pathways controlling root development that are affected by QMrl-7B in wheat, providing insights into the genetic and physiological basis underlying desirable root traits for agriculture.

Materials and methods

Plant materials and root phenotyping

KN9204 is a representative cultivar released in 2003 with a prolific root system, and J411 is a major cultivar that has been planted in the Northern China Plain since 1990s (Wang et al., 2011). Two sets of QMrl-7B NILs, one with superior alleles from KN9204 (referred to as the NILKN9204) and another with inferior alleles from J411 (referred to as the NILJ411) (Liu et al., 2021), were used in this study for transcriptomic analysis.

The root morphological traits of the pairwise QMrl-7B NILs were characterized in the experiments involving different N hydroponic cultures, with three replications. Seeds were imbibed in distilled water at 23°C for 24 h and then transferred to plastic pots containing moist vermiculite and nutrient-enriched soil (1:1, v/v) for ten days. Uniform seedlings (at the one- and half-leaf stages) were then chosen, after which their residual endosperm was removed; they were transferred to plastic pots containing moist vermiculite and imbibed in distilled water at 23°C for 24 h and then subsequently cultured in both normal-nitrogen (NN) and low-nitrogen (LN) nutrient solutions as described by Fan et al. (2018). On the fourteenth (four-leaf stage) and twenty-first (five-leaf stage) days in different N hydroponic cultures, five uniform seedlings of each NIL were evaluated for their average total root length (TRL, cm), maximum root length (MRL, cm), root area (RA, cm²) and root volume (RV, cm³). MRL was measured using a ruler, and the remaining traits (TRL, RA and RV) were quantified by using a ScanMaker i800 Plus Scanner (600 DPI) and analyzed by LA-S software (Hangzhou Wanshen Detection Technology Co., Ltd., Hangzhou, China; https://www.wseen.com).

Moreover, the roots of the four-leaf-stage seedlings of the pairwise NILs were sampled and immediately frozen in liquid N for subsequent RNA extraction. The root samples were divided into four treatments: the NILKN9204 under NN condition (NN_NILKN9204), the NILJ411 under NN condition (NN_NILJ411), the NILKN9204 under LN condition (LN_NILKN9204) and the NILJ411 under LN condition (LN_NILJ411). Each sample pool comprised five individual seedlings, and all experiments were replicated three times.

Transcriptome analysis

RNA extraction and sequencing

Total RNA was extracted from the root samples using TRizol Reagent (Plant RNA Purification Reagent for plant tissue, Invitrogen, USA) according to the manufacturer’s instructions, and genomic DNA was removed using DNase I (TaKaRa, Beijing, China). The quantity, quality, and integrity of the extracted RNA were determined using an ND-2000 spectrophotometer (Thermo Fisher Scientific, MA, USA) and an Agilent 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA, USA). Only high-quality RNA samples (OD260/280 = 1.8–2.2, OD260/230 ≥ 2.0, RNA integrity number (RIN) ≥ 6.5, 28S:18S ≥ 1.0, RNA content > 1 μg) were used to construct a sequencing library. Messenger RNA (mRNA) was isolated from the total RNA using magnetic beads with oligo (dT) primers and then cut into short fragments in a fragmentation buffer. Complementary DNA (cDNA) was subsequently synthesized using a SuperScript Double-Stranded cDNA Synthesis Kit (Invitrogen, CA, USA), with random hexamer primers (Illumina). The synthesized cDNA was then subjected to end repair, phosphorylation and polyadenylation according to Illumina’s library construction protocol. The libraries were size selected for cDNA target fragments of 300 bp on 2% low-range agarose followed by PCR amplification using Phusion DNA polymerase (NEB); fifteen PCR cycles were performed. After quantification by a TBS-380 fluorometer, the paired-end RNA-seq library was sequenced with an Illumina HiSeq Xten/ NovaSeq 6000 sequencer (2 × 150 bp read length). The library was then sequenced using the Illumina HiSeq™ platform (Shanghai Majorbio Bio-pharm Technology Co., Ltd., Shanghai, China).

Analysis of DEGs

The data were analyzed on the free online platform of the Majorbio Cloud Platform (https://www.majorbio.com). To obtain high-quality reads, reads containing adapter sequences and reads of low quality were removed from the raw data to obtain clean reads in FASTQ format. Q20 and Q30 values and GC contents were determined according to conventional
methods. Afterwards, the remaining clean reads were mapped to the reference genome of Chinese Spring (CS) (http://plants.ensembl.org/Triticum_aestivum/Info/Index/) by HISAT2 software (http://ccb.jhu.edu/software/hisat2/index.shtml). Unigene expression levels were estimated according to their transcripts per million reads mapped (TPM) values. DEGs between the NIL KN9204 and the NIL411 under both NN and LN conditions were then analyzed using the DESeq2 package (Love et al., 2014), and the expression results are presented in terms of the log2 fold change (FC). \(|\log_2 FC| \geq 1\) and \(p\)-adjusted < 0.05 were used as thresholds to judge the significance of gene expression differences. DEGs were also evaluated in response to LN stress for each NIL.

The DEGs of each one-to-one comparison were analyzed by Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis. GO functional enrichment and KEGG pathway analysis were carried out by GoTools (https://github.com/tanghaibo/GoTools) and KOBAS (http://kobas.cbi.pku.edu.cn/home.do), where GO terms and biological pathways with a \(p\)-adjusted < 0.05 were considered significantly enriched. The encoded products of the DEGs were subsequently annotated by the NCBI non-redundant protein (NR) database.

### Quantitative real-time polymerase chain reaction validation

To confirm the reliability of the DEGs obtained from RNA-seq, eight DEGs on chromosome 7B were selected for qRT-PCR analysis. Gene-specific primers were designed using Primer Premier 5.0 software (Premier Biosoft International); the sequences are shown in Table S1. qRT-PCR was carried out in total volumes of 20 μl using a SYBR PCR kit (TaKaRa, Beijing, China) on an ABI 7500 real-time PCR system (Applied Biosystems, MA, USA) according to the manufacturers’ instructions. Each sample was analyzed as three technical replicates, and the relative expression value of the DEGs was determined using the comparative cycle threshold (Ct) method after normalization to the expression of the GAPDH control.

### Results

#### Root traits of the pairwise NILs

The root traits of the seedlings in hydroponic cultures with different N contents were evaluated. On the fourteenth day after the seedlings were transferred to the nutrient solutions, the average MRL, TRL, RA and RV of the four-leaf-stage NIL KN9204 seedlings were 22.28 cm, 255.77 cm, 25.47 cm² and 0.25 cm³, respectively, under NN condition, which were significantly greater than those of the NIL411 (19.85 cm, 203.47 cm, 20.64 cm² and 0.20 cm³, respectively) under comparable conditions. Accordingly, the average MRL, TRL, RA and RV of the NIL KN9204 vs NIL411 at the seedling stage were 28.07 vs 21.54 cm, 301.75 vs 282.12 cm, 27.28 vs 24.90 cm² and 0.25 vs 0.21 cm³, respectively, under LN condition, indicating that the NIL KN9204 was superior to the NIL411 by 30.32%, 6.96%, 9.56% and 19.05%, respectively (\(p<0.05\)). Notably, the MRL of the NIL KN9204 seedlings under LN condition was 25.99% greater than that under NN conditions, while only an 8.51% difference was recorded for the NIL411 under the hydroponic cultures with different N contents, indicating that LN more strongly induced the growth of primary roots for the NIL KN9204 than for the NIL411 (Figure 1). Similar change trends of MRL, TRL, RA and RV differences in the five-leaf-stage seedlings were also observed between the two sets of NILs at twenty-one days after the 10-day-old seedlings were transferred to the nutrient solutions (Figure S1). Taken together, the above results showed that, in comparison to the NIL411, the NIL KN9204 had superior root architecture characteristics during the seedling stage, especially under LN condition.

#### Overview of transcriptome sequencing results

To explore the genetic and physiological basis of the superior root traits of the NIL KN9204, roots of four-leaf-stage seedlings of the pairwise NILs cultured under both NN conditions and LN conditions were sampled for transcriptomic analysis. RNA-seq on the Illumina HiSeq™ platform (http://www.majorbio.com) generated 70576620~90524786 clean reads per sample, with a sequencing error of less than 0.3%. The average Q20, Q30 and GC content percentages were 97.06%, 92.27% and 53.98%, respectively. These findings attest to the fine quality of the sequencing results. Mapping of the reads with the Chinese Spring (CS) reference genome revealed an alignment in a range of 81.48~90.35%, among which 76.14~84.54% of the genes were uniquely mapped and 5.34~6.28% were multiply mapped (Table S2). The correlation coefficient of repeats ranged from 0.69~0.98 (Figure S2, Table S3). These data were deemed suitable for subsequent analysis (Table S4), in which the DEGs whose expression was upregulated (\(\log_2 FC \geq 1\)) and downregulated (\(\log_2 FC \leq -1\)) in each one-to-one comparison were statistically (\(p\)-adjusted < 0.05) analyzed.

#### Identification of DEGs between the pairwise NILs

The transcriptomic changes in the roots between the pairwise QMrl-7B NILs were compared under both NN and LN conditions. Under NN condition, a total of 3543 genes were differentially expressed between the two sets of NILs, of which
the expression of 1045 genes was upregulated and that of 2498 was downregulated in the NIL KN9204 (Figure 2A; Table S5). These genes were enriched in 320 subcategories according to GO analysis, of which 200, fourteen and 106 belonged to biological processes, cellular components and molecular functions, respectively, and the three most enriched biological processes were "biological process (GO:0008150)", "metabolic process (GO:0008152)" and "phosphate-containing compound metabolic process (GO:0006796)" (Table S6). "Phenylpropanoid biosynthesis (map00940)" was the most enriched pathway according to KEGG analysis (Table S7). Under the LN condition, 2689 genes were differentially expressed between the pairwise NILs, including 990 genes whose expressions were upregulated and 1699 genes whose expressions were downregulated in the NIL KN9204 (Figure 2A; Table S8). These DEGs were categorized into biological process (141), cellular component (12) and molecular function (77) categories by GO analysis. The three most enriched biological processes were "biological process (GO:0008150)", "metabolic process (GO:0008152)" and "phosphate-containing compound metabolic process (GO:0006796)" (Table S9). Similarly, "phenylpropanoid biosynthesis (map00940)" was the most enriched pathway according to the KEGG analysis (Table S10).

Notably, there were 315 DEGs whose expressions increased and 1034 DEGs whose expressions decreased in the NIL KN9204 compared to the NIL J411 simultaneously under both NN and LN conditions (Figure 2A). These genes might participate in translation, transcriptional regulation and cycle control according to GO and KEGG enrichment analysis (Figure 2B; Tables S11-S13), reflecting the permanent effects of the QMrl-7B locus that were not affected by N levels. Under NN condition, nine genes were expressed at higher levels in the NIL KN9204 than in the NIL J411; however, these genes were expressed at a higher level in the NIL J411 under LN condition (Figure 2A; Table 1). In addition, three genes exhibited the opposite expression trend, implying their functional difference in response to N stress (Figure 2A; Table 1).

Identification of DEGs in response to N deficiency

The differences in DEGs in the root response to N deficiency between the NIL KN9204 and NIL J411 were analyzed. Compared with the NN condition, LN condition yielded 11073 DEGs (6341 whose expression increased and 4732 whose expression decreased) and 9228 DEGs (5072 whose expression increased and 4156 whose expression decreased) in the NIL KN9204 and NIL J411, respectively (Figure 3A). A total of 2385 DEGs whose expressions increased and 1923 DEGs whose expressions decreased were detected only in the NIL KN9204 (Figure 3A; Table S14), whereas 1116 DEGs whose expressions increased and 1347 DEGs whose expressions decreased were detected specifically in the NIL J411 (Figure 3A; Table S17). Interestingly, there were more genes whose expressions were upregulated than genes whose expressions were downregulated in the NIL KN9204, and the opposite trend occurred in the NIL J411. GO analysis showed that these DEGs participate in multiple processes, and "phenylpropanoid biosynthesis (map00940)" was the most enriched process according to KEGG analysis (Figures 3B, C; Table 1).
The expression of genes that differed specifically in the NILKN9204 or the NILJ411 might give rise to a specific N response related to QMrl-7B, while a large number of common DEGs (3956 genes whose expression was upregulated and 2809 genes whose expression downregulated) in the two sets of NILs reflected the general response to N stress in wheat.

**Quantitative real-time PCR verification**

qRT-PCR analysis revealed that the expression levels of eight randomly selected DEGs on chromosome 7B were significantly different between the NILKN9204 and the NILJ411 under NN conditions and LN conditions (Figure 4). These results nearly matched the expression profiles revealed by RNA-seq, confirming the results of the transcriptome sequencing of the pairwise NILs cultured under both NN and LN conditions.

**Discussion**

Improving plant roots is an effective way to increase NUE and minimize fertilizer application for sustainable agricultural development (Lynch, 2007). A number of genes/QTLs have been
reported to be related to root growth and development; as such, these genes/QTLs have potential application in crop genetic improvement (Zhuang et al., 2021; Chen et al., 2022; Li et al., 2022). However, the genetic network explaining how these genes interact to influence root architecture still needs to be elucidated to access the beneficial agronomic traits from an overall perspective and to guide the use of beneficial genes or pyramid of allelic variation in future breeding efforts. Compared with J411, KN9204 had a larger root system (Wang et al., 2011), with the stable QTL QMrl-7B was associated (Fan et al., 2018). Further studies involving QMrl-7B NILs showed that, as compare to the NILJ411s, the NIL\textsuperscript{KN9204}s had superior root traits, N-related traits and yield traits in the NILKN9204, and genes with log\textsubscript{2}FC ≥ 1 (p-adjusted< 0.05, coloured red) represent the genes whose expression was downregulated in the NIL\textsuperscript{KN9204}, and genes with log\textsubscript{2}FC ≤ -1 (p-adjusted< 0.05, coloured blue) represent the genes whose expression was upregulated in the NIL\textsuperscript{KN9204}.

NN and LN indicate normal- and low-nitrogen conditions, respectively. AA and BB indicate the NILKN9204 and the NILJ411, respectively. The expression levels between the NIL\textsuperscript{KN9204} and the NIL\textsuperscript{J411} were compared under each condition, with the latter as a control. The expression ratios are presented as log\textsubscript{2}FC values. Genes with a log\textsubscript{2}FC ≥ 1 (p-adjusted< 0.05, coloured red) represent the genes whose expression was upregulated in the NIL\textsuperscript{KN9204}, and genes with log\textsubscript{2}FC ≤ -1 (p-adjusted< 0.05, coloured blue) represent the genes whose expression was downregulated in the NIL\textsuperscript{KN9204}.
Identification of DEGs induced by LN NN and LN indicate normal- and low-nitrogen conditions, respectively. Spe indicates DEGs specifically expressed in the NIL kn9204 or the NIL kn441. The expression levels between NN and LN conditions were compared for each NIL, with NIL kn9204 as a control. LN vs NN_Up and LN vs NN_Down indicate DEGs whose expression was upregulated and downregulated under LN compared to NN for the same NIL. (A) Venn diagram analysis of the DEGs in each one-to-one comparison between NN and LN conditions for both the NIL kn9204 and NIL kn441. (B, C) GO annotation analysis of the genes whose expression differed specifically in the NIL kn9204 (B) and NIL kn441 (C) with the first 20 terms as indicated.

FIGURE 3

Similarly, two high-affinity NRT genes (TraesCS6B02G044300 and TraesCS6D02G035900) exhibited lower expression levels in the NIL411 under NN condition, but higher expression levels in the NIL411 than in the NILKN9204 under LN condition (Table 1). In addition, the expressions of four high-affinity NRT genes (TraesCS6A02G031000, TraesCS6A02G031100, TraesCS6B02G044100 and TraesCS6B02G044500) were induced specifically by LN in the NIL411 but not in the NILKN9204 (Table 2). Our present study showed that LN led to altered expression of a number of genes encoding both low-affinity and high-affinity NRTs (Table S4), in accordance with the viewpoint that different NRTs function at different N levels (Zhang and Forde, 1998).

Dual-affinity nitrate transporter 1 (NRT1) not only functions in N acquisition but also is a NO\textsuperscript{3−} sensor; this action is independent of its uptake activity that controls root development (Ho et al., 2009). The cotransport of NO\textsuperscript{3−}, peptides and hormones through the NRT1 family of transporters implies the occurrence of crosstalk between NO\textsuperscript{3−} and other signaling pathways (Krouk et al., 2010; Tal et al., 2016). In our study, the expression levels of two and eleven putative NRT1 genes in the NILKN9204 were higher and lower than those in the NIL411 under both NN and LN conditions (Table 3), respectively, indicating that the differences in root traits may result mainly from NRT1 functional differentiation. Additionally, the higher expression level of the CBL-interacting protein kinase 23 (CIPK23) gene (TraesCS2A02G251800) in the NIL411 compared to the NILKN9204 was also independent of N status (Tables S5 and S8); this phenomenon may affect root formation together with NRT1 by phosphorylating T101 to regulate its primary NO\textsuperscript{3−} response and high-affinity NO\textsuperscript{3−} transport (Ho et al., 2009). Taken together, these results implied that a more sensitive response of roots to N acquisition occurred in the NIL411 compared with the NILKN9204, which cannot be fully explained.

Phytohormones, together with their receptors and signaling components, constitute the main intrinsic regulatory pathways of root traits. Ethylene, whose biosynthesis is regulated by several key enzymes, such as 1-aminocyclopropane-1-carboxylic acid (ACC) synthase (ACS) and ACC oxidase (ACO), usually plays a negative regulatory role in root growth, inhibiting root enlargement and root meristem cell proliferation (Pattyn et al., 2020). In addition, ethylene regulates the expression of glutathione S-transferase (GST)-encoding genes. GST catalyses the conjugation of glutathione to various electrophilic compounds involved in the oxidative stress response, crosstalk with other hormones and drought-induced root growth (Dalal et al., 2018). Under both NN and LN conditions, significant increases in expression levels of genes encoding ACOs and GSTs were detected in the NIL411, with parallel increases in expression levels of genes encoding ethylene-responsive TFs (Table 4), implying that enhanced ethylene signaling together with glutathione metabolism negatively regulated root growth in the NIL411. GA, whose catabolism is catalysed by GA2-oxidase, is considered a negative regulator of lateral root formation (Gou et al., 2010). However, overexpression of GA2-oxidase-encoding genes led to shortened primary root length, and mutations in these kinds of genes led to somewhat longer roots (Li et al., 2017), indicating a negative correlation between GA2-oxidase-encoding genes and root length. Compared to the NILKN9204, the NIL411 displayed upregulated expression levels of several GA2-oxidase-encoding genes under both NN and LN conditions (Table 4); these upregulated levels may have inhibitory effects on root development. Brassinosteroids (BRs) regulate both root meristem size and cell expansion in controlling root growth.

NN and LN indicate normal- and low-nitrogen conditions, respectively. A and B indicate the NILKN9204 and the NILJ411, respectively. The expression levels between the NILKN9204 and the NILJ411 were compared under each condition, with the latter as a control. The expression ratios are presented as log2FC values. Genes with log2FC ≥ 1 (p-adjusted < 0.05, coloured red) represent the genes whose expression was downregulated under LN conditions, and genes with log2FC ≤ 1 (p-adjusted ≤ 0.05, coloured blue) represent the genes whose expression was upregulated under LN conditions.

Deficiency or insensitivity of BRs leads to reduced root growth and lateral root formation (Wei and Li, 2016). The decreased expression of receptor-like protein kinase BRII-like 3 genes in the NILJ411 might impair BR signaling and inhibited root enlargement (Table 4). Auxin facilitates lateral root initiation and development (Fukaki and Tasaka, 2009), while cytokinin antagonistically negatively regulates root growth (Moubayidin et al., 2009). In rice, crown root primordium initiation was promoted by auxin signaling, whereas cytokinin signaling inhibited it (Neogy et al., 2021). Members of the GH3 gene family respond to auxin and their encoding products use various amino acids as substrates to form indole-acetic acid (IAA)-amido conjugates for temporary storage and degradation (Staswick et al., 2005). Arabidopsis GH3.17 gene regulates environment-induced hypocotyl elongation (Zheng et al., 2016) and it is also responsible for root elongation, whereas gh3 mutants accumulate more free-IAA at the expense of any IAA-Glu and IAA-Asp auxin conjugates which causes defects in root development, demonstrating the critical roles of GH3 genes in auxin homeostasis and plant development (Guo et al., 2022). Cytokinin is activated by phosphoribohydrolase, which catalyses the hydrolysis of the bond between N6-substituted bases and ribose 5’-monophosphates in cytokinin precursors during its biosynthesis process (Kurakawa et al., 2007). Rice GH3-8 gene functions as a repressor of auxin-dependent developmental signaling, overexpression of GH3-8 suppressed auxin action, which resulted in abnormal morphology similar to that reported in auxin-deficient plants i.e. shorter roots and fewer adventitious roots (Ding et al., 2008). Significant increases in expression levels were observed for genes encoding GH3.8 and phosphoribohydrolase in the NILJ411, accompanied by decreased expression levels of a gene encoding an auxin-responsive protein (Table 4), implying the presence of weakened auxin signaling and accelerated cytokinin flux in the NILJ411, which may be related to the differences in root traits of the pairwise NILs.

Several types of TFs play essential roles in root growth by regulating the expression of downstream genes that are usually closely associated with nutrient acquisition. Overexpression of TaNFYA-B1 was shown to increase both primary root length and total lateral root length in wheat (Qu et al., 2015). The expression levels of genes encoding NF-Y subunit C-3-like proteins (TraesCS1A02G354900, TraesCS1B02G366800 and TraesCS1D02G355600) were higher in the NILKN9204 than in the NILJ411 under LN condition (Table 5), indicating their potential contribution to LN-induced root enlargement. NAC
### Table 3: Differentially expressed NRT genes between the pairwise NILs.

(Continued)
TFs function in response to NO$_3^-$, depending on the NRT1.1 N O$_3^-$ transport function (Vidal et al., 2014), to increase root biomass (He et al., 2015). Two genes encoding NAC TFs (TraesCS3A02G078400 and TraesCS3D02G078900) exhibited higher expression levels in the NIL$_{KN9204}$ than in the NIL$_{1441}$ under both NN and LN conditions (Table 5), implying that they had similar effects on root growth. Ethylene responsive factors (ERFs) belong to the AP2/ERF (APETALA2/ERF) superfamily of transcription factors associated with various developmental processes and stress tolerance. It was reported that ERF transcription factor gene TaSRL1 resulted in short root length when ectopically expressed in rice (Zhuang et al., 2021). In the present study, expressions of ERF-like genes were significantly down-regulated in the NIL$_{KN9204}$ compared to the NIL$_{1441}$ under both NN and LN conditions, which may contribute to longer root length in NIL$_{KN9204}$.

In conclusion, transcriptomic analysis in the present study revealed the landscape of the DEGs between the QMrl-7B NILs under both NN and LN conditions, reflecting the physiological basis of the large roots of the superior parent KN9204. This study used pairwise NILs for analysis to dampen the effects from different genetic backgrounds; as such, the DEGs are more likely to be related to QMrl-7B, either directly or indirectly. These results revealed many pathways regulated by genes that might interact genetically with QMrl-7B, which may provide a foundation for the application of QMrl-7B in molecular breeding. However, since the materials used for RNA-seq were seedlings and not mature plants, much work is still needed to elucidate the overall genetic network that controls ideal root traits of wheat plants at different stages.

**Data availability statement**

The data presented in the study are deposited in the NCBI repository, accession number PRJNA889686. The accession number PRJNA889686 (http://www.ncbi.nlm.nih.gov/bioproject/889686).
Author contributions
LS, JYL, LZ, NZ, WZ, DM, XR, JJ and JML conducted the hydroponic culture and field experiments. LS, JYL, LZ and AB analyzed the data. LS, JYL, YN and AB wrote the manuscript. RL and JML revised the manuscript. All authors contributed to the article and approved the submitted version.

Funding
This research was jointly supported by grants from the National Key Research and Development Program of China (2021YFF1000403), the National Natural Science Foundation of China (U22A6009), Hebei Natural Science Foundation (C2021205013) and China Agriculture Research System of MOF and MARA (CARS-03).

Acknowledgments
We are very grateful to Dr. Xigang Liu from Hebei Normal University, Shijiazhuang, China for his critical review of the manuscript.
