Abstract. Using an effective Lagrangian approach as well as the Quark-Gluon Strings Model we analyze near-threshold production of $a_0(980)$-mesons in the reaction $NN \rightarrow dK\bar{K}$ as well as the background of non-resonant $K\bar{K}$-pair production. We argue that the reaction $pp \rightarrow dK^+\bar{K}^0$ at an energy release $Q \leq 100$ MeV is dominated by the intermediate production of the $a_0(980)$-resonance. At larger energies the non-resonant $K^+\bar{K}^0$-pair production — where the kaons are produced in a relative $P$-wave — becomes important. The effects of final-state interactions are evaluated in a unitarized scattering-length approach and found to be in the order of a 20% suppression close to threshold. Thus in present experiments at the Cooler Synchrotron COSY-Jülich for $Q \leq 107$ MeV the $a_0^0$ signal can reliably be separated from the non-resonant $K^+\bar{K}^0$ background.

PACS. 25.10.+s Meson production – 13.75.-n Proton induced reactions

1 Introduction

During the last two decades the physics of the lightest scalar mesons $a_0(980)$ and $f_0(980)$ has gained vivid attention. The constituent quark model considers these scalar mesons as conventional $q\bar{q}$ states (see, e.g., Refs. \cite{12,14,15,16} and references therein), however, the structure of these states seems to be more subtle. Alternative descriptions are $K\bar{K}$ molecules \cite{6,7,8,13}, unitarized $q\bar{q}$ states \cite{9,10} or four-quark cryptoexotic states \cite{11,12,13}. A further problem with these light scalar mesons is a possibly strong mixing between the uncharged $a_0(980)$ and the $f_0(980)$ due to a common coupling to $K\bar{K}$ intermediate states \cite{12,14,15,16}. This effect will influence the structure of the uncharged component of the $a_0(980)$ and implies that a comparative study of the $a_0^0$ and $a_0^+$ (or $a_0^\pm$) has to be performed. Moreover, the $a_0(980)$-$f_0(980)$ mixing can generate isospin violation in different reactions with $a_0/f_0$ production \cite{17,18,19,20}.

At COSY-Jülich an experimental program on the study of near-threshold $a_0/f_0$ production in $pp$, $pn$, $pd$ and $dd$ interactions has been started with the ANKE spectrometer \cite{21,22,23,24,25}. Recently, first results on the reaction $pp \rightarrow dK^+\bar{K}^0$ near threshold have become available at an excess energy of $Q = 46$ MeV \cite{26}. The present study is devoted to the theoretical analysis of these data. Furthermore, we provide predictions for different observables at larger excess energy $Q$ and investigate the influence of final-state interactions (FSI), the importance of which has been pointed out in Ref. \cite{27}.

In a recent work \cite{29} we have considered $a_0$ production in the reactions $\pi N \rightarrow a_0 N$ and $NN \rightarrow d a_0$ near threshold and at beam energies up to a few GeV. An effective Lagrangian approach as well as the Regge-pole model were applied to investigate different contributions to the cross section of the reaction $\pi N \rightarrow a_0 N$. These results were also used for an analysis of $a_0$ production in $NN$ collisions \cite{29,30}. In this paper we present a more detailed study of the reaction $NN \rightarrow dK\bar{K}$ taking into account both the $a_0$ contribution to this reaction as well as the non-resonant $K\bar{K}$ background. We demonstrate that the $u$-channel mechanism — normalised to the data from LBL (Berkeley) for the reaction $pp \rightarrow dX$ at 3.8 GeV/c \cite{31} — can reproduce the total cross section of the reaction $pp \rightarrow d a_0^+ \rightarrow dK^+\bar{K}^0$ at 3.46 GeV/c ($Q = 46$ MeV) as measured at ANKE. However, it fails to reproduce the distribution in the deuteron scattering angle. We show that quantitatively better results can be achieved within the framework of the Quark-Gluon Strings Model (QGSM).

Our paper is organized as follows: In Sect. 2 and 3 the two-step model within the framework of an effective Lagrangian approach is used for the analysis of different contributions for resonant (through the $a_0$) and non-resonant production of $K\bar{K}$ pairs in the reaction $NN \rightarrow dK\bar{K}$. In Sect. 4 the reaction $NN \rightarrow d a_0 \rightarrow dK\bar{K}$ is considered additionally within the Quark-Gluon Strings Model while in Sect. 5 a detailed analysis of final-state interactions (FSI) is given. Our conclusions are presented in Sect. 6. The amplitudes for the different contributions to the reactions $\pi N \rightarrow a_0 N$ are given in the Appendix.
2 Effective Lagrangian approach to the reaction $NN \rightarrow dK\bar{K}$

Within the framework of the two-step model (TSM) with one-pion exchange in the intermediate state (cf. Refs. [32,33]) the contributions of hadronic intermediate states to the amplitude of the reaction $pp \rightarrow da^+_0 \rightarrow dK^+\bar{K}^0$ are described by diagrams $a)$ -- $c)$ in Fig. 1. Accordingly, we consider different contributions to the resonant amplitude $\pi N \rightarrow a_0 N \rightarrow K\bar{K}N$: i) the $u$- and $s$-channel nucleon exchanges (Fig. 1a) and b), respectively; ii) the $\eta$- and $f_1(1285)$-meson exchanges (Fig. 1c); iii) the $b_1$ and $p_2$ Reggeon exchanges (Fig. 1c).

The non-resonant background contribution to the reaction $NN \rightarrow dK\bar{K}$ is described by the diagrams in Fig. 2a) and b) for $\pi \rightarrow K^+ \rightarrow \eta(\pi)$- and $K$-exchange, respectively (see also Ref. [34]).

Since we are interested in the $pp \rightarrow da^+_0$ and $pp \rightarrow dK^+\bar{K}^0$ cross sections near threshold, where the momentum of the final deuteron is comparatively small, we use a non-relativistic description of this particle by neglecting the 4th component of its polarization vector. Correspondingly, the relative motion of the nucleons in the deuteron is also treated non-relativistically. The $pp \rightarrow da^+_0$ and $pp \rightarrow dK^+\bar{K}^0$ amplitudes have to be antisymmetrized with respect to permutation of the initial protons $a$ and $b$ respectively and can be written as:

$$T_{pp \rightarrow da^+_0}(p_a, q_d) = T^{ab}_{pp \rightarrow da^+_0}(p_a, q_d)$$

$$T_{pp \rightarrow dK^+\bar{K}^0}(p_a, q_d) = T^{ab}_{pp \rightarrow dK^+\bar{K}^0}(p_a, q_d)$$

Here and below the notations $q_1, q_2, q_d, p_a$ and $p_b$ are used for the 4-momenta of the $\bar{K}^0$, $K^+$, deuteron, initial protons $a$ and $b$, respectively. We have introduced the relative 3-momenta $q_{12} = (q_1 - q_2)/2$ for the final kaons, which are also considered as nonrelativistic particles for excess energies $Q \leq 100 \div 150$ MeV. The motion of the nucleons $a'$ and $b'$ in the deuteron is described by the relative momentum $p_{a'b'} \equiv (p_{a'} - p_{a'})/2 = p_{a'} - q_d/2$. Then one can write the first terms $T^{ab}_{pp \rightarrow da^+_0}(p_a, q_d)$ and $T^{ab}_{pp \rightarrow dK^+\bar{K}^0}(p_a, q_d)$ on the r.h.s. of Eqs. (1) and (2) as follows:

$$T^{ab}_{pp \rightarrow da^+_0}(p_a, q_d) = f_{\pi NN}/m_{\pi} (p_0 + m_N) (2m_N)^{3/2}$$

$$\times \sum_{X(a_0)} M_{pp \rightarrow da^+_0}^{(X(a_0))j}(p_a, q_d) \psi^T_{X}(p_a)$$

$$\times (-i\sigma_2)^{j} \varepsilon^*(d)\varphi_{X}(p_b),$$

$$T^{ab}_{pp \rightarrow dK^+\bar{K}^0}(p_a, q_d)$$

FIG. 2. Diagrams describing non-resonant mechanisms in the reaction $pp \rightarrow dK^+\bar{K}^0$ within the framework of the two-step model.
$T_{pp \to dK^0}^{ab}(p_a, q_d, q_{12}) = \int d^4p_{b' a'} \frac{f_{\pi NN}}{m_\pi} (p_0^2 + m_N) (2m_N)^{3/2}$

$\times \left\{ -\frac{p_a^0}{p^0 + m_N} + \frac{(-2p_{b'a'} + q_d^0)}{4m_N} \right\}$

$\times \left( -(i\sigma_2) \sigma \cdot e^{(d)} \sigma^I_{\alpha} \right) (p_b) \right) \right.$

$\Psi_{d}(p_{b'a'})$ is the deuteron wave function, $t_{aa'} = (p_a - p_{a'}^2)^2$ is the virtual pion momentum squared. The vector functions

$g_{\pi NN \to a_0 N}(p_a, q_d, q_{12}) = \int d^4p_{b' a'} \frac{F_{\pi NN}(t_{aa'})}{t_{aa'} - m_\pi^2}$

$\times \left\{ -\frac{p_b^0}{p^0 + m_N} + \frac{(-2p_{b'a'} + q_d^0)}{4m_N} \right\}$

$\times \left( -(i\sigma_2) \sigma \cdot e^{(d)} \sigma^I_{\alpha} \right) (p_b) \right) \right.$

The amplitudes for different mechanisms of the $\pi^- p \to a_0 N$ reaction as follows

$M_{\lambda_{\pi}\lambda_{b'}}(\pi^- p \to a_0 N) = \sum_{j=0}^{1} \left\{ -\frac{p_b^0}{p^0 + m_N} + \frac{(-2p_{b'a'} + q_d^0)}{4m_N} \right\}$

$\times \left( -(i\sigma_2) \sigma \cdot e^{(d)} \sigma^I_{\alpha} \right) (p_b) \right) \right.$

The non-resonant $K^+ K^-$ production via $K^* - P$ exchange with a pseudoscalar meson $P = \pi^0$ or $\eta$ is given by

$g_{\pi K^+ K^-}(p_a, q_d, q_{12}) = \frac{F_{\pi NN}(t_{bb'})}{t_{bb'} - m_\pi^2}$

$\times \left\{ -\frac{p_b^0}{p^0 + m_N} + \frac{(-2p_{b'a'} + q_d^0)}{4m_N} \right\}$

$\times \left( -(i\sigma_2) \sigma \cdot e^{(d)} \sigma^I_{\alpha} \right) (p_b) \right) \right.$

where the elementary $\pi^- P \to K^+ K^-$ transition amplitude has the form

$T_{\pi^- P \to K^+ K^-} = \frac{g_{\pi K^+ K^-} - g_{\pi K^+ K^-}}{\sqrt{2}}$

$\times \left\{ (p_a - p_{a'} + q_1)_{\mu} (p_b - p_{b'} + q_2)_{\nu} \left( \frac{t_{aa'} - m_N^2}{t_{bb'} - m_K^2} \right) \right\}$

$\times \left( -(i\sigma_2) \sigma \cdot e^{(d)} \sigma^I_{\alpha} \right) (p_b) \right) \right.$

$\times \left( -(i\sigma_2) \sigma \cdot e^{(d)} \sigma^I_{\alpha} \right) (p_b) \right) \right.$

$\times \left( -(i\sigma_2) \sigma \cdot e^{(d)} \sigma^I_{\alpha} \right) (p_b) \right) \right.$
Here \( t_{K^*} = (p_a - p_b - p_{a'} + p_{b'})^2 \). The coupling constants \( g_{K^*\pi K} = -3.02, g_{K^*\eta K} = \sqrt{3} g_{K^*\pi K} \) and the cut-off parameter for the virtual \( K^* \) exchange \( \Lambda_{K^*} (K^*\eta K) = 3.29 \) GeV are taken from Ref. [27]. The remaining cut-off parameter \( \Lambda_{K^*} (K^*\pi K) \) is adjusted to reproduce the experimental data \[ \text{(see Sect. 3).} \]

The non-resonant \( K^* \) exchange part of the corresponding amplitude reads

\[
A_{\text{non-res}} = \text{const} \cdot \frac{1}{t_{K^*}} \text{with } t_{K^*} = (p_a - p_b - p_{a'} + p_{b'})^2.
\]

This rule follows from \( G \)-parity conservation. We recall that the \( G \)-parity of the \( K \bar{K} \)-system with orbital momentum \( L \) and isospin \( I \) is given by \((-1)^{L+I}\). Therefore, for \( I = 1 \) in our case the orbital momentum of the \( K \bar{K} \)-pair should be odd for positive \( G \)-parity and even for negative \( G \)-parity. Thus the non-resonant \( S-, D- \ldots \) wave \( K \bar{K} \)-pair production in the \( pp \rightarrow dK^+\bar{K}^0 \) reaction is contributed by the \( \pi - K^* - \eta \) exchange mechanism (see also Sect. 3). We note that the amplitude (15) takes into account only the \( K^* \) exchange.

For the sake of completeness we have calculated also the \( K \)-exchange term defined by the diagram of (Fig. 3c). The corresponding amplitude reads

\[
T^{(K)ab}_{pp \rightarrow dK^+\bar{K}^0} (p_a, q_d, q_{12}) = \frac{1}{\sqrt{2m_N}} \times (16)
\]

\[
M^{(K)}_{pp \rightarrow dK^+\bar{K}^0} (p_a, q_d, q_{12}) \varphi_{\lambda_a}^T (p_a) (-i\sigma_2) \chi \cdot e^{i(d)} \varphi_{\lambda_b} (p_b),
\]

with the scalar function

\[
M^{(K)}_{pp \rightarrow dK^+\bar{K}^0} (p_a, q_d, q_{12}) = \int \frac{d^3p_{a'}}{(2\pi)^3/2} \Psi_d(p_{a'})
\times A_{KN \rightarrow K\bar{N}} (p_a, q_d, q_{12}) A_{\bar{K}\bar{N} \rightarrow K\bar{N}} (p_a, q_d, q_{12})
\times \frac{F_{dN}^2(K)}{t_{K^*} - m_N^2}.
\]

Here \( t_{K^*} \) is the squared 4-momentum of the virtual kaon. For the \( K\bar{N}(\bar{K}\bar{N}) \) cross sections we used the parametrizations from Ref. [55]. The cut-off parameter \( \Lambda_{K} \) was taken to be 1.2 GeV (see, e.g. Ref. [56].)

Keeping in mind that the nucleons in the deuteron are considered as nonrelativistic particles, the momentum transfers squared in the denominators of the propagators in Eqs. (5-9) can be rewritten as follows

\[
t_{aa'} \simeq -2 \frac{1}{m_N} \left( p - m_N \right) \left( p - m_N \right) - \frac{1}{2m_N} \left( p_{a'} + q_d \right)^2
\]

\[
-2 \frac{p_a \cdot p_{a'}}{m_N} + \frac{1}{m_N} \left( p - q_{12} \right)^2,
\]

\[
t_{bb'} \simeq -2 \frac{1}{m_N} \left( p - m_N \right) \left( p - m_N \right) - \frac{1}{2m_N} \left( p_{b'} + q_d \right)^2
\]

\[
-2 \frac{p_b \cdot p_{b'}}{m_N} + \frac{1}{m_N} \left( p - q_{12} \right)^2,
\]

\[
t_{KK^*} \simeq t_{K^*} \simeq - \left( p_a + p_{b'} - q_{12} \right)^2.
\]

The structure of the amplitudes 1 and 2 guarantees that their \( S \)-wave parts (when the initial and final states have orbital momenta equal to zero) vanish since they are forbidden by angular momentum conservation and the Pauli principle. The second terms \( T^{ba}_{pp \rightarrow dN^+K^0} (p_b, q_d) \) and \( T^{ba}_{pp \rightarrow dK^+\bar{K}^0} (p_b, q_d, q_{12}) \) on the r.h.s. of Eqs. 1 and 2 can be obtained from the first

3 \( a_0 \) cross section and non-resonant background in the reaction \( pp \rightarrow dK^+\bar{K}^0 \)

3.1 \( a_0 \)-resonance contribution

To illustrate the hierarchy of the different mechanisms in the case of \( a_0 \) production we present in Fig. 3 our results for the total cross section of the reaction \( pp \rightarrow da^+_0 \). As in Ref. [28] the \( a_0 \) coupling constant was taken from the Bonn model [57]. For the virtual nucleon we used the standard form factor given by Eq. (41) in the Appendix with a cut-off parameter \( \Lambda_N = 1.3 \) GeV, which satisfies the constraints found in our recent analysis of the \( \pi N \rightarrow N \bar{K}K \) and \( NN \rightarrow N N \bar{K}K \) reactions [60] (see comment after Eq. (41)). Moreover, using this approach we can simultaneously describe the LBL data on the forward differential cross section of the reaction \( pp \rightarrow da^+_0 \) at 3.8 GeV/c [61]. In practical terms: the cut-off parameter \( \Lambda_N \) may also be defined by normalizing the \( u \)-channel contribution to the LBL data.

The parameters of the Regge model have been fixed by Achasov and Shrestakov [14] in fitting Brookhaven data on the reaction \( \pi^- p \rightarrow a^0_0 n \) at 19 GeV/c [62]. All other parameters were taken the same as in Ref. [60] (see also Appendix).
As seen in Fig. 3, the dominant contribution to the cross section of the reaction $pp \to d\bar{a}_0^+K^0$ near threshold comes from the $u$-channel mechanism (shown by the bold dashed line) and all other contributions from $f_1$ and $\eta$-meson exchanges, $s$-channel nucleon exchange and $b_1$- and $\rho_2$-Reggeons can be neglected (for the forward differential cross section this result was obtained earlier in Ref. [28]).

The $a_0$-resonance contribution to the cross section of the reaction $pp \to d\bar{a}_0^+K^0$ is calculated by convoluting the cross section of the $a_0^+$ production with the Flatté mass distribution (see Eq. (8) and also Ref. [30]). The result for the dominant $a_0$-resonance part corresponding to the diagram in Fig. 2(a) is shown by the long-dashed line in Fig. 4. The parameters of the Flatté mass distribution are taken from Ref. [34]; $m_0 = 999$ MeV, $g_{\pi\eta} = 324$ MeV and $g_{\bar{K}K}/g_{\eta\eta} = 1.03$. As it follows from Fig. 3 the total cross section of the reaction $pp \to d\bar{a}_0^+$ at $p_{lab} = 3.46$ GeV ($Q = 46$ MeV) in the narrow $a_0$ width limit is about 1.2 $\mu$b. After convolution with the Flatté distribution we find that $\sigma(pp \to d\bar{a}_0^+ \to K^+K^0)$ is about 28 nb (see Fig. 4). The effective branching ratio for the $a_0$ decay to the $K\bar{K}$ mode is 0.023 at $Q = 46$ MeV. Such a large suppression as compared with the standard value $\Gamma_{K\bar{K}}/\Gamma_{\pi\eta} = 0.177 \pm 0.024$ [29] is related to the phase space limitation and the $P$-wave character of $a_0$ production in the reaction $pp \to d\bar{a}_0^+$ near threshold.

3.2 Background contributions

An important problem is to understand the role of the non-resonant contribution to the $pp \to dK^+\bar{K}^0$ cross section. In Ref. [30] the $\pi - K^* - \pi(\eta)$-exchange mechanisms for non-resonant $K\bar{K}$ production in the reactions $\pi N \to N K\bar{K}$ and $N N \to N N K\bar{K}$ has been considered. The results of calculations for the $\pi N \to N K\bar{K}$ cross sections in different isospin channels showed that the $a_0$-resonant part is expected to be more pronounced at $Q \leq 250$ MeV while the non-resonant background might become dominant at $Q \geq 250$ MeV (see Fig. 4 in Ref. [30]). The analysis of different isospin channels of the reaction $NN \to N N K\bar{K}$ demonstrated that the production of the $a_0$ — as compared to the background — is more pronounced in the reaction $pp \to pnK^+\bar{K}^0$ than in the reaction $pp \to ppK^+\bar{K}^-$.

Here we use these previous results to analyze the role of the non-resonant background in the $pp \to dK^+\bar{K}^0$ reaction. The diagrams describing $\pi - K^* - \pi(\eta)$- and $K$-exchange mechanisms are shown in Fig. 2(a) and b), respectively. The results of the calculations are presented in Fig. 4. The dash-dotted and dotted lines in Fig. 4 display the background corresponding to $\pi - K^* - \pi$- and $\pi - K^* - \eta$- exchange mechanisms, respectively, while the $K$-exchange contribution is shown by the short-dashed line. It can be seen from Fig. 4 that this contribution is much smaller than the cross section for the $\pi - K^* - \pi$-exchange and may safely be neglected.

As follows from the $G$-parity constraints (see comment after Eq. (15)) the $\pi - K^* - \pi$ mechanism contributes mainly to the $P$-wave in the $K^+\bar{K}^0$-system, while the $\pi - K^* - \eta$- mechanism contributes dominantly to the $S$-wave. The latter, in principle, via $KK$-FSI can contribute to the resonant $a_0$ channel where the kaons are also produced in a relative $S$-wave. However, we neglect this in the following since the contribution from this channel is very small (see dotted line in Fig. 4) and conclude that $K\bar{K}$ pairs from background will predominantly be in a $P$-wave, while in the case of $a_0$ decay it will be produced in the $S$-wave (see also Section 2 and Ref. [30]). According to the long-dashed line in Fig. 4 the resonant part is dominant up to $Q \simeq 100$ MeV. The background is seen to give an important contribution only for $Q \geq 100$ MeV.

As mentioned before, the TSM gives an integrated cross section of about 28 nb at $Q = 46$ MeV for the $a_0$ resonance part. As concerning the contribution of the $P$-wave $K\bar{K}$ pairs, we normalized it here to 6.5 nb at the same $Q$. This value was obtained in Ref. [28] from the best fit to the data. To describe it within the $\pi - K^* - \pi$-exchange model we use a cut-off parameter $\Lambda_{K\bar{K}}(K^*\pi K) = 1.25$ GeV. Using Eqs. (2), (4), (6) and (14)-(15) one can find that the leading term for the $K\bar{K}$-wave part of the $pp \to dK^+\bar{K}^0$ amplitude has the following spin structure

\[ T_{pp-+}^{P-K\bar{K}-\pi} \sim \varphi_{\lambda_a}(p_a) \langle \sigma \cdot p_a \rangle \varphi_{\lambda_b}(p_b) \times \langle \sigma \cdot p_a \rangle \varphi_{\lambda_a}(p_a) \varphi_{\lambda_b}(p_b) \],

Therefore, within the $\pi - K^* - \pi$-exchange model the background has the following angular distribution

\[ \frac{d\sigma}{d\Omega_{12}} \simeq N \cos^2 \theta_{12}, \]
4.1 Spin structure of the $NN \rightarrow da_0$ amplitude in the QGSM

The spin dependence of the $\gamma d \rightarrow pn$ amplitude has been evaluated in Ref. \[40\] by assuming that all intermediate quark clusters have minimal spins and the $s$-channel helicities in the quark–hadron and hadron–quark transition amplitudes are conserved. In this limit the spin structure of the amplitude $T(\gamma d \rightarrow pn)$ can be written as (see Ref. \[40\], comment after Eq. (27))

$$\langle p_3, \lambda_3; p_4, \lambda_4 | T(s, t) | p_2, \lambda_2; p_1, \lambda_1 \rangle \approx u_{\lambda_2}(p_2) \epsilon_{\lambda_1} \times [A_{\gamma d \rightarrow pn}(s, t)(\hat{p}_3 - \hat{p}_1) + B_{\gamma d \rightarrow pn}(s, t)m] \epsilon_{\lambda_3} \hat{v}_{\lambda_4}(p_4), \tag{21}$$

where $m$ is the nucleon mass, $p_1$, $p_2$, $p_3$, and $p_4$ are the 4-momenta of the photon, deuteron, proton and neutron, respectively, and $\lambda_i$ denotes the $s$ channel helicity of the $i$-th particle. The invariant amplitudes $A_{\gamma d \rightarrow pn}(s, t)$ and $B_{\gamma d \rightarrow pn}(s, t)$ have similar Regge asymptotics (see below). It is possible to show (cf. Ref. \[40\]) that at small scattering angles the ratio $R_{\gamma d} = A_{\gamma d \rightarrow pn}(s, t)/B_{\gamma d \rightarrow pn}(s, t)$ is a smooth function of $t$ and can be considered as an effective constant that depends on the ratio of the nucleon mass to the constituent quark mass $m_q$: $R \approx m/(2m_q)$. We note that such a simple interpretation of $R$ in general does not work at large scattering angles.

It is interesting to note that the spin structure of the $\gamma d \rightarrow pn$ amplitude in Eq. (21) is very similar to the amplitude within the Reggeized Nucleon Born Term Approach (RNBTA) where the $R_{\gamma d} = 1$ is directly related to the spin structure of the nucleon propagator (see Refs. \[15, 15\]).

In complete analogy with Eq. (21), the spin structure of the amplitude $T(pp \rightarrow da_0^0)$ can be written as

$$\langle q_2, \lambda_2; q_0, \lambda_0 | T(s, t) | p_a, \lambda_a; p_b, \lambda_b \rangle \approx \hat{v}_{\lambda_a}(p_a) \epsilon_{\lambda_b}^* \times [A_{pp \rightarrow da_0^0}(s, t)(\hat{q}_2 - \hat{q}_0) + B_{pp \rightarrow da_0^0}(s, t)m] \hat{u}_{\lambda_b}(p_b), \tag{22}$$

In order to achieve consistency of the differential cross section $d\sigma/dt$ with the Regge behaviour we use the following parametrization of the amplitude $B_{pp \rightarrow da_0^0}(s, t)$

$$|B_{pp \rightarrow da_0^0}(s, t)|^2 = \frac{1}{s} |\mathcal{M}_{\text{Regge}}(s, t)|^2, \tag{23}$$

where

$$\mathcal{M}_{\text{Regge}}(s, t) = F(t) \left( \frac{s}{s_0} \right)^{\alpha_N(t)} \exp \left[ -\frac{\pi}{2} \left( \alpha_N(t) - \frac{1}{2} \right)^2 \right]. \tag{24}$$

Here $\alpha_N(t)$ is the trajectory of the nucleon Regge pole and $s_0 = 4 \text{ GeV}^2 \approx m_N^2$. We take the dependence of the residue $F(t)$ on $t$ in the form

$$F(t) = B_{\text{res}} \left[ \frac{1}{m^2 - t} \exp(R_1^2 t) + C \exp(R_2^2 t) \right]. \tag{25}$$
as used previously in Refs. [47,48] for the description of the reactions $pp \to d\pi^+$ and $\bar{p}d \to p\pi^-$ at $-t \leq 1.6$ GeV$^2$ as well as for the analysis of deuteron photodisintegration at $E_\gamma \geq 1$ GeV (see Ref. [40]). In Eq. (25) the first term in the square brackets contains the nucleon pole and the second term accounts for the contribution of non-nucleonic degrees of freedom in the deuteron.

The amplitudes defined by Eqs. (21) and (22) have a rather simple covariant structure and can be extrapolated to large angles. As shown in Ref. [40] the energy behavior of the cross section for the reaction $\gamma d \to pn$ at large angles crucially depends on the form of the Regge trajectory $\alpha_N(t)$ for large negative $t$. Best agreement with experimental data is obtained for a logarithmic form:

$$\alpha_N(t) = \alpha_N(0) - (\gamma \nu) \ln(1 - t/T_B),$$

where the intercept $\alpha_N(0) = -0.5$, the slope $\alpha_N'(0) = 0.8 \div 0.9$ GeV$^{-2}$ and $T_B = 1.5 \div 1.7$ GeV$^2$. We adopt the following values for the parameters of the residue $F(t)$ of Eq. (25):

$$C = 0.7 \text{ GeV}^{-2}, \quad R_1^2 = 1 \div 2 \text{ GeV}^{-2}, \quad R_2^2 = 0.03 \text{ GeV}^{-2}.$$ These parameters of the residue and trajectory, except for the overall normalization factor $B_{\text{res}}$, are not very different from those determined by fitting data on the reactions $pp \to d\pi^+$ at $-t \leq 1.6$ GeV$^2$ [47] and $\gamma d \to pn$ at $E_\gamma \geq 1$ GeV [40].

We considered the $pp \to da_0^+$ amplitude [22] within the RNBTA, i.e. for a fixed ratio

$$R_{\text{rad}} = A_{pp \to da_0^+}(s,t)/B_{pp \to da_0^+}(s,t) = 1,$$

as well as its generalization corresponding to the QGSM. The spin structure of the amplitude within the QGSM takes into account quark degrees of freedom and the parameter $R_{\text{rad}}$ may be different from 1. In line with Ref. [23] we also treat the ratio $R_{\text{rad}}$ as a free parameter. The parameters of the residue, trajectory and the ratio $R_{\text{rad}}$ used for our calculations are given in Tables 1 and 2.

### 4.2 Numerical results

In Fig. 6 we show the $a_0$ resonance contribution to the $pp \to dK^+K^0$ cross section calculated within the QGSM (dashed curve) as well as the prediction of the TSM long-dashed line). The dash-dotted line displays the background corresponding to the $\pi - K^* - \pi$ exchange mechanism. Since we have $K\bar{K}$ pairs in a relative S-wave basically due to direct $a_0$ resonance production, we have normalized the results of the QGSM at $Q = 46$ MeV to the experimental value 31.5 nb, which was found for the $K\bar{K}$ S-wave part [24]. The corresponding values of the normalization factor $B_{\text{QGSM}}$ are given in Table 2. In Fig. 6 we display the result of the QGSM with parameters of Set($a_0d$). Since the calculations with Set($\gamma d$) give practically the same answer we discard an explicit representation in this figure. As seen from Fig. 6 the energy dependence of the $a_0$ resonance contribution of the cross section predicted by the TSM and QGSM is very similar at $Q \leq 200$ MeV. The solid line in Fig. 6 displays the sum of the $a_0$ resonance production cross section calculated within the QGSM and the $K\bar{K}$ $P$-wave background contribution.

In order to check the consistency of our model for the $a_0$ production in the $pp \to da_0^+$ reaction we compare the calculated forward differential cross section with the LBL data [31] in Fig. 8. The dotted line shows the prediction of the RNBTa. The calculations within the QGSM — normalized to the ANKE data on the reaction $pp \to da_0^+ \to K^+K^0$ are in a good agreement with the differential cross sections measured at LBL [31] (open circles).

The calculated angular and invariant mass distributions for the $pp \to dK^+K^0$ reaction at $Q = 46$ MeV in comparison to the experimental data [26] are shown in Fig. 8. The dashed lines correspond to $K^+K^0$ production through the $a_0$ resonance and has been calculated within the QGSM using the parameters from Set($a_0d$). The dashed-dotted lines describe the $K\bar{K}$ $P$-wave background calculated within the $\pi - K^* - \pi$-exchange model. The solid lines indicate the sum of the $a_0$ resonance and background contributions. In the upper part of the figure we show also the angular distribution for deuteron calculated in the QGSM with parameters of Set($\gamma d$). The almost isotropic angular dependence given by this version of the QGSM (thin solid line) is in a reasonable agreement with the data. The angular distribution of deuteron for the $a_0$ contribution as calculated within the RNBTa is presented by the dotted line and gives a sharp forward peak similarly to the nonrelativistic two-step model [28]. Therefore, both models — TSM and RNBTa — are not able to reproduce the experimental deuteron an-
Table 1. Parameters of the Regge trajectory \( \text{RNBTA} \) and the residue \( \text{QGSM} \) for the reactions \( \gamma d \rightarrow pn \) (Set(\( \gamma d \)) and \( pp \rightarrow da_0^+ \) (Set(\( a_0d \))).

Table 2. Parameters of the trajectory and residue, normalization factor \( B_{\text{res}} \) and the ratio \( R_{a_0d} \) used for the \( pp \rightarrow da_0^+ \) amplitude calculation within the RNBTA and QGSM.

| Parameters            | RNBTA | QGSM |
|-----------------------|-------|------|
| trajectory & residue | Set(\( \gamma d \)) | Set(\( \gamma d \)) | Set(a_0d) |
| \( B_{\text{res}} \) [nb\(^{1/2}\) GeV\(^{-3}\)] | 5.23 \times 10^3 | 3.19 \times 10^3 | 2.67 \times 10^3 |
| \( R_{a_0d} \)        | 1     | -4   | -4   |

Fig. 7. Forward differential cross section of the reaction \( pp \rightarrow da_0^+ \) as a function of the c.m. excess energy. The open dots are the experimental data from Ref. [31]. The dotted line shows the prediction of the RNBTA. The thin and bold dashed curves display the results of the QGSM with parameters of Set(\( \gamma d \)) and Set(a_0d), respectively.

From the contribution from the \( K^+\bar{K}^0 \) P-wave background: Most of the events related to the \( a_0 \) resonance are concentrated in the lower part of the \( K^+\bar{K}^0 \) mass spectrum, whereas the main contribution of the background shows up at higher invariant mass.

5 Final state interactions

As has been stressed in Ref. [27] the reaction \( pp \rightarrow dK^+\bar{K}^0 \) might be sensitive to both the \( K^+\bar{K}^0 \) and \( Kd \) final-state interactions (FSI). The interaction of the \( K^+ \) with protons and neutrons is rather weak [49] and following Ref. [27] we will neglect it. Within our model we can describe the \( S \)-wave \( K\bar{K} \) cross section by direct \( a_0^+ \) production with subsequent decay \( a_0^+ \rightarrow K^+\bar{K}^0 \). Contributions from non-resonant \( S \)-wave \( K\bar{K} \) production turned out to be negligible small, whereas the \( P \)-wave \( K\bar{K} \) FSI it is small due to centrifugal suppression. Thus we only have to consider the \( \bar{K}d \) FSI. To estimate the role of the \( S \)-wave \( \bar{K}d \) FSI we use the Foldy-Brueckner adiabatic approach based on the multiple scattering (MS) formalism (see Ref. [50]). Note that this method has already been used for the calculation of the enhancement factor for the reactions \( pd \rightarrow \bar{K}d \) [51] and \( pn \rightarrow d \eta \) [32].

In the Foldy-Brueckner adiabatic approach the \( \bar{K}d \) wave function — defined at fixed coordinates of the proton \( (r_p) \) and the neutron \( (r_n) \) (see Ref. [50] for details) — reads as:

\[
\Psi_k(r_{\bar{K}d}, r_p, r_n) = \exp(ikr_{\bar{K}d}) + \frac{t_{\bar{K}d} r_{\bar{K}d} \exp(ikr_{\bar{K}d})}{D} + \frac{t_{\bar{K}d} r_{\bar{K}d} \exp(ikr_{\bar{K}d})}{D} \cdot \exp(ikr_p) + \frac{t_{\bar{K}d} r_{\bar{K}d} \exp(ikr_{\bar{K}d})}{D} \cdot \exp(ikr_n),
\]

where

\[
D = \left( 1 - t_{\bar{K}d} r_{\bar{K}d} \frac{\exp(2ikr_p)}{r_{\bar{K}d}} \right). \tag{27}
\]

Here \( r_{\bar{K}d} = r_p - r_n, r_{\bar{K}d} = r_{\bar{K}d} - r_p, r_{\bar{K}d} = r_{\bar{K}d} - r_n \) and \( k = \frac{m_0 + m_{\bar{K}d}}{m_0} \).
Fig. 8. Angular distributions (upper and middle part) and invariant mass distribution (lower part) for the $pp \rightarrow dK^+\bar{K}^0$ reaction at $Q = 46$ MeV in comparison with the data from Ref. [26]. The dashed (dashed-dotted) line corresponds to $K^+\bar{K}^0$ production in a relative $S$-($P$-) wave and the solid line is the sum of both contributions. The $a_0$-resonance contribution shown by the bold and thin dashed lines results from the QGSM with parameters of Set$(a_0d)$ and Set$(\gamma d)$, respectively. The dotted line is the result from the RNBTA. $\Theta_d$ and $\Theta_{12}$ are the polar angles for the c.m. deuteron momentum and for the $K\bar{K}$ relative momentum, respectively.

Note that we use the unitarized scattering length approximation for the latter, i.e.

$$f^I_{K\bar{N}}(k_{K\bar{N}}) = \left((a^I_{K\bar{N}})^{-1} - ik_{K\bar{N}}\right)^{-1}, \quad (30)$$

where $k_{K\bar{N}}$ is the modulus of the relative $K\bar{N}$ momentum and $I$ denotes the isospin of the $K\bar{N}$ system.

The $K^0d$-scattering length then is defined as

$$A_{K^0d}^{MS} = \frac{m_d}{m_{K^0} + m_d} \times \left\{ \frac{t_{K^0p}(k_{K^0p} = 0) + t_{K^0n}(k_{K^0n} = 0) + t_{r}}{1 - t_{K^0p}(k_{K^0p} = 0)t_{K^0n}(k_{K^0n} = 0)/t^2} \right\}, \quad (31)$$
and the FSI enhancement factor as
\[ \lambda^{MS}(1_0) = |\langle \Psi_{K}(r_{K^0} = 0, r_p = r/2, r_n = -r/2) |^2 \]. (32)

In Eq. (31) we have used the abbreviation
\[ t_r = \frac{2t_{K^0}(k_{K^0} = 0)t_{K^0}(k_{K^0} = 0)}{r} \]. (33)

To describe the deuteron structure we use the Paris wave function [52]. The \( \bar{K}N \) scattering lengths \( a_{KN}^0 \) and \( a_{KN}^\pm \) are taken from Ref. [53]:
i) \( a_0 = -1.57 + i 0.78 \) fm, \( a_1 = 0.32 + i 0.75 \) fm (CSL set);
ii) \( a_0 = -1.59 + i 0.76 \) fm, \( a_1 = 0.26 + i 0.57 \) fm (\( K \)-matrix set).

We recall that the \( \bar{K}N \) scattering length is strongly repulsive for the isospin channel \( I = 0 \) and moderately attractive for \( I = 1 \). In the single scattering approximation then a slight repulsion adds up for the \( \bar{K}d \) system \( A_{\bar{K}d}^i = -0.39 + i 1.72 \) fm [53].

Results from Faddeev calculations with separable \( \bar{K}N \) potentials — as carried out in Ref. [54] — give \( A_{\bar{K}d} = -1.34 + i 1.04 \) fm, i.e., they predict a larger \( \bar{K}d \) repulsion. We remind the reader that a repulsion in the low-energy \( \bar{K}d \) system can lead to a FSI suppression factor (< 1); on the other hand, any attraction leads to a FSI enhancement factor (> 1).

Evidently, the FSI effect is most important close to threshold and is due to the long-range coherent \( S \)-wave \( \bar{K}d \) interaction. Therefore, one can safely assume that the range of the FSI is much larger than the range of the 'hard' interaction, which is responsible for the production of the \( \bar{K}K \)-meson pair. In this case the basic production amplitude and the FSI can be factorized [50], i.e. the FSI can be taken into account by multiplying the production cross section by the FSI factor.

The partial wave structure of the final state for the basic production amplitude corresponds to \( |[\bar{K}^0K^+], d_p |, \) for the production and \( |[\bar{K}^0K^+], p |, \) for the \( \bar{K}K \) background. To calculate the corresponding FSI factors we expressed these partial waves in terms of partial amplitudes of the second basis with \( |[\bar{K}^0K^+], p |, \) for the \( \bar{K}K \) background.

The invariant mass distributions for the \( K^+K^0 \) and \( d\bar{K}^0 \) systems are shown in Figs. [10] and [11] for \( Q = 46 \) MeV and 107 MeV, respectively. The dashed (upper) lines are calculated for the resonance contributions, while the dash-dotted (lower) lines stand for the non-resonance contributions. The bold lines describe the contributions calculated without FSI, where the thin lines with FSI are always slightly lower in line with Fig. [10].

We note that the QGSM cannot predict the absolute value of the cross section and has been 'normalized’ to the data at 46 MeV. If we rescale the respective mass distribution up by \( \sim 20 \% \) we obtain distributions practically identical to the bold dashed lines calculated without FSI. Therefore, increasing the normalization of the QGSM by 1.2 our calculations for the \( K^+K^0 \) and \( d\bar{K}^0 \) mass distributions will be again in a good agreement with the ANKE data [26]. Let us note that the predictions of Ref. [27] on strong distortions of the \( K^+K^0 \) and \( K^0d \) invariant mass spectra by the \( K^0d \) FSI were not confirmed by the experiment [26].

We finally address the validity of the FSI model employed here. The multiple scattering (or fixed center) approach (MSA) was applied to the calculations of the \( K^-d \) scattering length in Ref. [53] before and has also been compared to full multi-channel Faddeev calculations in Ref. [54]. In the latter studies it was found that the MSA — with a single-channel absorptive \( \bar{K}N \) interaction — gives quite reliable estimates for the real and imaginary parts of the \( K^-d \) scattering length. Our results for the latter are in reasonable agreement with the calculation of Ref. [53]: we found \( A_{\bar{K}d} = -0.78 + i 1.23 \) fm for the \( K^-d \) matrix set while Ref. [54] gives \( A_{\bar{K}d} = -0.72 + i 0.94 \) fm which has to be multiplied additionally by the 'reduced mass'
V. Yu. Grishina et al.: Near-threshold production of $a_0(980)$ mesons

Fig. 11. Invariant mass distributions for the $K^+\bar K^0$ (upper part) and $d\bar K^0$ (lower part) systems for the reaction $pp \to dK^+\bar K^0$ at $Q=46$ MeV. The dashed (dash-dotted) lines are calculated for the resonance (non-resonance) contributions. The bold (thin) curves describe the contributions without (with) the FSI included. The experimental data are taken from Ref. [26].

This gives $A_{r_{K^0d}} = -0.85 + i 1.11$ fm. The agreement with our result is evidently quite good.

Fig. 12. Invariant mass distributions for the $K^+\bar K^0$ (upper part) and $d\bar K^0$ (lower part) systems for the reaction $pp \to dK^+\bar K^0$ at $Q=107$ MeV. The assignment of the individual lines is the same as in Fig. 11.

6 Conclusions

In this work we have performed a detailed study of $a_0$ production in the reaction $NN \to dK^+\bar K^0$ near threshold and at medium energies. Using the two-step model (TSM) based on an effective Lagrangian approach with one-pion exchange in the intermediate state we have analyzed different contributions to the cross section of the reaction $NN \to da_0$ corresponding to $t$-channel diagrams with $\eta$- and $f_1(1285)$-meson exchanges as well as $s$ and $u$-channel graphs with an intermediate nucleon. We have also considered the $t$-channel Reggeon mechanism with $b_1$ and $\rho_2$ exchanges with parameters normalized to the Brookhaven data for $\pi^{-}p \to a_0^0n$ at 18 GeV/c [38]. These results have been used to calculate the contribution of $a_0$ mesons to the cross section of the reaction $pp \to dK^+\bar K^0$. We found that the dominant contribution is given by the nucleon $u$-channel mechanism.

Within this approach, which is practically equivalent to a direct normalization of the $u$-channel contribution to the LBL data [51] on the forward differential cross section of the reaction $pp \to a_0^0$ at 3.8 GeV/c, we could reproduce fairly well the total cross section of the reaction $pp \to dK^+\bar K^0$ at 3.46 GeV/c ($Q=46$ MeV) as measured at COSY [26]. However, the TSM failed to reproduce the experimental distribution in the deuteron scattering angle.
As an alternative and more general approach we have employed the Quark-Gluon Strings Model (QGSM), that recently has successfully been applied to the description of deu-teron photodisintegration data [40,42]. Within the QGSM there is an almost complete analogy between the amplitudes of the reactions $\gamma d \rightarrow pn$ and $NN \rightarrow d_0$ because both are described by planar graphs with three valence-quark exchange in the $t$ (or $u$)-channels (cf. Fig. 5). Normalizing the QGSM predictions to the total cross section of the reaction $pp \rightarrow da_0^\pi \rightarrow dK^+\bar{K}^0$ at $Q = 46$ MeV we have calculated the energy dependence of the cross section as well as the angular and mass distributions at $Q = 46$ and 107 MeV. In the QGSM we were able to reproduce the differential experimental distributions at $Q=46$ MeV. We have, furthermore, demonstrated that the QGSM gives also a rather good description of the LBL data at intermediate energies. In order to test the QGSM and its implications we have made detailed predictions for an excess energy of 107 MeV that can be controlled experimentally in the near future.

We also analyzed the non-resonant $KK$-pair production using a model with $\pi - K^* - \pi (\eta)$- and $K$-exchange mechanisms. It is found that the $K$-exchange mechanism can be neglected. As following from $G$-parity arguments the $\pi - K^* - \pi$ mechanism contributes mainly to the $P$-wave in the $K^+\bar{K}^0$-system, while the $\pi - K^* - \eta$-mechanism contributes dominantly to the $S$-wave. The latter channel turned out to be negligibly small. In addition we have explored the effects from final-state interactions (FSI) in these reactions for the resonant and non-resonant channels. Due to an effective repulsive interaction in the $Kd$ system the FSI factor turns out to be smaller than one. However, the net suppression found is only in the order of 20% for the $a_0$ channel, while the background is suppressed by up to $\sim 30\%$. Moreover, the shape of the invariant mass distributions in the $K^+\bar{K}^0$ and $K^0d$ channels is practically not influenced by the FSI.

In summary, we conclude that the reaction $pp \rightarrow dK^+\bar{K}^0$ at excess energies $Q < 100$ MeV should be dominated by the intermediate production of the $a_0(980)$-resonance. For $Q \geq 100$ MeV the non-resonant $K^+\bar{K}^0$-pair production can be important, however, this background gives a dominant contribution to the $K^+\bar{K}^0$ $P$-wave at higher $K^+\bar{K}^0$ invariant mass. This implies that the experimental program on the study of near-threshold $a_0$ and $f_0$ production in $pp$, $pn$, $pd$ and $dd$ interactions at COSY-Jülich [21,22] is promising since the $a_0$ signal in the $KK$ mode can reliably be separated from the non-resonant $KK$ background.

**Appendix**

In this appendix we present the $\pi N \rightarrow Na_0$ amplitudes which were used in Section 3 for the calculation of the resonant contribution to the reaction $pp \rightarrow dK^+\bar{K}^0$.

The $t$-channel $f_1$ (1285) and $\eta$ exchanges are described by the expressions

$$M_{f_1} (\pi^- p \rightarrow a_0^- p) = g_{f_1a_0a_0} g_{f_1NN} \frac{1}{t-m_{\eta}^2} F_{f_1a_0a_0}(t) F_{f_1NN}(t),$$

(35)

$$M_{f_1} (\pi^- p \rightarrow a_0^- p) = g_{f_1a_0a_0} g_{f_1NN} \frac{1}{t-m_{\eta}^2} F_{f_1a_0a_0}(t) F_{f_1NN}(t).$$

Here $p_1$ and $p_2'$ are the four momenta of $\pi^-$ and $a_0^-$, whereas $p_2$ and $p_2'$ are the four momenta of the initial and final protons, respectively, and $q = p_2' - p_2, t = (p_2' - p_2)^2$. The form factors $F_j(t)$ at the different vertices $j (j = f_1NN, \eta NN)$ are taken in the form (7).

In the case of $\eta$ exchange we use $g_{\eta NN} = 6.1, A_{\eta NN}=1.5$ GeV from [57] and $g_{\eta a_0} = 2.2$ GeV (see [50]). The contribution of the $f_1$ exchange is calculated using $g_{f_1NN} = 14.6, A_{f_1NN} = 2$ GeV from [57] and $g_{f_1a_0a_0} = 2.5$. The latter value for $g_{f_1a_0a_0}$ corresponds to $\Gamma (f_1 \rightarrow a_0\eta) = 24$ MeV and $Br (f_1 \rightarrow a_0\eta) = 34\%$ (see Ref. [59]). Eq. (35) as well as Eq. (40) can be represented in the form (13) with the invariant amplitudes $A(s, t)$ and $B(s, t)$ given by

$$A(\eta)(s, t) = -g_{\eta a_0a_0} g_{\eta NN} \frac{F_{\eta a_0a_0}(t) F_{\eta NN}(t)}{t-m_{\eta}^2},$$

(37)

for the $\eta$-exchange contribution and

$$A^{(f_1)}(s, t, u) = 2m_{\gamma} s + t + u - 2(m_{a_0}^2 + m_N^2)$$

$$\times g_{f_1a_0a_0} g_{f_1NN} \frac{F_{f_1a_0a_0}(t) F_{f_1NN}(t)}{t-m_{f_1}^2},$$

(38)

$$B^{(f_1)}(s, t) = 2 g_{f_1a_0a_0} g_{f_1NN} \frac{F_{f_1a_0a_0}(t) F_{f_1NN}(t)}{t-m_{f_1}^2},$$

(39)

for the $f_1$-exchange.

The amplitudes of the $s$- and $u$-channel contributions are defined by the standard expressions:

$$M_N^{1\pi^- p \rightarrow a_0^\pi^- n} = -\sqrt{2}g_{a_0NN} \pi p_{NN} \frac{1}{m_\pi} \frac{1}{s-m_N^2} F_N(s)$$

$$\times \pi p_{\eta} \frac{1}{t-m_\eta^2} F_{\eta NN}(t),$$

(40)

$$M_N^{1\pi^- p \rightarrow a_0^\pi^- n} = \sqrt{2}g_{a_0NN} \pi p_{NN} \frac{1}{m_\pi} \frac{1}{u-m_N^2} F_N(u)$$

$$\times \pi p_{\eta} \frac{1}{t-m_\eta^2} F_{\eta NN}(t),$$

where $s = (p_1+p_2)^2, u = (p_2'-p_2)^2, m_N$ is the nucleon mass, $F_{\eta NN}^2/4\pi = 0.08$ [27]. The form factor for a virtual nucleon is taken as

$$F_N(u) = \left( \frac{A_N^2}{A_N^2 + (u-m_N^2)^2} \right)^j,$$

where $j = 2, A_N$ is the cut-off parameter chosen as $A_N = 1.3$ GeV. In Ref. [50] it was found that the $u$-channel $a_0$ resonance contribution to the $\pi^+ p \rightarrow pK^+\bar{K}^0$ reaction calculated...
with the nucleon form factor \( F_N(u) \) \(^{(21)}\) of dipole type \((j=2)\)
with \( A_N \leq 1.35 \text{ GeV} \) is in a reasonable agreement with existing experimental data.

Coming back to the amplitudes \( A(s,t) \) and \( B(s,t) \) defined by Eq. \((13)\) we find
\[
A^{(s)}(s,t) = \sqrt{2} \frac{(s + m_N^2)}{g_{\pi NN}} \frac{F_{\pi NN}}{m_\pi} \frac{F_N(s)}{s - m_N^2},
\]
\[
B^{(s)}(s,t) = -\sqrt{2} 2 m_N g_{\pi NN} \frac{F_{\pi NN}}{m_\pi} \frac{F_N(s)}{s - m_N^2}
\]
for the \( s \)-channel contribution and
\[
A^{(u)}(u,s) = -\sqrt{2} \frac{(u + m_N^2)}{g_{\pi NN}} \frac{F_{\pi NN}}{m_\pi} \frac{F_N(u)}{u - m_N^2},
\]
\[
B^{(u)}(u,s) = \sqrt{2} 2 m_N g_{\pi NN} \frac{F_{\pi NN}}{m_\pi} \frac{F_N(u)}{u - m_N^2}
\]
in the case of the \( u \)-channel mechanism.

In the case of the Regge-pole model with the \( p_2 \) and \( b_1 \) exchanges we have used the parametrization for \( A(s,t) \) and \( B(s,t) \) as suggested by Achasov and Shostakov
\[
A^{\text{(Regge)}}(s,t) \approx \frac{\gamma_{p_2}}{\sqrt{s_0}} \exp \left[ -\frac{i\pi}{2} \alpha_{b_1}(t) \right] \left( \frac{s}{s_0} \right)^{\alpha_{b_1}(t)},
\]
\[
B^{\text{(Regge)}}(s,t) \approx \frac{-\gamma_{b_1}}{s_0} \exp \left[ -\frac{i\pi}{2} \alpha_{b_1}(t) \right] \left( \frac{s}{s_0} \right)^{\alpha_{b_1}(t)}
\]
where
\[
\gamma_{p_2}(t) = \gamma_{p_2}(0) \exp(b_2 t),
\]
\[
\gamma_{b_1}(t) = \gamma_{b_1}(0) \exp(b_1 t),
\]
and \( s_0 \approx 1 \text{ GeV}^2 \). The meson Regge trajectories were taken in the linear form \( \alpha_j(t) = \alpha_j(0) + \alpha_j'(0) t \). The parameters of the residues \( \gamma_{p_2}(0) \), \( b_2 \) and \( \gamma_{b_1}(0) \), \( b_1 \) were fixed in Ref. \(^{20}\) using the Achasov and Shostakov fit of the Brookhaven data on the \( \pi^- p \to a_0^N \) reaction at 18 GeV/c \(^{38}\). They found two solutions with the relative \( b_1 \) contribution equal to 0 (fit 1) and 30% (fit 2). We use these two different choices of the Regge model for the analysis of the \( \pi^N \to a_0 N \) reaction.

Acknowledgements

We are very grateful to C. Hanhart for many useful discussions and clarifying remarks. This work was supported by DFG (grant 436 RUS 113/630) and by Russian Fund for Basic Research (grants 02-02-16783 and 03-02-04025).
