Abstract
We define a bicomplex whose Euler characteristic is the idempotented version of the ribbon element of quantum $sl(2)$. We show that properties of this bicomplex descend to the centrality, invertibility, and symmetries of the ribbon element after decategorification.

Keywords Quantum $sl(2)$ · Ribbon element · Bicomplex

1 Introduction

The program of categorification of quantum groups was initiated by Frenkel and carried out by Khovanov and Lauda [8–10] and Rouquier [16]. In [11, 12], the 2-category $\mathcal{U}$ was constructed that categorifies the integral idempotented version of the quantum enveloping algebra of $sl_2$.

The objects of $\mathcal{U}$ are natural numbers, interpreted as the integral weight lattice of $sl_2$. The 1-morphisms of $\mathcal{U}$ are generated by $E(a)_{1n}(t)$ and $F(b)_{1n}(t)$, for all $a, b \in \mathbb{N}, n, t \in \mathbb{Z}$, which are lifts of the Lusztig divided powers. The 2-morphisms are $\mathbb{Z}$-linear combinations of planar diagrams modulo local relations. The split Grothendieck group $K_0(\mathcal{U})$ satisfies

$$K_0\left(\mathcal{E}(a)_{1n}(t)\right) = q^l E(a)_{1n}$$

and coincides with the integral idempotented version of the quantum enveloping algebra $U_q(sl_2)$ constructed in [1].

On the other hand, there exists a universal knot invariant [13] (see also [7]) which takes values in the center of quantum $sl_2$ and dominates all colored Jones polynomials. The quantum Casimir operator generating the center of $U_q(sl_2)$ was categorified in [2]. This paper can be considered as the next step towards a categorification of the universal link invariant.
The most challenging problem of this program is to find a categorical equivalent of the $R$-matrix, associated by the universal invariant to a crossing in a link diagram. Here we resolve a simpler problem, we categorify the ribbon element, which is the universal invariant of a self-crossing. The bicomplex we construct in this paper is conjecturally an element of the Drinfeld center of $\text{Com}(\mathcal{U})$ and is related to a Serre functor on category $\mathcal{O}$ associated with the longest braid [15] by Conjecture 1.3. Here we denote by $\text{Kom}(\mathcal{U})$ the category of bicomplexes over the 2-category $\mathcal{U}$ and by $\text{Com}(\mathcal{U})$ its homotopy version.

The ribbon element $r$ is an element of the $h$-adic version $U_h(sl_2)$ of the quantized enveloping algebra $U_q(sl_2)$. It is given by

$$r = q^{-n^2 - H} \sum_{k=0}^{\infty} (-1)^k q^{-kH - k} (q^{-2}; q^{-2})_k F^{(k)} E^{(k)},$$

where $(q^a; q^b)_k = (1 - q^a)(1 - q^{a+b}) \ldots (1 - q^{a+(k-1)b})$. Thus, the idempotented version of $r$ is

$$r_1 n = q^{-n^2 - n} \sum_{k=0}^{\infty} (-1)^k q^{-kn - k} (q^{-2}; q^{-2})_k F^{(k)} E^{(k)} 1_n$$

(1.1)

where $n \in \mathbb{Z}$.

Recall that the ribbon element is central and invertible in $U_q(sl_2)$ with the inverse

$$r^{-1} 1_n = q^{-n^2 + n} \sum_{k=0}^{\infty} (-1)^k q^{kn + k} (q^2; q^2)_k F^{(k)} E^{(k)} 1_n.$$

The definition of the bicomplex $r1_n \in \text{Kom}(\mathcal{U})$ categorifying the ribbon element is outlined as follows. First, we construct a bicomplex $C_{\bullet, \bullet}$ in $\text{Kom}(\mathcal{U})$

$\begin{array}{c}
C_{00} \\
\downarrow d^{V}_{00} \\
\vdots \\
C_{10} \to C_{11} \\
\downarrow d^{H}_{10} \\
\vdots \\
C_{20} \to C_{21} \to C_{22} \\
\downarrow d^{V}_{20} \\
\vdots \\
C_{30} \to C_{31} \to C_{32} \to C_{33} \\
\downarrow d^{V}_{30} \\
\vdots
\end{array}$

(1.2)

where the 1-morphism $C_{k,l} : n \to n$ in $\mathcal{U}$ (i.e., an object $C_{k,l}$ in the additive category $\mathcal{U}(n,n)$) is defined by

$$C_{k,l} := F^{(k)} E^{(l)} 1_n (-kn - k) \otimes A^l W_k,$$

where $W_k = \text{Span}_\mathbb{Z}\{w_1, \ldots, w_k\}$ with $\deg(w_j) = -2j$. Note that $C_{00} = F^{(0)} E^{(0)} 1_n(0) \otimes A^0 W_0 \cong 1_n$. The differentials $d^{V}_{k,l}, d^{H}_{k,l}$ are defined in Section 4. Figure 1 shows the
beginning of this bicomplex. The Euler characteristic of the bicomplex \( C_{\bullet, \bullet} \) is equal to the sum part of (1.1)

\[
\sum_{k=0}^{\infty} (-1)^k q^{-kn-k} (q^{-2}; q^{-2})_k F^{(k)} E^{(k)} 1_n.
\]

Finally, we shift our bicomplex by \( \langle -\frac{n^2}{2} - n \rangle \) in \( q \)-degree and by \([n/2, n/2]\) in homological bi-degree to obtain

\[
r^{-1}1_n := C_{\bullet, \bullet} \begin{pmatrix} -\frac{n^2}{2} - n \end{pmatrix} [n/2, n/2].
\]

The \( q \)-degree shift \( \langle -\frac{n^2}{2} - n \rangle \) corresponds to the factor \( q^{-\frac{n^2}{2} - n} \) in (1.1). The homological degree shift \([n/2, n/2]\) is added to make \( r1_n \) commute with the 1-morphisms in \( \mathcal{U} \) up to homotopy equivalence (see Theorem 1.1). We use the convention that the Euler characteristic is not affected by a global homological shift.

The bicomplex \( r^{-1}1_n \) is given by inverting all arrows in (1.2), rotating diagrams representing differentials by 180 degree, and replacing \( C_{k,l} \) with

\[
C_{k,l}^L := F^{(k)} E^{(k)} 1_n(kn+k) \otimes \Lambda^l \tilde{W}_k, \quad \tilde{W}_k = \text{Span}_Z \{w_1, \ldots, w_k\},
\]

where \( \deg(w_j) = 2j \). Finally, we have

\[
r^{-1}1_n := C_{\bullet, \bullet} \begin{pmatrix} \frac{n^2}{2} + n \end{pmatrix} [-n/2, -n/2].
\]

\[\text{1The index } L \text{ stays here for the left adjoint.}\]
It is an easy check that the Euler characteristics of \( r \mathbf{1}_n \) and \( r^{-1} \mathbf{1}_n \) in \( \text{Kom}(\hat{\mathcal{U}}) \) coincide with \( r \mathbf{1}_n \) and \( r^{-1} \mathbf{1}_n \), respectively.

Let us list some properties of these bicomplexes, which follow directly from the definition.

- For each \( k \), the horizontal complex \( C_{k,\bullet} = \bigoplus_{l \in \mathbb{Z}} C_{k,l} \) forms a \( k \)-dimensional cube and hence is bounded.
- The total complex \( \text{Tot}(C_{\bullet,\bullet}) \) is a well-defined complex in \( \hat{\mathcal{U}} \), i.e., for each integer \( p \), \( \bigoplus_{k+l=p} C_{k,l} \in \text{Ob}(\hat{\mathcal{U}}) \) is a finite direct sum.
- The horizontal differentials are given by certain central elements in \( \text{End}(\mathcal{F}^{(k)}\mathcal{E}^{(k)} \mathbf{1}_n) \) defined in Section 3 and generated by dots.

Recall that \( \hat{\mathcal{U}} \) is the Karoubi envelope of the 2-category \( \mathcal{U} \) defined in [12]. The generators for 1-morphisms in \( \mathcal{U} \) are \( \mathcal{E}\mathbf{1}_n(t) \) and \( \mathcal{F}\mathbf{1}_n(t) \) for \( n, t \in \mathbb{Z} \). The involutive 2-functors \( \omega, \sigma \) and \( \psi \), generating the symmetry group \( \mathcal{G} = (\mathbb{Z}/2\mathbb{Z})^3 \) of \( \mathcal{U} \) were also introduced in [12] and [2]. We recall these definitions and extend them to \( \hat{\mathcal{U}} \) in Section 10. Let us denote by \( \mathcal{G}_1 := \{1, \sigma \omega \} \) the subgroup of \( \mathcal{G} \).

Throughout this paper, we adopt the notation \( rr^{-1} \mathbf{1}_n \) for the tensor product of two complexes, i.e., we omit tensor sign, since on 1-morphisms of \( \hat{\mathcal{U}} \) tensor product is just a concatenation.

Our main result is the following:

**Theorem 1.1** (Centrality) For any complex \( X \in \text{Com}(\mathcal{U}) \), there are isomorphisms

\[
\kappa_X : Xr \mathbf{1}_n \rightarrow rX \mathbf{1}_n, \quad \eta_X : Xr^{-1} \mathbf{1}_n \rightarrow r^{-1}X \mathbf{1}_n
\]

of bicomplexes in \( \text{Com}(\hat{\mathcal{U}}) \).

(Invertibility) The bicomplexes \( rr^{-1} \mathbf{1}_n \) and \( r^{-1}r \mathbf{1}_n \) in \( \text{Kom}(\hat{\mathcal{U}}) \) are homotopy equivalent to \( \mathbf{1}_n \).

(Symmetry) The bicomplexes \( r \mathbf{1}_n \) and \( r^{-1} \mathbf{1}_n \) in \( \text{Kom}(\hat{\mathcal{U}}) \) are invariant under the action of \( \mathcal{G}_1 \subset \mathcal{G} \). Moreover, \( r^{-1} \mathbf{1}_n = \sigma \omega \psi (r \mathbf{1}_n) \) is isomorphic to \( \psi (r \mathbf{1}_n) \).

Note that since the bicomplexes \( r \mathbf{1}_n \) and \( r^{-1} \mathbf{1}_n \) are bounded from above and below respectively, and \( \mathcal{U} \) does not admit infinite direct sums, their tensor product \( rr^{-1} \mathbf{1}_n \) does not belong to \( \text{Kom}(\hat{\mathcal{U}}) \). Instead we are using \( \text{Kom}(\hat{\mathcal{U}}) \) which is the inverse limit of the categories of bounded bicomplexes \( \text{Kom}^b(\mathcal{U}_N) \), where \( \mathcal{U}_N \) is the Schur quotient of \( \mathcal{U} \) defined by setting \( 1_{N+2} = 0 \) (see Section 12 for more details).

Properties listed in Theorem 1.1 are natural lifts of the properties of the ribbon element to higher categorical level. We would also expect the following to hold.

**Conjecture 1.2** (Naturality) The chain maps \( \kappa_X \) and \( \eta_X \) are natural, i.e., they commute with all 2-morphisms of \( \hat{\mathcal{U}} \).

(Decomposability) For \( n \geq 0 \) the bicomplex \( r \mathbf{1}_n \) is indecomposable in \( \text{Kom}(\hat{\mathcal{U}}) \), and the bicomplex \( \omega(r \mathbf{1}_{-n}) \) is isomorphic to a direct sum of \( r \mathbf{1}_n \) and a contractible complex. For \( n \leq 0 \) the bicomplex \( \omega(r \mathbf{1}_{-n}) \) is indecomposable in \( \text{Kom}(\hat{\mathcal{U}}) \), and the bicomplex \( r \mathbf{1}_n \) is isomorphic to a direct sum of \( \omega(r \mathbf{1}_{-n}) \) and a contractible complex. For \( n = 0 \), the bicomplexes \( r \mathbf{1}_n \) and \( \omega(r \mathbf{1}_{-n}) \) are isomorphic.

Observe that we could use \( \sigma(r \mathbf{1}_{-n}) \) instead of \( \omega(r \mathbf{1}_{-n}) \), since by Theorem 1.1 they are isomorphic.
Let us comment on this conjecture. We expect the isomorphisms $\kappa_X$ and $\eta_X$ to be natural, and hence, to be defined for any $X \in \text{Com}(\hat{U})$. This would imply that the bicomplexes $r_1^n$ and $r^{-1}_1^n$ belong to the Drinfeld center of $\text{Com}(\hat{U})$ viewed as an additive monoidal category. Here we regard 1-morphisms in $\text{Com}(\hat{U})$ as objects of the monoidal category. The monoidal structure is given by composition of 1-morphisms and horizontal composition of 2-morphisms. The collection of chain maps $\kappa_X$ define then an invertible natural transformation $\kappa : -r \Rightarrow r$ between endofunctors of $\text{Com}(\hat{U})$ given by tensoring on the left and on the right with the complex $r_1^n$ for an appropriate $n$.

The first column of our bicomplex $C_0^n \rightarrow C_1^n \rightarrow C_2^n \rightarrow \ldots$ is an example of so-called Rickard complex introduced by Chuang and Rouquier in [6] and intensively studied by Cautis and Kamnitzer [4, 5]. The Rickard-Rouquier complex $1^{-n}T^1_n$ categorifies the action of the Weyl group on the finite-dimensional representations and satisfies the braid relation. It can be defined as follows:

\[
T^1_n : \ldots \rightarrow \mathcal{F}((n+s) \langle s \rangle)1_n \rightarrow \mathcal{F}(n+s-1)\mathcal{E}(s-1)1_n \rightarrow \ldots \rightarrow \mathcal{F}(n)1_n
\]

for $n \geq 0$, \hspace{1cm} (1.3)

\[
T^1_n : \ldots \rightarrow \mathcal{E}((n+s) \langle s \rangle)1_n \rightarrow \mathcal{E}(n+s-1)\mathcal{F}(s-1)1_n \rightarrow \ldots \rightarrow \mathcal{E}(n)1_n
\]

for $n \leq 0$, \hspace{1cm} (1.4)

where the differential are non-zero maps.

**Conjecture 1.3** The total complex of the ribbon bicomplex $\text{Tot}(r^{-1}1_n)$ is homotopy equivalent to

\[
T^2 1_n \left(\frac{n^2}{2} + n\right) [-n/2, -n/2].
\]

Note that the decategorified version of this conjecture holds. For $n \geq 0$, the Euler characteristic

\[
T^2 1_n = T 1_{-n} T 1_n = \sum_{l,s \geq 0} (-q)^{l+s} E^{(n+s)} F^{(s)} F^{(n+l)} E^{(l)} 1_n
\]

\[
= \sum_{k=0}^{\infty} (-1)^k q^{kn+k} (q^2; q^2)_k F^{(k)} E^{(k)} 1_n
\]

coincides with $r^{-1}1_n$ after multiplying with $q^{n^2/2+n}$. The case $n \leq 0$ can be obtained similarly, after replacing $n$ by $-n$ and exchanging $E$’s and $F$’s.

**1.1 Strategy of the Proof of Theorem 1.1**

It is enough to check centrality on the generators. This is because any “chain group” of $X$ is a composition of $\mathcal{E}$’s and $\mathcal{F}$’s and the maps $\eta_\mathcal{E}$ and $\eta_\mathcal{F}$ are adjoint to $\kappa_\mathcal{F}$ and $\kappa_\mathcal{E}$, respectively.

**Lemma 1.4** There are maps

\[
\kappa_\mathcal{E} : r\mathcal{E}1_n \rightarrow r\mathcal{E}1_n, \hspace{1cm} \kappa_\mathcal{F} : r\mathcal{F}1_{n+2} \rightarrow r\mathcal{F}1_{n+2}
\]

which are homotopy equivalences in $\text{Kom}(\hat{U})$.

Here $r\mathcal{E}1_n$ is the bicomplex obtained by composing $r1_{n+2}$ to the left of $\mathcal{E}1_n$. The differentials are those of $r1_{n+2}$ extended by identity on $\mathcal{E}1_n$. The other bicomplexes are defined analogously.
To construct $\kappa_\mathcal{E}$, we will proceed as follows. We will define an intermediate bicomplex $(r\mathcal{E}1_n)'$ as an indecomposable summand of $r\mathcal{E}1_n$, whose “chain groups” are

$$C^i_{k,l} = \mathcal{F}(k)\mathcal{E}(k+1)1_n(-kn - 2k) \otimes \Lambda^i W'_k$$

with $W'_k := \text{Span}_\mathbb{Z}(w_2, \ldots, w_{k+1})$, the total $q$-degree shift $(-\frac{q^2}{2} - 3n - 4)$ and the homological shift $[n/2 + 1, n/2 + 1]$. Then we show that $\mathcal{E}r1_n$ and $r\mathcal{E}1_n$ retract to $(r\mathcal{E}1_n)'$ (Theorems 7.1, 5.3). Composing the corresponding homotopy equivalences we will get $\kappa_\mathcal{E}$. The construction of the chain maps between $\mathcal{E}r1_n$, $r\mathcal{E}1_n$ and $(r\mathcal{E}1_n)'$, and the proofs of Theorems 7.1 and 5.3 are the most involved technical part of the paper.

To define $\kappa_\mathcal{F}$, we use the invariance of $r1_n$ under $\sigma_\omega$. Indeed, we have

$$\sigma_\omega(\kappa_\mathcal{E}) : \sigma_\omega(\mathcal{E}r1_n) \to \sigma_\omega(r\mathcal{E}1_n).$$

However, $\sigma_\omega(\mathcal{E}r1_n) = \sigma_\omega(r)\mathcal{F}1_{n+2} \simeq r\mathcal{F}1_{n+2}$ and similarly, $\sigma_\omega(r\mathcal{E}1_n)$ is isomorphic to $\mathcal{F}r1_{n+2}$.

The proof of invertibility is based on the next theorem computing the action of the ribbon complex on the category of complexes over $\text{Flag}_N$ defined in [12] and the main result of [3]. Let us define the endofunctors $r^L_N$ and $r^R_N$ of $\text{Com}(\text{Flag}_N)$ on the left and right, respectively, i.e., $r^L_N(X) = \Gamma_N(r1_n)X$. Analogously, the endofunctors $(r^{-1})^L_N$ and $(r^{-1})^R_N$ are defined by tensoring with $\Gamma_N(r^{-1}1_n)$.

**Theorem 1.5** For any natural number $N$, $r^L_N$ and $r^R_N$ are the identity endofunctors of $\text{Com}(\text{Flag}_N)$ up to degree shift. Their inverses are $(r^{-1})^L_N$ and $(r^{-1})^R_N$, respectively.

The main result of [3] says that $\mathcal{U}$ is the inverse limit of $\text{Flag}$ 2-categories. Hence, we conclude that tensoring with $r^\pm 1 r^\mp 11_n$ is the inverse limit of the identity endofunctor in $\text{Flag}_N^*$, which is the identity endofunctor of $\text{Com}(\mathcal{U})$.

To prove symmetry, we construct a bicomplex $\tilde{r}1_n$ which is (1) isomorphic to $r1_n$, in $\text{Kom}(\mathcal{U})$ and (2) invariant under $\sigma_\omega$. This is done in Section 11. Then, given the isomorphism $H : r1_n \to \tilde{r}1_n$, the composition $\sigma_\omega(H^{-1}) \circ H : r1_n \to \sigma_\omega(r1_n)$ is the required isomorphism.

The paper is organized as follows. After some preliminaries, we define the central elements $c_{ij}$ indexed by partitions, $r1_n$, $r^{-1}1_n$ and the intermediate bicomplex $(r\mathcal{E}1_n)'$. The next four sections are devoted to the definition of the chain maps and homotopies and to the proofs of Theorems 7.1, 5.3 and Theorem 1.1 (Centrality). After that we recall the definitions of the symmetry 2-functors and define the images of $r1_n$ under those symmetries. Section 11 is devoted to the construction of $\tilde{r}1_n$. In the last section, we prove Theorem 1.5 and Theorem 1.1 (Invertibility).

In Appendix, we collect identities needed for the proofs.

## 2 General Facts

### 2.1 Definitions and Conventions

We refer to [12] and [11] for the definitions of the 2-categories $\mathcal{U}$ and its Karoubi envelope $\mathcal{U}$. The 2-morphisms in these 2-categories are given by diagrams modulo some local relations. The right most region in all our diagrams is labeled by $n$. For any 1-morphism $x \in \text{Hom}_{\mathcal{U}}(n, m)$, we denote by $\text{Dot}(x) \subset \text{End}_{\mathcal{U}}(x)$ the subspace of its 2-endomorphisms generated by dots. A thick line labeled with a positive integer $k$ denotes the identity
2-morphism of $\mathcal{E}(k) := (\mathcal{E}^k, \langle \frac{k(k-1)}{2} \rangle)$ if it is oriented upwards; and the identity 2-morphism of $\mathcal{F}(k) := (\mathcal{F}^k, \langle \frac{k(k-1)}{2} \rangle)$ in $\mathcal{U}$ otherwise, where $\langle \cdot \rangle$ is the idempotent defined in [11] and $\langle \cdot \rangle$ is its image under 180-degree rotation. The case $k = 1$ will be represented by a thin line without any label for a better visibility.

In this paper, for any 2-category $\mathcal{C}$, we denote by Kom$(\mathcal{C})$ the 2-category of bicomplexes over the 2-category $\mathcal{C}$. The objects of Kom$(\mathcal{C})$ coincide with objects of $\mathcal{C}$, 1-morphisms are bicomplexes of 1-morphisms in $\mathcal{C}$, and 2-morphisms are chain maps, constructed from 2-morphisms in $\mathcal{C}$. Let Com$(\mathcal{C})$ be the 2-category with the same objects and 1-morphisms as Kom$(\mathcal{C})$ but whose 2-morphisms are chain maps up to homotopy. We will denote by Kom$^b(\mathcal{C})$ and Kom$^b(\mathcal{C})$ corresponding bounded versions.

The degree of a 2-morphism in $\mathcal{U}$ is defined as degree of the target minus degree of the source plus degree of the diagram.

### 2.2 Strong Deformation Retraction

Let us recall the definitions.

A chain complex $(C', d')$ is a strong deformation retract of a chain complex $(C, d)$ if there exist

- A chain map $f : C \to C'$, i.e., $d'f = fd$;
- A chain map $g : C' \to C$, i.e., $dg = gd'$;
- A homotopy $h : C_{\bullet} \to C_{\bullet-1}$ satisfying $hd + dh = 1 - gf$ and

\[
\begin{align*}
fg &= 1 \\
h^2 &= 0 \\
fh &= 0 \\
hg &= 0.
\end{align*}
\]

From the above four equalities including $g$, it is enough to show that $fg = 1$ and $hG + dh = 1 - gf$. The other two equalities $(dg = gd', hg = 0)$ follow from them.

Let $(C, d^V, d^H)$ and $(C', d'^V, d'^H)$ be two bicomplexes. We say that the second bicomplex is a strong deformation retract of the first one if there exist

- A chain map $f : C \to C'$ with $d'^Hf = fd^H, d'^Vf = fd^V$;
- A chain map $g : C' \to C$ with $d^Hg = gd^H, d^Vg = gd^V$;
- A homotopy $h = h^H + h^V : C_{\bullet} \to C_{\bullet-1}$ with $h^Hd^H + h^Vd^V + d^Hh^H + d^Vh^V = 1 - gf, h^Hd^V + d^Vh^H = 0$ and $h^Vd^H + d^Hh^V = 0$ satisfying

\[
\begin{align*}
fg &= 1 \\
h^Hh^V &= 0 \\
h^Hh^H + h^Vh^H &= 0 \\
h^Vh^V &= 0 \\
f^Hh^0 &= 0 \\
f^Vh^0 &= 0 \\
h^Hg &= 0 \\
h^Vg &= 0.
\end{align*}
\]

Remark The equalities $d^Hg = gd'^H, d^Vg = gd'^V, h^Hg = 0$ and $h^Vg = 0$ follow from the others.

### 2.3 Symmetric Functions

Let us denote by $S_k$ the symmetric group and $A_k = \mathbb{Z}[x_1, \ldots, x_k]^{S_k}$ the ring of symmetric polynomials. Let $A$ be the ring of symmetric functions, defined as the inverse limit of the system $(A_k)_{k \in \mathbb{N}}$.

For a partition $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_a)$ with $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_a \geq 0$ let $|\lambda| := \sum_{i=1}^{a} \lambda_i$. We denote by $P(a)$ the set of all partitions $\lambda$ with at most $a$ parts (i.e., with $\lambda_{a+1} = 0$). Moreover, the set of all partitions (i.e., the set $P(\infty)$) we denote simply by $P$.

The dual (conjugate) partition of $\lambda$ is the partition $\lambda' = (\lambda_1', \lambda_2', \ldots)$ with $\lambda_j' = \sharp\{i \mid \lambda_i \geq j\}$ which is given by reflecting the Young diagram of $\lambda$ along the diagonal.
The Schur polynomials \(\{s_\lambda \mid \lambda \in P(k)\}\) form a basis of \(A_k\), as well as Schur functions \(\{s_\lambda \mid \lambda \in P\}\) is a base of \(A\). The multiplication in this basis is given by the following formula

\[
s_\mu s_\nu = \sum_{\lambda \in P} N_{\mu \lambda}^{\nu} s_\lambda,
\]

where \(N_{\mu \lambda}^{\nu}\) are the Littlewood-Richardson coefficients. The elementary symmetric functions \(\{s_d = e_d \mid d \in \mathbb{N}\}\) or the complete symmetric functions \(\{s_d = h_d \mid d \in \mathbb{N}\}\) generate \(A\) multiplicatively.

The ring \(A\) has a natural Hopf algebra structure with comultiplication

\[
\Delta : A \rightarrow A \otimes A
\]

given by

\[
\Delta(s_\lambda) = \sum_{\mu, \nu \in P} N_{\mu \nu}^{\lambda} s_\mu \otimes s_\nu,
\]

and with counit and antipode defined as follows

\[
\epsilon : A \rightarrow \mathbb{Z} \quad \gamma : A \rightarrow A
\]

\[
s_\lambda \mapsto \delta_{\lambda,0}, \quad s_\lambda \mapsto (-1)^{|\lambda|} s_{\lambda^t}.
\]

3 The Center of the 2-category \(\mathcal{U}\)

After recalling the general definition of a center for any linear category, we construct central elements in \(\mathcal{U}(n, m)\).

3.1 Center of a Category

For a linear category \(\mathcal{C}\), the center \(Z(\mathcal{C})\) of \(\mathcal{C}\) is the ring of endo-natural transformations on the identity functor \(\mathcal{C} \xrightarrow{1} \mathcal{C}\). Thus, an element \(\sigma\) of \(Z(\mathcal{C})\) is a collection of endomorphisms \(\sigma_x : x \rightarrow x\) for objects \(x\) in \(\mathcal{C}\) such that we have

\[
f \sigma_x = \sigma_y f
\]

for any morphisms \(f : x \rightarrow y\) in \(\mathcal{C}\). Multiplication of two elements \(\sigma\) and \(\tau\) in \(Z(\mathcal{C})\) is defined by

\[
(\tau \sigma)_x := \tau_x \sigma_x.
\]

It is easily seen that \(Z(\mathcal{C})\) is commutative. We call \(\sigma\) a central element of \(\mathcal{C}\).

Let \(\mathcal{C}\) be a linear 2-category. For each pair \((x, y)\) of objects in \(\mathcal{C}\), one can consider the center \(Z(\mathcal{C}(x, y))\) of the category \(\mathcal{C}(x, y)\) whose objects are the 1-morphisms between \(x\) and \(y\) and morphisms are 2-morphisms. The center \(Z(\mathcal{C}(x, y))\) is a commutative ring.

3.2 Central Elements in \(\mathcal{U}\)

We have natural ring homomorphisms

\[
d_a : A_a \rightarrow \text{Dot}(\mathcal{C}(a) \mathbf{1}_n),
\]

\[
d'_a : A_a \rightarrow \text{Dot}(\mathcal{F}(a) \mathbf{1}_n)
\]
that lift to

\[
d_a : A \to \text{Dot}(E^{(a)}1_n), \\
d'_a : A \to \text{Dot}(F^{(a)}1_n)
\]

by sending elementary symmetric functions of degree higher than \(a\) to zero.

In this subsection, for each 1-morphism \(f: n \to m\) in \(\mathcal{U}\), we define a ring homomorphism

\[
c = c_f : A \to \text{Dot}(f).
\]

For \(f = E^{(a)}1_n\), we set

\[
c_{E^{(a)}1_n}(x) = d_a(x).
\]

For \(f = F^{(a)}1_n\), we set

\[
c_{F^{(a)}1_n}(x) = d'_a(y(x)).
\]

For \(f = f_1 f_2 \ldots f_p\), where each \(f_j\) is \(E^{(aj)}1_{nj}\) or \(F^{(aj)}1_{nj}\), \(a_j \geq 0, n_j \in \mathbb{Z}\), we set

\[
c_{f_1 f_2 \ldots f_p}(x) = \text{horizontal composition}\left((c_{f_1} \otimes \ldots \otimes c_{f_p}) \Delta^{[p]}(x)\right)
\]

\[
= \sum c_{f_1}(x(1)) \circ \ldots \circ c_{f_p}(x(p)),
\]

where \(\Delta^{[p]} : A \to A^{\otimes p}\) is the \(p\)-output comultiplication with

\[
\Delta^{[p]}(x) = \sum x(1) \otimes \ldots \otimes x(p).
\]

Finally, for a direct sum \(f = f_1 \oplus \ldots \oplus f_p\), we set

\[
c_{f_1 \oplus \ldots \oplus f_p}(x) = \text{diag}(c_{f_1}(x), \ldots, c_{f_p}(x)).
\]

We also adopt the notation \((c_\lambda) f\) for \(c_f(s_\lambda)\) and draw

\[
(c_\lambda) f = \begin{array}{c}
c_\lambda \\
a_1 \\
\vdots \\
a_p
\end{array},
\]

where \(f = f_1 f_2 \ldots f_p\), each \(f_j\) is \(E^{(aj)}1_{nj}\) or \(F^{(aj)}1_{nj}\).

For \(f = E^a 1_n\) and \(f = F^a 1_n\), we have

\[
\begin{array}{c}
c_\lambda \\
\Delta^{[a]}(s_\lambda)
\end{array} := \begin{array}{c}
\Delta^{[a]}(s_\lambda)
\end{array}, \quad \text{and} \quad \begin{array}{c}
c_\lambda \\
\Delta^{[a]}(s_\lambda)
\end{array} := (-1)^{|a|} \begin{array}{c}
\Delta^{[a]}(s_\lambda)
\end{array}.
\]

For \(f = E^{(a)}1_n\) and \(f = F^{(a)}1_n\), we have

\[
c_a \begin{array}{c}
a
\end{array} = A, \quad \begin{array}{c}
c_a \begin{array}{c}
a
\end{array}
\end{array} = (-1)^{|a|} \begin{array}{c}
a
\end{array}.
\]

The following proposition is the direct consequence of the definitions.

**Proposition 3.1** For 1-morphisms \(f: n \to l\) and \(g: l \to m\) in \(\mathcal{U}\), we have

\[
(c_\lambda)_{gf} = \sum_{\mu, v \in P} N^{\mu}_{\mu, v} (c_\mu)_g \circ (c_v)_f
\]

\[
\begin{array}{c}
c_\lambda
\end{array} = \begin{array}{c}
N^{\mu}_{\mu, v} (c_\mu)_g \circ (c_v)_f
\end{array}.
\]

\[
\begin{array}{c}
c_\lambda
\end{array} = \begin{array}{c}
A
\end{array}.
\]
and

$$(c_{\lambda} c_{\mu})_{gf} = \sum_{v \in P} N_{\lambda, \mu}^v (c_v)_{gf}.$$ 

In particular, for $\lambda \in P_d$, and $f = \mathcal{E}^{(i_1)} \mathcal{F}^{(j_1)} \ldots \mathcal{E}^{(i_p)} \mathcal{F}^{(j_p)} I_n$, we have

$$(c_{\lambda})_{\mathcal{E}^{(i_1)} \mathcal{F}^{(j_1)} \ldots \mathcal{E}^{(i_p)} \mathcal{F}^{(j_p)} I_n} = \sum_{\lambda^{(1)}, \mu^{(1)}, \ldots, \lambda^{(p)}, \mu^{(p)} \in P} \mathcal{N}_+^{\lambda^{(1)}, \ldots, \lambda^{(p)}, \mu^{(1)}, \ldots, \mu^{(p)}} \cdot (\lambda^{(1)})^{(1)} \circ \ldots \circ (\lambda^{(p)})^{(1)} \circ (\mu^{(1)})^{(1)} \circ \ldots \circ (\mu^{(p)})^{(1)},$$

where $\mathcal{N}_+^{\lambda^{(1)}, \ldots, \lambda^{(p)}, \mu^{(1)}, \ldots, \mu^{(p)}} \in \mathbb{Z}_{\geq 0}$ are the Littlewood–Richardson coefficients.

\textbf{Examples}

1) $(c_d)_{n} = \sum_{k \geq 0} d'_{b_k} (\gamma(h^i)) \circ d_{a_k} (h^j) = \sum_{k \geq 0} (-1)^k (e_{l_1} \cdots e_{l_n})$

2) $\alpha(c_{\lambda})_{f} = (c_{\lambda})_{g \alpha}$

Similarly, we have

Proposition 3.2 For $m, n \in \mathbb{Z}$, $\lambda \in P$ we have $c_{\lambda} \in Z(\mathcal{U}(n, m))$.

Proof We need to prove that for every 2-morphism $\alpha : f \rightarrow g$ in $\mathcal{U}(n, m)$ we have

$\alpha(c_{\lambda}) = (c_{\lambda}) \alpha$.

Splitting the thick lines and moving the dots as follows

we see that it is enough to prove the proposition for 2-morphisms of $\mathcal{U}$, generated by dots, crossings and turns. For dots, the proposition is clear.

Since elementary functions generate $A$, it is enough to consider $c_{\lambda}$ for $\lambda = 1^d$, $d \in \mathbb{N}$ in what follows. Note that $(c_{1^d})_{\mathcal{E}^2 I_n} \neq 0$ only for $d = 1$ or $d = 2$ and

$$c_{(1)} = \bullet \quad + \quad \bullet, \quad c_{(1,1)} = \bullet \quad \bullet.$$ 

Using the NilHecke relations, we can easily check that both upper 2-morphisms commute with the crossing. The same is true for downward oriented arrows.

Similarly, we have

$$c_{1^d} = \bullet \quad \bullet \quad \bullet \quad \bullet.$$
We see that by multiplying with the turn from below, we get 0, which coincides with \((c_1d)_n = 0\). The other turns can be proved similarly.

\[\newpage\]

4 Definitions of \(r_1n, r^{-1}1_n\) and \((rE1_n)\)

4.1 Ribbon Bicomplex

As it was already mentioned in Section 1, the bicomplex \(r1_n\) categorifying the ribbon element has “chain groups”

\[C_{k,l} := \mathcal{E}(k)E(k)1_n\mathcal{F}(k)E(k)1_n(kn - k) \otimes \Lambda^k W_k, \quad W_k = \text{Span}_\mathbb{Z}\{w_1, \ldots, w_k\}, \quad \deg(w_j) = -2j\]

with the total \(q\)-degree shift \((-\frac{n^2}{2} - n)\) and homological shift \([n/2, n/2]\). Here note that for an additive category \(\tilde{C}\) and a free abelian group \(G\) of finite rank, one can construct a functor \(- \otimes G : \tilde{C} \to \tilde{C}\).

The horizontal differential \(d^H_{k,l} : C_{k,l} \to C_{k,l+1}\) sends \(x \mapsto c \wedge x\), where

\[c := \sum_{j=1}^k c_j \otimes w_j := \sum_{j=1}^k (-1)^j \begin{vmatrix} c_j \end{vmatrix} \otimes w_j \in \text{Dot}(\mathcal{E}(k)E(k)1_n) \otimes W_k\]

are our central elements.

To define the vertical differential, we proceed as follows. Consider the linear map

\[\alpha_k : \Lambda^k W_k \to \text{Dot}(\mathcal{E}(k)E(k)1_n) \otimes \Lambda^k W_k+1\]

where \(1\) denotes the identity 2-morphism of \(\mathcal{E}(k)1_n\). This map induces an algebra homomorphism \(\alpha_k : \Lambda^k W_k \to \text{Dot}(\mathcal{E}(k)E(k)1_n) \otimes \Lambda^k W_k+1\) and let \(\alpha_{k,l} : \Lambda^l W_k \to \text{Dot}(\mathcal{E}(k)E(k)1_n) \otimes \Lambda^l W_k+1\) be its degree \(l\) part. Then the vertical differential is

\[d^V_{k,l} := (-1)^l \begin{vmatrix} \alpha_{k,l} \end{vmatrix} : C_{k,l} \to C_{k+1,l}, \quad \text{where}\]

\[\alpha_{k,l}(w_{i_1} \wedge w_{i_2} \wedge \cdots \wedge w_{i_l}) = \alpha_k(w_{i_1}) \wedge \alpha_k(w_{i_2}) \wedge \cdots \wedge \alpha_k(w_{i_l})\]

\[= 1 \otimes w_{i_1} \wedge \cdots \wedge w_{i_l} - \sum_{j=1}^l (-1)^{k+1-i+j-l-j} \begin{vmatrix} e_{k+1-i-j} \end{vmatrix} \otimes (w_{i_1} \wedge \cdots \wedge w_{i_j} \wedge \cdots \wedge w_{i_l}) \wedge w_{i_{l+1}}.\]  

(4.1)

In what follows to simplify the notation, we will often omit the tensor sign between the graphical part and \(\Lambda^l W_k\). Also, we will sometimes use a bullet labeled with a symmetric function instead of a box.
Proposition 4.1 \( r1_n \) as defined above is a bicomplex, i.e.,

\[
d^H \circ d^H = 0 \quad d^V \circ d^H + d^H \circ d^V = 0 \quad d^V \circ d^V = 0.
\]

Before giving the proof, let us show how the beginning of this bicomplex looks like (see Fig. 1).

Proof The first formula \((d^H)^2 = 0\) is immediate from the definition, since \(c \wedge c = 0\).

For the next equation we have to check that the following square anticommutes:

\[
\begin{array}{c}
C_{k,l} \\
\downarrow d_k^V \\
\downarrow d_{k+1,l}^V \\
C_{k+1,l}
\end{array}
\xrightarrow{c \wedge} \begin{array}{c}
C_{k,l+1} \\
\downarrow d_{k+1}^V \\
\downarrow d_{k+1,l+1}^V \\
C_{k+1,l+1}
\end{array}
\]

After moving all \(c_j\) down, by using their centrality, the anticommutativity reduces to

\[
\sum_{i_0=1}^{k+1} w_{i_0} \wedge d_k^V c_{i_0} + \sum_{i_0=1}^{k} d_k^V c_{i_0} \wedge w_{i_0} c_{i_0} = 0
\]

or to the following identity in \(\text{Dot}(\mathcal{F}^{(k)} \mathcal{E}^{(k)} 1_n) A^l W_k\)

\[
\sum_{i_0=1}^{k+1} c_{i_0} w_{i_0} \wedge w_{i_1} \wedge \cdots \wedge w_i \\
- \sum_{j=0}^{l} (-1)^{k+1-i_j+l-j} \sum_{i_0=1}^{k} c_{i_0} (e_{k+1-i_j}^1)^2 w_{i_0} \wedge \cdots \hat{w}_{i_j} \cdots \wedge w_i \wedge w_{k+1} \\
= \sum_{i_0=1}^{k+1} c_{i_0} w_{i_0} \wedge w_{i_1} \wedge \cdots \wedge w_i \\
- \sum_{j=1}^{l} (-1)^{k+1-i_j+l-j} \sum_{i_0=1}^{k} c_{i_0} (e_{k+1-i_j}^1)^2 w_{i_0} \wedge \cdots \hat{w}_{i_j} \cdots \wedge w_i \wedge w_{k+1},
\]

where the lower index 2 indicates the stand where this endomorphism acts. This is easily seen to hold after accomplishing the second summand for \(j = 0\) to zero by means of the formula

\[
\sum_{i_0=1}^{k+1} (-1)^{k+1-i_0} c_{i_0} (e_{k+1-i_0}^1)^2 = 0 \in \text{Dot}(\mathcal{F}^{(k)} \mathcal{E}^{(k)} 1_n) \tag{4.2}
\]

or pictorially

\[
\sum_{i=1}^{k+1} (-1)^{k+1-i} \rightarrow^c e_{k+1-i}^1 \rightarrow^k \sum_{i=1}^{k} c_i = 0.
\]

The formula (4.2) follows from the fact that \(e_{k+1} \in \text{Dot}(\mathcal{E}^{(k)} 1_n)\) (or \(e_{k+1} \in \text{Dot}(\mathcal{F}^{(k)} 1_n)\)) is zero and

\[
\begin{aligned}
\sum_{j=0}^{d} (-1)^{d-j} c_j (e_{d-j}^1)^2 &= \sum_{j=0}^{d} (-1)^{d-j} \sum_{l=0}^{d-j} (-1)^{d-j-l} (e_j^1)^1 (e_{d-j-l}^1)^2 (h_l)^2 \\
&= (c_d) 1 \in \text{Dot}(\mathcal{F}^{(d)} \mathcal{E}^{(d)} 1_n) \tag{4.3}
\end{aligned}
\]
for any $d$, $r$, and $s$, since $\sum_{i=0}^{p}(-1)^i e_i h_{p-i} = 0$ for any $p > 0$. Here $(c_d)_1 = (c_d)_{\mathcal{F}(r)}$ is equal to $(-1)^d e_d$ sitting on the first strand.

The proof of $d^V_{k+1,1} \circ d^V_{k,1} = 0$ is based on the following identities

$$
\includegraphics{diagram}
$$

Let us explain this in more details. The formula (4.1) contains one summand without dots, let us call it $A$, and the other summands called $B$. Putting $A$ on top of $d^V_{k-1,1}$ is zero by the first identity printed above. Now any square resulting from putting $B$ on top of $d^V_{k-1,1}$ gives rise to the second identity with $t = k - i_j$ and $s = k - i_j'$ or $s = 0$.

The first identity can be proved as follows. By using the associativity of the trivalent vertices in the thick calculus ([11, Proposition 2.4]), we can attach the second horizontal line to the first one

$$
\includegraphics{diagram}
$$

and then apply [11, Eq. (2.70)]. The proof of the second identity is similar after sliding $e_{t+1}$ and $e_{s+1}$ down by using the comultiplication rule in the ring of symmetric polynomials (or [11, Eq. (2.67)]).

4.2 The Inverse Bicomplex

The bicomplex $r^{-1}1_n$ is defined as a kind of “left adjoint” of $r1_n$. It has the form

$$
\begin{array}{cccccccc}
C^L_{00} & C^L_{10} & C^L_{20} & \cdots & C^L_{k0} \\
\uparrow & \uparrow & \uparrow & \cdots & \uparrow \\
(d^V_{00})^L & (d^H_{10})^L & (d^V_{20})^L & \cdots & (d^V_{k0})^L \\
C^L_{01} & C^L_{11} & C^L_{21} & \cdots & C^L_{k1} \\
\uparrow & \uparrow & \uparrow & \cdots & \uparrow \\
(d^V_{01})^L & (d^H_{11})^L & (d^V_{21})^L & \cdots & (d^V_{k1})^L \\
C^L_{02} & C^L_{12} & C^L_{22} & \cdots & C^L_{k2} \\
\uparrow & \uparrow & \uparrow & \cdots & \uparrow \\
(d^V_{02})^L & (d^H_{12})^L & (d^V_{22})^L & \cdots & (d^V_{k2})^L \\
C^L_{03} & C^L_{13} & C^L_{23} & \cdots & C^L_{k3} \\
\uparrow & \uparrow & \uparrow & \cdots & \uparrow \\
(d^V_{03})^L & (d^H_{13})^L & (d^V_{23})^L & \cdots & (d^V_{k3})^L \\
\vdots & \vdots & \vdots & \cdots & \vdots \\
\end{array}
$$

where

$$
C^L_{k,l} = \mathcal{F}(k) \mathcal{E}(k) 1_n (kn + k) \otimes A^l \tilde{W}_k = C^R_{k,l}
$$

with the total $q$-degree shift $\left(\frac{n^2}{2} + n\right)$ and the homological shift $[-n/2, -n/2]$. Here $\tilde{W}_k = \text{Span}_\mathbb{Z}\{\tilde{w}_1, \ldots, \tilde{w}_k\}$ and $\deg(\tilde{w}_j) = 2j$. 

 Springer
The differentials are obtained by rotating the original differentials by $\pi$. We have
\[(d^H_{k,l})^L : C^L_{k,l+1} \to C^L_{k,l},\]
\[\tilde{w}_{i_1} \wedge \cdots \wedge \tilde{w}_{i_{l+1}} \mapsto \sum_{j=1}^l (-1)^{j-1} c^L_j \otimes \tilde{w}_{i_1} \wedge \tilde{w}_{i_j} \wedge \tilde{w}_{i_{l+1}},\]
where $(c^L_d)_{E^{(k)}E^{(k)}_1} = \sum_{j=0}^d (-1)^j h_{d-j} \otimes e_j$. The vertical differential is
\[(d^V_{k,l})^L := (-1)^k \begin{array}{c}
\alpha_{k,l} \\
\otimes \\
\Lambda l W_k
\end{array} : C^L_{k+1,l} \to C^L_{k,l},\]
with $\alpha_{k,l}$ defined as before by (4.1).

### 4.3 Intermediate Bicomplex

Recall that $r E^{1}_n$ is the bicomplex obtained by composing $r E^{1}_{n+2}$ to the left of $E^{1}_n$. Its “chain groups” are $F^{(k)}E^{(k)}E^{1}_n(-kn-3k) \Lambda^l W_k$ with the total $q$-degree shift $(-\frac{q^2}{2} - 3n - 4)$ and homological shift $[n/2 + 1, n/2 + 1]$. We will denote them by $C_{k,l}E$. The differentials are those of $r E^{1}_{n+2}$ extended by identity on $E^{1}_n$. The Euler characteristic of $r E^{1}_n$ is
\[r E^{1}_n = q^{-\frac{n^2}{2} - 3n - 4} \sum_{k=0}^{\infty} (-1)^k q^{kn-2k} \left(q^{-4}; q^{-2}\right)_k^{F^{(k)}E^{(k)}_1} 1_n. \quad (4.4)\]

The intermediate bicomplex
\[(r E^{1}_n)^{\prime} = \left( \oplus_{k,l} C_{k,l}^{\prime}, d^H_{k,l}^{\prime}, d^V_{k,l}^{\prime} \right)\]
is an indecomposable summand of $r E^{1}_n$ defined as follows. The “chain groups” are
\[C_{k,l}^{\prime} = F^{(k)}E^{(k+1)}_1(-kn-2k) \Lambda^l W_k^{\prime}\]
with $W_k^{\prime} := \text{Span}_{Z}\{w_2, \ldots, w_{k+1}\}$ and the same total shifts as for $r E^{1}_n$.

The horizontal differential $d^H_{k,l}^{\prime}$ sends $x$ to $c^{\prime} \wedge x$ where
\[c^{\prime} := \sum_{j=2}^{k+1} \varepsilon_{j-1,1} w_{j}\]
\[:= \sum_{j=2}^{k+1} \left( \sum_{\lambda, \mu \subseteq \{j-1,1\}} (-1)^{|\lambda|} N^{(j-1,1)}_{\lambda, \mu} \left( \begin{array}{c} k \\ j-1 \end{array} \right) \right) w_j \in \text{Dot} \left( F^{(k)}E^{(k+1)}_1 W_k^{\prime} \right)\]
with $W_k^{\prime} := \text{Span}_{\mathbb{Z}}\{w_2, \ldots, w_{k+1}\}$ and the same total shifts as for $r E^{1}_n$.

The vertical differential $d^V_{k,l}^{\prime} : C_{k,l}^{\prime} \to C_{k+1,l}^{\prime}$ is defined as follows
\[(d^V_{k,l}^{\prime})^L := (-1)^k \begin{array}{c}
\alpha_{k,l}^{\prime} \\
\otimes \\
\Lambda l W_k^{\prime}
\end{array} ,\]
where
\[ \alpha'_{k,l} : A^l W_k \rightarrow \text{Dot} \left( \mathcal{E}^{(k+1)} W_{k+1} \right) \]
is defined similar to (4.1). For \( 1 < i_1 < i_2 < \cdots < i_l \leq k + 1 \), we have
\[
\alpha'_{k,l} \left( w_{i_1} \land w_{i_2} \land \cdots \land w_{i_l} \right) = w_{i_1} \land \cdots \land w_{i_l} - \sum_{j=1}^{l} (-1)^{k-j+l-j} \left( e_{k+1-j} \right) w_{i_j} \land \cdots \land w_{i_l} \land w_{k+2}.
\]

It can be verified similarly to the previous case that \( (r \mathcal{E}_1)_n' \) is a bicomplex. The identity which replaces (4.2) here is
\[
\sum_{j=0}^{r} (-1)^j c_{r+1-j,1}(e_j) = 0 \in \text{Dot} \left( \mathcal{F}^{(r)} \mathcal{E}^{(r+1)} W_{1n} \right).
\]

It can be proven by using the comultiplication of Schur functions implying that
\[
\Delta(c_{k,1}) = \sum_{i=0}^{k-1} c_i \otimes c_{k-i,1} + \sum_{i=1}^{k} c_i \otimes c_{k+1-i} + \sum_{i=2}^{k+1} c_{i-1,1} \otimes c_{k+1-i}.
\]

## 5 Chain Maps Between \( r \mathcal{E}_1 \) and \( (r \mathcal{E}_1)_n' \)

In this section, we will define the chain maps between \( r \mathcal{E}_1 \) and the intermediate complexes. The map \( f = \bigoplus_{k,l} f_{k,l} : r \mathcal{E}_1 \rightarrow (r \mathcal{E}_1)_n' \) is defined by
\[
f_{k,l} := \begin{cases} k+1 \end{cases} : C_{k,l} \mathcal{E} \rightarrow C'_{k,l},
\]
where \( \beta_{k,l} : A^l W_k \rightarrow \text{Dot}(\mathcal{F}^{(k)} \mathcal{E}^{(k)} W_{1n}) A^l W_k' \) will be specified below. Recall that \( W_k' = \text{Span}_\mathbb{Z}\{w_2, \ldots, w_{k+1}\} \).

Let us first define a linear map
\[
\beta_k : W_k \rightarrow \text{Dot} \left( \mathcal{F}^{(k)} \mathcal{E}^{(k)} \mathcal{E}_1 \right) W_k
\]
by
\[
\beta_k(w_i) = -w_i + \delta_{i,1} \sum_{j=2}^{k+1} c_{j-1} w_j + (-1)^{k+1-i} \left( e_{k+1-i} \right) w_{k+1},
\]
where \( (c_d)_{\mathcal{F}^{(k)} \mathcal{E}^{(k)} \mathcal{E}_1} = \sum_{i=0}^{d} \sum_{j=0}^{d-i} (-1)^i e_i \circ h_j \circ h_{d-i-j} \) and \( \delta_{i,j} \) is the Kronecker delta-function.

In the matrix form, this map can be represented as follows
\[
M(\beta_k) = \begin{pmatrix}
  c_1 & -1 & \ldots & 0 & 0 \\
  c_2 & 0 & \ldots & 0 & 0 \\
  \vdots & \vdots & \ddots & \vdots & \vdots \\
  c_{k-1} & 0 & \ldots & 0 & -1 \\
  c_k + (-1)^k (e_k) & (-1)^{k-1} (e_{k-1}) & \ldots & (e_2) & -(e_1) \\
\end{pmatrix}.
\]
where as before \((e_i)_2\) means that \(e_i\) sits on the second strand.

The map \(\beta_k\) extends to an algebra homomorphism

\[
\beta_k : \Lambda^* W_k \to \text{Dot} \left( \mathcal{F}(k) \mathcal{E}(k) \mathcal{E}1_n \right) \Lambda^* W_k'
\]

which in the matrix form can be written as \(\beta_k = \bigoplus_{l=0}^k \beta_{k,l}\). This defines the matrix \(\beta_{k,l}\) as the matrix of \((l,l)\)-minors of the matrix \(\beta_{k,1} = M(\beta_k)\) or, alternatively

\[
\beta_{k,l} \left( w_{i_1} \wedge w_{i_2} \wedge \cdots \wedge w_{i_l} \right) = \beta_k \left( w_{i_1} \right) \wedge \beta_k \left( w_{i_2} \right) \wedge \cdots \wedge \beta_k \left( w_{i_l} \right).
\]

We set \(\beta_{k,0} = 1\).

For example, with the same notation as before

\[
\beta_{3,2} = \begin{pmatrix}
c_2 & -c_1 & 1 \\
c_1(e_2)_2 + c_3 - (e_3)_2 & -c_1(e_1)_2 & (e_1)_2 \\
2(e_2)_2 & -c_2(e_1)_2 + c_3 - (e_3)_2 & (e_2)_2
\end{pmatrix},
\]

where each entry of this matrix is a determinant of the corresponding \(2 \times 2\) matrix of \(\beta_{3,1}\).

One can easily prove that

\[
\det(\beta_{k,1}) = \sum_{j=0}^k (-1)^j \begin{pmatrix}
c_{k-j} \\
e_j
\end{pmatrix} = \sum_{j=0}^k (-1)^j \begin{pmatrix}
e_j \\
h_{k-j}
\end{pmatrix}.
\]

The inverse matrix \(\bar{f} = \bigoplus_{k,l} \bar{f}_{k,l} : (rE1_n)' \to rE1_n\) is defined by

\[
\bar{f}_{k,l} = (-1)^k \begin{pmatrix}
\bar{\beta}_{k,l}
\end{pmatrix},
\]

where

\[
\bar{\beta}_{k,l} := \text{Adj}(\beta_{k,l}) = \det(\beta_{k,1}) \beta_{k,l}^{-1}
\]

is given by the adjugate matrix, or the transpose of the cofactor matrix for \(\beta_{k,l}\).

For example,

\[
\beta_{3,1} = \begin{pmatrix}
c_1 & -1 & 0 \\
c_2 & 0 & -1 \\
c_3 - (e_3)_2 & (e_1)_2 & (e_2)_2 - (e_1)_2
\end{pmatrix}
\]

and

\[
\bar{\beta}_{3,1} = \text{Adj}(\beta_{3,1}) = \begin{pmatrix}
(e_2)_2 & -c_1(e_1)_2 & 1 \\
c_2(e_1)_2 + c_3 - (e_3)_2 & -c_1(e_1)_2 \\
c_2(e_2)_2 & -c_1(e_2)_2 + c_3 - (e_3)_2 & c_2
\end{pmatrix}.
\]

**Proposition 5.1** The map \(f \bar{f} : (rE1_n)' \to (rE1_n)'\) is equal to identity.

**Proof** We have

\[
f_{k,l} \bar{f}_{k,l} = (-1)^k \begin{pmatrix}
det(\beta_{k,1}) \\
k \\
k+1
\end{pmatrix} = \sum_{j=0}^k (-1)^{k+j} \begin{pmatrix}
e_j \\
k \\
k+1
\end{pmatrix} \begin{pmatrix}
h_{k-j} \\
k \\
k+1
\end{pmatrix} = \begin{pmatrix}
1 \\
k+1
\end{pmatrix}.
\]
Proposition 5.2 The map \( f : rE_1 \rightarrow (rE_1)' \) is a chain map between bicomplexes.

Proof Let us first check the commutativity of the horizontal square

\[
\begin{array}{ccc}
C'_{k,l} & \xrightarrow{c' \wedge} & C'_{k,l+1} \\
\downarrow f_{k,l} & \quad & \downarrow f_{k,l+1} \\
C_{k,l} & \xrightarrow{(c)_{12} \wedge} & C_{k,l+1}
\end{array}
\]

We have to show that for any \( 1 \leq i_1 < i_2 < \cdots < i_l \leq k \)

\[
\sum_{i=2}^{k+1} c_{i-1,1} w_i \wedge \beta_k (w_{i_1}) \wedge \cdots \wedge \beta_k (w_{i_l})
= \sum_{i=1, i \neq i_j}^k (c_{i})_{12} \beta_k (w_{i_1}) \wedge \beta_k (w_{i_1}) \wedge \cdots \wedge \beta_k (w_{i_l}) \in \text{Dot} \left( \mathcal{F}(k) \mathcal{E}(k) \mathcal{E} \right) \Lambda^l W_k.
\]

Let us first assume \( i_1 > 1 \). After the substitution of maps, this identity can be rewritten as follows

\[
\begin{align*}
(-1)^{l+1} \sum_{i=2}^{k+1} c_{i-1,1} w_i \wedge w_{i_1} \wedge \cdots \wedge w_{i_l} \\
+(-1)^{l-1} \sum_{j=1}^{k+1} (-1)^{k+1-i_j} (e_{k+1-i_j})_2 c_{i-1,1} w_i \wedge \cdots \wedge \hat{w}_{i_j} \cdots \wedge w_{i_l} \wedge w_{k+1} \\
= (-1)^{l+1} \sum_{i=1}^{k} (c_{i})_{12} w_i \wedge w_{i_1} \wedge \cdots \wedge w_{i_l} + (-1)^{l} \sum_{i=2}^{k+1} (c_{i})_{12} c_{i-1,1} w_i \wedge w_{i_1} \wedge \cdots \wedge w_{i_l} \\
+(-1)^{l-1} \sum_{j=1}^{k+1} (-1)^{k+1-i_j} (c_{i})_{12} c_{i-1} (e_{k+1-i_j})_2 w_i \wedge w_{i_1} \wedge \cdots \wedge \hat{w}_{i_j} \cdots \wedge w_{i_l} \\
+(-1)^{l} \sum_{j=0}^{l} \sum_{i_0=1, i_0 \neq i_j}^{k} (-1)^{k+1-i_j} (c_{i_0})_{12} (e_{k+1-i_j})_2 w_{i_0} \wedge \cdots \wedge \hat{w}_{i_j} \cdots \wedge w_{i_l} \wedge w_{k+1}.
\end{align*}
\]

After accomplishing the \( j = 0 \) summand of the last term to zero by using (4.3) and applying twice

\[
c_{i-1,1} + (c_{i})_{12} - (c_{i})_{12} c_{i-1} = 0
\]  
(5.2)

it is not difficult to verify that it holds. The case \( i_1 = 1 \) reduces to the same identities and is left to the reader.

To see that \( f_{k+1,l}(d^V_{k,l} \mathcal{E}) = d^V_{k+1,l} f_{k,l} \), we need to verify that

\[
\begin{array}{ccc}
\beta_{k+1} & \xrightarrow{\alpha_{k}} & \beta_k \\
\downarrow & \quad & \downarrow \\
\alpha_k & \xrightarrow{\beta} & \alpha'_{k+1} \\
\end{array}
\]

\( : W_k \rightarrow \text{Dot} \left( \mathcal{F}(k) \mathcal{E}(k+1) \right) W'_{k+1} \)
which can be easily seen after the substitution of maps. Hence, also the induced maps $\Lambda^l W_k \to \text{Dot}(\mathcal{F}^{(k)} E^{(k+1)}) \Lambda^l W_{k+1}$ have to coincide.

**Theorem 5.3** The bicomplex $(r E_1)_n$ is a strong deformation retract of $r E_1$ in $\text{Kom}(\dot{U})$.

### 6 Proof of Theorem 5.3

This section is devoted to the proof of Theorem 5.3. After defining the homotopies, Propositions 6.1, 5.1 and 5.2 establish all properties of the strong deformation retract.

#### 6.1 Homotopies

The horizontal homotopy $h^H_{k,l} : C_{k,l} E \to C_{k,l-1} E$ is defined as follows

\[
\begin{array}{c}
\text{\begin{tikzpicture}[baseline={([yshift=-.5ex]current bounding box.center)}, scale=0.8]  
\draw (0,0) -- (0,2); 
\draw (1,0) -- (1,2); 
\draw (-1,0) -- (-1,2); 
\node at (0,2.5) {$k$}; 
\node at (0,-0.5) {$l$}; 
\node at (-1,0) {$q_{k,l}$}; 
\end{tikzpicture}}
\end{array}
\]

where $q_{k,l} : \Lambda^l W_k \to \text{Dot}(E^{(k-1)}) \Lambda^{l-1} W_k$

\[
q_{k,l}(w_{i_1} \wedge \cdots \wedge w_{i_l}) = \sum_{j=1}^{l} (-1)^{j-1} q_{k,1}(w_{i_j}) w_{i_1} \wedge \hat{w}_{i_j} \cdots \wedge w_{i_l}
\]

with $q_{k,1}(w_i) = (-1)^{i-1} e_{k-i}$. The vertical homotopy $h^V_{k,l} : C_{k,l} E \to C_{k-1,l} E$ is set to be zero.

Now Theorem 5.3 reduces to the following proposition.

**Proposition 6.1** We have

1. $f_{k,l-1} h^H_{k,l} = 0$;
2. $h^H_{k,l-1} h^H_{k,l} = 0$;
3. $h^H_{k+1,l_1}(d^V_{k,l_1} E) + (d^V_{k,l_1} E) h^H_{k,l} = 0$;
4. $h^H_{k,l+1}(d^H_{k,l} E) + (d^H_{k,l} E) h^H_{k,l} = 1 - \bar{f}_{k,l} f_{k,l}$.

**Proof** (1) The proof of the first identity requires to show that for any $1 \leq i, j \leq k$, we have

\[
\begin{array}{c}
\text{\begin{tikzpicture}[baseline={([yshift=-.5ex]current bounding box.center)}, scale=0.8]  
\draw (0,0) -- (0,2); 
\draw (1,0) -- (1,2); 
\draw (-1,0) -- (-1,2); 
\node at (0,2.5) {$k$}; 
\node at (0,-0.5) {$l$}; 
\node at (-1,0) {$e_{k-i}$}; 
\end{tikzpicture}}
\end{array} = 0
\]

and

\[
\begin{array}{c}
\text{\begin{tikzpicture}[baseline={([yshift=-.5ex]current bounding box.center)}, scale=0.8]  
\draw (0,0) -- (0,2); 
\draw (1,0) -- (1,2); 
\draw (-1,0) -- (-1,2); 
\node at (0,2.5) {$k$}; 
\node at (0,-0.5) {$l$}; 
\node at (-1,0) {$e_{k+1-j}$}; 
\end{tikzpicture}}
\end{array} - \begin{array}{c}
\text{\begin{tikzpicture}[baseline={([yshift=-.5ex]current bounding box.center)}, scale=0.8]  
\draw (0,0) -- (0,2); 
\draw (1,0) -- (1,2); 
\draw (-1,0) -- (-1,2); 
\node at (0,2.5) {$k$}; 
\node at (0,-0.5) {$l$}; 
\node at (-1,0) {$e_{k-j}$}; 
\end{tikzpicture}}
\end{array} = 0.
\]

To prove the first statement, we use the associativity of the trivalent vertices.
The second statement works similarly. We first move dots down, then cancel terms that coincide and finally use the same trick.

(2) Here we need to show that for all $0 \leq s, u \leq k - 1$

\[
\begin{align*}
&\quad = 0.
\end{align*}
\]

After sliding the upper $e_i$'s down and using the invariance under the third Reidemeister move, the left hand side of this identity become

\[
\begin{align*}
\quad = 0.
\end{align*}
\]

with $y := e_{s-1}e_u - e_{u-1}e_s$. Using associativity as in case (1), we can easily see that it is zero.

(3) The third equation follows from the following identity:

\[
\begin{align*}
&\quad = 0.
\end{align*}
\]

which holds for all $0 \leq s, u \leq k$ (here $e_{-1}$ are assumed to be zero). This identity is easy to prove by using the sliding rules from Appendix.

(4) Let us compute all terms of this equation. The “$dh$”-part contains the diagonal term of the form

\[
\sum_{s=1}^{k} (-1)^{s-1} e_{s-1} e_s = (-1)^{k-1} (c_k)_{13} = +(-1)^{k-1} (d_k)_{13}.
\]
The off-diagonal terms of \( dh \) and \( hd \) are

Finally, from the chain maps, we get

Due to (5.1), the first term in (6.2) cancels with the last term in (6.1) and the remaining terms cancel with the off-diagonal contributions from \( dh \) and \( hd \).

Further details are left to the reader.

7 Chain Maps Between \( E r_1 n \) and \( (rE 1 n)' \)

Let us denote by \( EC_{k,l} \) the “chain groups” of the complex \( E r_1 n \), obtained by composing \( E_1 n \) with \( r_1 n \). These groups are \( \mathcal{E}(k) E_1 n \otimes \Lambda^l W_k \langle -kn - k \rangle \) with the total degree shift \(-\frac{n^2}{2} - 3n - 4\). The differentials are those of \( r_1 n \) extended by identity on \( E_1 n \). The Euler characteristic of this complex is given by (4.4).

Define an algebra homomorphism

This extends to

defined by \( \gamma_k(w_{i_1} \wedge \ldots \wedge w_{i_l}) = \gamma_k(w_{i_1}) \wedge \ldots \wedge \gamma_k(w_{i_l}) \). We will also need another map

Let \( \gamma_{k,l} : \Lambda^l W_k \to \text{Dot}(\mathcal{E}(k-1) E_1 n) \otimes \Lambda^{l-1} W'_k \) be the derivation along the homomorphism \( \gamma_k \) induced by \( a_k \), i.e., \( \gamma_{k,0}(1) = 0 \) and for \( l \geq 0 \) we have

Let \( \gamma_{k,l} : \Lambda^l W_k \to \text{Dot}(\mathcal{E}(k-1) E_1 n) \otimes \Lambda^{l-1} W'_k \) be the derivation along the homomorphism \( \gamma_k \) induced by \( a_k \), i.e., \( \gamma_{k,0}(1) = 0 \) and for \( l \geq 0 \) we have

\[
\gamma_{k,l} (w_{i_1} \wedge \ldots \wedge w_{i_l}) = \sum_{j=1}^{l} (-1)^{j-1} a_k (w_{i_j}) \otimes \gamma_k (w_{i_1} \wedge \ldots \hat{w}_{i_j} \ldots \wedge w_{i_l}) .
\]
Then we define the map

\[ g_{k,l} := \gamma_{k,l} : \mathcal{E}C_{k,l} \to C_{k-1,l-1} \]

and set \( g = \oplus_{k,l} g_{k,l} : \mathcal{E}r1_n \to (r\mathcal{E}1_n)' \). The inverse map \( p = \oplus_{k,l} p_{k,l} : (r\mathcal{E}1_n)' \to \mathcal{E}r1_n \) is defined as follows

\[ p_{k,l} := \beta_{k,l} : C_{k-1,l-1}' \to \mathcal{E}C_{k,l}, \]

where \( b_{k,l}(w_{i_2} \wedge \ldots w_{i_l}) = (-1)^{k-1} \sum_{i=1}^{k} c_{i-1} \otimes w_i \wedge w_{i_2} \wedge \cdots \wedge w_{i_l} \).

**Theorem 7.1** The bicomplex \((r\mathcal{E}1_n)'\) is a strong deformation retract of the bicomplex \(\mathcal{E}r1_n\) in \(\text{Kom}((\mathcal{U}))\).

### 8 Proof of Theorem 7.1

We will split the proof of Theorem 7.1 into lemmas and prove them separately.

**Lemma 8.1** \( g : \mathcal{E}r1_n \to (r\mathcal{E}1_n)' \) is a chain map between bicomplexes, i.e.,

\[
\begin{align*}
d_{k-1,l-1}'^H g_{k,l} &= g_{k,l+1} (\mathcal{E}d_{k,l}^H) , \\
d_{k-1,l-1}'^V g_{k,l} &= f_{k+1,l} (\mathcal{E}d_{k,l}^V) .
\end{align*}
\]

**Proof** Let us check the commutativity of a general horizontal square

\[
\begin{array}{ccc}
C_{k-1,l-1}' & \xrightarrow{c'/\wedge} & C_{k-1,l}' \\
\uparrow g_{k,l} & & \uparrow g_{k,l+1} \\
\mathcal{E}C_{k,l} & \xrightarrow{(c)_{23}/\wedge} & \mathcal{E}C_{k,l+1}
\end{array}
\]

We assume \( k \geq 2 \), otherwise there is nothing to check. We start with

\[
\mathcal{E}T^{(k)} \mathcal{E}^{(k)} w_{i_1} \wedge \cdots \wedge w_{i_l} \in \mathcal{E}C_{k,l}
\]

and first apply the map \( g_{k,l} \) followed by \( d_{k-1,l-1}'^H \). Then we get

\[
\sum_{t=2}^{k} \sum_{j=1}^{l} (-1)^{j-1+k-i} c_{t-1,1} (e_{k-i}) 3 w_t \wedge \gamma_k (w_{i_1} \wedge \cdots \hat{w}_{i_j} \cdots \wedge w_{i_l}) . \tag{8.1}
\]
Applying first the differential and then the map, we get
\[
\sum_{j=0}^{l} \sum_{i_0=1}^{k} (-1)^{j+k-i_j} (c_{i_0})_{23} (e_{k-i_j})_{3} \gamma_k \left( w_{i_0} \wedge w_{i_1} \wedge \ldots \wedge \hat{w}_{i_j} \ldots \wedge w_{i_l} \right). \tag{8.2}
\]

We claim that these expressions are equal in Dot($\mathcal{F}^{(k-1)} \mathcal{E}^{(k)} \mathbf{1}_n \Lambda^l W')$. Indeed, assume $1 \neq i_1 < i_2 < \ldots < i_l$ and $t \neq i_s$ for all $1 \leq s \leq l$. Then collecting the coefficients in front of $w_t \wedge w_{i_1} \wedge \ldots \wedge \hat{w}_{i_j} \ldots \wedge w_{i_l}$ with $j > 1$ in both formulas we get $(-1)^{j+k-i_j} (e_{k-i_j})_{3}$ times
\[
c_t - 1 + (c_1)_{23} - (c_1)_{23} c_{t-1} = 0, \tag{8.3}
\]
where the last term comes from setting $i_0 = 1$ and picking the $t$th summand in $\gamma_k (w_1) = - \sum_{j=2}^{k} c_{j-1} w_j$.

Allowing $i_1 = 1$, but $i_j \neq 1$, leads to the same identity.

Let us consider the case $i_j = 1$. Collecting the coefficients of $w_t \wedge w_{i_2} \wedge \ldots \wedge w_{i_l}$ in (8.1), we get
\[
(-1)^{k-1} c_{t-1,1} (e_{k-1})_{3} + \sum_{j=2}^{l} (-1)^{k-i_j+1} (e_{k-i_j})_{3} (c_{t-1,1} c_{i_j-1} - c_{t-1} c_{i_j-1,1})
\]
and in (8.2)
\[
(-1)^{k} (c_{t})_{23} (e_{k-1})_{3} - \sum_{j=2}^{l} (-1)^{k-i_j+1} (e_{k-i_j})_{3} (c_1)_{23} c_{i_j-1} \]
\[- \sum_{p \neq 1, i_2, \ldots, i_l} (-1)^{k-p} (e_{k-p})_{3} (c_p)_{23} c_{t-1}.
\]

Using (8.3) few times, we can reduce the claim to (4.3).

Let us consider the following vertical square
\[
\mathcal{E} C_{k,l} \xrightarrow{g_{k,l}} C'_{k-1,l-1} \quad \mathcal{E} C_{k+1,l} \xrightarrow{g_{k+1,l}} C'_{k,l-1}
\]
\[
\mathcal{E} d_{k,l}^V \xrightarrow{d_{k,l}^V} \mathcal{E} d_{k-1,l}^V \quad \mathcal{E} d_{k-1,l}^V \xrightarrow{d_{k-1,l}^V} \mathcal{E} d_{k,l-1}^V
\]

Using similar considerations as before lead in all cases to the following true identity:

Lemma 8.2 We have $g p = 1 \in \text{End}(C'_{k-1,l-1})$. 

**Proof** Putting \( g \) on the top of \( p \) we get for any \( 1 < i_2 < \cdots < i_l \)

\[
gp(w_{i_2} \wedge \cdots \wedge w_{i_l}) = \sum_{j=1}^{l} \sum_{i_l = 1}^{k} (-1)^{j-i_l} e_{k-j} \gamma_{k,j-1} (w_{i_1} \wedge w_{i_2} \wedge \cdots \wedge \tilde{w}_{i_j} \cdot \cdot \cdot \wedge w_{i_l})
\]

which is equal to

\[
\sum_{i=1}^{k} (-1)^{i-1} (-1)^{i-j-1} e_{k-i} \gamma_{k,j-1} w_{i_2} \wedge \cdots \wedge w_{i_l}.
\]

\[
+ \sum_{j=2}^{l} \sum_{i=1}^{k} (-1)^{i-j-1} e_{k-j} \gamma_{k,j-1} w_{i_2} \wedge \cdots \wedge w_{i_l}.
\]

After cancellation, we get

\[
gp(w_{i_2} \wedge \cdots \wedge w_{i_l}) = \sum_{i=1}^{k} (-1)^{i-1} e_{k-i} \gamma_{k,j-1} w_{i_2} \wedge \cdots \wedge w_{i_l}.
\]

Using the Reidemeister move listed in Appendix, we can see that the only non-zero term without bubbles is the desired identity, and all the bubble terms cancel since

\[
\sum_{i=0}^{k-1} (-1)^{i} e_{k-1-i} = 0,
\]

where the last identity is equivalent to (4.2). Here we are again using centrality of \( c_i \)’s.
8.1 Horizontal Homotopy

Let $q_{k,1} : W_k \to \text{Dot}(\mathcal{E}^{(k-1)}1_n)$ be the map defined by $q_{k,1}(w_i) = (-1)^{i-1}e_{k-i}$. Then let $q_{k,l} : \Lambda^l W_k \to \text{Dot}(\mathcal{E}^{(k-1)}1_n) \otimes \Lambda^{l-1} W_k$ be the derivation induced by $q_{k,1}$, i.e.,

$$q_{k,l} (w_{i_1} \wedge \cdots \wedge w_{i_l}) = \sum_{j=1}^{l} (-1)^{j-1}q_{k,1}(w_{i_j}) w_{i_1} \wedge \cdots \hat{w}_{i_j} \cdots \wedge w_{i_l}.$$

We set

$$h^H_{k,l} := q_{k,l} : \mathcal{E}C_{k,l} \to \mathcal{E}C_{k,l-1}.$$

**Lemma 8.3** We have

$$g_{k,l-1} h^H_{k,l} = 0,$$

(8.5)

$$h^H_{k,l-1} \circ h^H_{k,l} = 0,$$

(8.6)

$$h^H_{k+1,l} (\mathcal{E}d^V_{k,l}) + (\mathcal{E}d^V_{k,l-1}) h^H_{k,l} = 0.$$  

(8.7)

**Proof** Equation (8.5) reduces to

$$e_j - e_i = 0$$

for $1 \leq i < j \leq k - 1$. Indeed, moving the line starting at the lowest left corner up through the 3-valent vertex (note that the bubble terms cancel) and then moving the $e_j$ and $e_i$ to the middle of the strand, we get that the left hand side is equal to

$$y := e_{j-1}e_i - e_{i-1}e_j.$$  

Now using the associativity and the invariance under the 3. Reidemeister move with all strands going in the same direction, we can see that both summands vanish.
Equation (8.6) reduces to the following identity

\[ e_j - e_i \quad \text{for} \quad 1 \leq i < j \leq k - 1, \] which can be proved similarly.

Finally, (8.7) follows from

\[ \text{(8.7)} \]

which holds for any \( 0 \leq i < j \leq k \).

### 8.2 Vertical Homotopy

We set

\[ h^V_{k,l} := \varepsilon_{C_{k,l}} : \varepsilon C_{k,l} \rightarrow \varepsilon C_{k-1,l} \]

where \( d_{k,l} : A^l W_k \rightarrow \text{Dot}(E^{(k)C_{1,n}}) \otimes A^l W_{k-1} \) is given by

\[
d_{k,0}(1) = (-1)^{k-1}(c_{k-1})_{12} = (-1)^{k-1} \left( \frac{c_{k-1}}{1} \right) \]

\[
d_{k,1}(w_i) = (-1)^k (c_{k-1})_{12} \cdot w_i + (-1)^{i-1} (e_{k-i})_3 \times (w_1 + c_1 w_2 + \cdots + c_{k-2} w_{k-1}) \quad \text{for} \quad i < k \]

\[
d_{k,1}(w_k) = (-1)^{k-1} (w_1 + c_1 w_2 + \cdots + c_{k-2} w_{k-1}) \quad \text{and} \]

\[
d_{k,l}(w_{i_1} \wedge \ldots \wedge w_{i_l}) = (-1)^{l-1} \left( (-1)^k (c_{k-1})_{12} \right)^{-l+1} \left( d_{k,1}(w_{i_1}) \wedge \ldots \wedge d_{k,1}(w_{i_l}) \right) \]

\[ + \sum_{j=1}^{l} (-1)^{i_j-1} \left( e_{k-i_j} \right)_3 \cdot w_{i_1} \wedge \ldots \wedge (X)_j \wedge \ldots \wedge w_{i_l}, \]

where \( X := \sum_{i=1}^{k-1} c_{i-1} w_i \) and \( (X)_j \) means that we replace \( w_{i_j} \) with \( X \). As before the lower indices indicate the strands on which the morphism is acting.
Let us illustrate this definition with few examples.

\[ d_{3,1} = \begin{pmatrix} -(c_2)_{12} + (e_2)_3 & -(e_1)_3 \\ (e_2)_{3c_1} & -(c_2)_{12} - (e_1)_{3c_1} \end{pmatrix} \]

\[ d_{3,1} \land d_{3,1} = \det \begin{pmatrix} -(c_2)_{12} + (e_2)_3 & -(e_1)_3 \\ (e_2)_{3c_1} & -(c_2)_{12} - (e_1)_{3c_1} \end{pmatrix} \]

Hence, we get

\[ d_{3,1} \land d_{3,1} = -(c_2)_{12}(-c_2, c_1, 1) \]

\[ d_{3,2} = (c_2, -c_1, 1). \]

Similarly, \( d_{k,k-1} = (c_{k-1}, -c_{k-2}, \ldots, (-1)^{k-2}c_1, (-1)^{k-1}1) \).

**Lemma 8.4** We have

\[ g_{k-1,l} h_{k,l}^V = 0, \]

\[ h_{k,l}^V p_{k,l} = 0, \]

\[ h_{k-1,l}^H h_{k,l}^V + h_{k-1,l}^V h_{k,l}^H = 0, \]

\[ h_{k,l+1}^H (E d_{k,l}^H) + h_{k+1,l}^V (E d_{k,l}^V) + (E d_{k+1,l}^H) h_{k,l}^V + (E d_{k,l+1}^V) h_{k,l}^H = 1 - p_{k,l} g_{k,l}. \]

**Proof** The proof of the last equality is based on the two identities given in Lemmas 5, 6 in Appendix. The rest is similar to the previous computations and hence left to the reader. \( \square \)

### 8.3 Proof of Lemma 1.4

Thus, we proved that the map

\[ \kappa_E : E rI_n \xrightarrow{g} (rE I_n)' \xrightarrow{f} rE I_n \]

has a homotopy inverse

\[ \tilde{\kappa}_E : E rI_n \leftarrow (rE I_n)' \leftarrow f rE I_n. \]

To construct \( \kappa_F \), we apply the symmetry \( \sigma \omega \) to \( \kappa_E \) assuming that Theorem 1.1 (Symmetry) holds. We get

\[ \tilde{\kappa}_F : rF I_{n+2} \xrightarrow{\sigma \omega (g)} (rE I_n)' \xrightarrow{\sigma \omega (f)} F rI_{n+2} \]

together with its homotopy inverse

\[ \kappa_F : rF I_{n+2} \xleftarrow{\sigma \omega (p)} (rE I_n)' \xleftarrow{\sigma \omega (f)} F rI_{n+2}. \]
8.4 Proof of Theorem 1.1 (Centrality)

We assume that Theorem 1.1 (Symmetry) holds.

Since any 1-morphism in \( \tilde{\mathcal{U}} \) is a direct sum of compositions of \( \mathcal{E}(t) \) and \( \mathcal{F}(t') \) with \( t, t' \in \mathbb{Z} \), it is enough to check the statement for the generators. Lemma 1.4 defines the maps \( \kappa_{\mathcal{E}} \) and \( \kappa_{\mathcal{F}} \) as well as their homotopy inverses. Applying symmetry, we can define \( \eta_{\mathcal{F}} = \psi(\tilde{\kappa}_{\mathcal{F}}) \) and \( \eta_{\mathcal{E}} = \psi(\kappa_{\mathcal{E}}) \). The details are left to the reader. \( \square \)

8.5 Comments on the Naturality of Maps \( \kappa_X \)

To prove Conjecture 1.2 (Naturality), we need to show that for any chain map \( f : X \to Y \), the squares below commute up to chain homotopy.

The commutativity of similar diagrams for \( \eta_X \) will follow then by applying symmetry functors. It is enough to check the commutativity for short chain complexes \( f : X \to Y \), where \( X, Y \) are \( \mathcal{E}_1, \mathcal{E}_2, \mathcal{F}\mathcal{E}_1 \) or \( 1_n \) and the differential is one of the generating 2-morphisms: dot, crossing, cup or cap. We leave this problem for future investigations.

9 Symmetry 2-functors

The 2-category \( \mathcal{U} \) has the symmetry group \( \mathcal{G} = (\mathbb{Z}/2\mathbb{Z})^3 \) generated by the involutive 2-functors \( \omega, \sigma, \psi \) described below.

9.1 2-functor \( \omega \)

Consider the operation on the diagrammatic calculus that rescales the crossing \( \square \) \( \mapsto \) \( \square \) for all \( n \in \mathbb{Z} \), inverts the orientation of each strand and sends \( n \mapsto -n \).

This gives a strict invertible 2-functor \( \omega : \mathcal{U} \to \mathcal{U} \) given by

\[
\omega : \mathcal{U} \to \mathcal{U} \\
1_n \mapsto -1_n \\
1_m \mathcal{E}^{\alpha_1} \mathcal{F}^{\beta_1} \mathcal{E}^{\alpha_2} \ldots \mathcal{E}^{\alpha_k} \mathcal{F}^{\beta_k} 1_n [s] \mapsto 1_{-m} \mathcal{F}^{\alpha_1} \mathcal{E}^{\beta_1} \mathcal{F}^{\alpha_2} \ldots \mathcal{F}^{\alpha_k} \mathcal{E}^{\beta_k} 1_{-n} [s].
\] (9.1)

This 2-functor extends to a 2-functor \( \omega : \text{Kom}(\mathcal{U}) \to \text{Kom}(\mathcal{U}) \)

\[
n \mapsto -n \\
(X^*, d) \mapsto \ldots \xrightarrow{\omega(d_{i-1})} \omega(X^i) \xrightarrow{\omega(d_i)} \omega(X^{i+1}) \xrightarrow{\omega(d_{i+1})} \ldots
\]

\( f_i : X^* \to Y^* \mapsto \omega(f_i) : \omega(X^*) \to \omega(Y^*) \).

Finally, this operation extends to the Karoubi envelope \( \hat{\mathcal{U}} \). The images of the idempotents \( e_a, e'_a \) under the 2-functor \( \omega \) are again idempotents.
The operation on diagrams that rescales the crossing \( \xrightarrow{\alpha} \xleftarrow{\beta} \) for all \( n \in \mathbb{Z} \), reflects a diagram across the vertical axis, and sends \( n \) to \(-n\) leaves invariant the relations on the 2-morphisms of \( \mathcal{U} \).

This operation is contravariant for composition of 1-morphisms, covariant for composition of 2-morphisms, and preserves the degree of a diagram. This symmetry gives an invertible 2-functor

\[
\sigma : \mathcal{U} \rightarrow \mathcal{U}^{\text{op}}
\]

\[
n \mapsto -n
\]

\[
1_m \mathcal{E}^{\alpha_1} \mathcal{F}^{\beta_1} \mathcal{E}^{\alpha_2} \cdots \mathcal{E}^{\alpha_k} \mathcal{F}^{\beta_k} 1_n \{s\} \mapsto 1_{-n} \mathcal{F}^{\beta_k} \mathcal{E}^{\alpha_k} \mathcal{F}^{\beta_{k-1}} \cdots \mathcal{F}^{\beta_1} \mathcal{E}^{\alpha_1} 1_{-m} \{-s\}
\]

that acts on 2-morphisms via the symmetry described above. This 2-functor extends to a 2-functor

\[
\sigma : \text{Kom}(\mathcal{U}) \rightarrow \text{Kom}(\mathcal{U})
\]

\[
n \mapsto -n
\]

\[
(X^\bullet, d) \mapsto \cdots \xrightarrow{\sigma(d_{i-1})} \sigma(X^i) \xrightarrow{\sigma(d_i)} \sigma(X^{i+1}) \xrightarrow{\sigma(d_{i+1})} \cdots
\]

\[
f_i : X^\bullet \rightarrow Y^\bullet \mapsto \sigma(f_i) : \sigma(X^\bullet) \rightarrow \sigma(Y^\bullet).
\]

Note that \( \sigma \) acts contravariantly on 1-morphisms in \( \text{Kom}(\mathcal{U}) \).

Furthermore, \( \sigma \) extends to a 2-functor \( \tilde{\mathcal{U}} \rightarrow \tilde{\mathcal{U}}^{\text{op}} \). A formula for \( \sigma(e_a) \) is given in [11, Eq. (5.59)].

### 9.3 2-functor \( \psi \)

This operation reflects across the horizontal axis and inverts orientation. This gives an invertible 2-functor defined by

\[
\psi : \mathcal{U} \rightarrow \mathcal{U}^{\text{co}}
\]

\[
n \mapsto n
\]

\[
1_m \mathcal{E}^{\alpha_1} \mathcal{F}^{\beta_1} \mathcal{E}^{\alpha_2} \cdots \mathcal{E}^{\alpha_k} \mathcal{F}^{\beta_k} 1_n \{s\} \mapsto 1_m \mathcal{E}^{\alpha_1} \mathcal{F}^{\beta_1} \mathcal{E}^{\alpha_2} \cdots \mathcal{E}^{\alpha_k} \mathcal{F}^{\beta_k} 1_n \{-s\}
\]

and on 2-morphisms \( \psi \) reflects the diagrams representing summands across the \( x \)-axis and inverts the orientation.

Since \( \psi \) is contravariant on 2-morphisms in \( \mathcal{U} \), this 2-functor extends to a 2-functor

\[
\psi : \text{Kom}(\mathcal{U}) \rightarrow \text{Kom}(\mathcal{U})
\]

\[
n \mapsto n
\]

\[
(X^\bullet, d) \mapsto \cdots \xrightarrow{\psi(d_{i-1})} \psi(X^{i+1}) \xrightarrow{\psi(d_i)} \psi(X^i) \xrightarrow{\psi(d_{i+1})} \psi(X^{i-1}) \xrightarrow{\psi(d_{i+2})} \cdots
\]

\[
f_i : X^\bullet \rightarrow Y^\bullet \mapsto \psi(f_i) : \psi(X^\bullet) \rightarrow \psi(Y^\bullet).
\]

Notice that \( \psi \) inverts the homological degree so that \( \psi \) acts on a complex \( (X^\bullet 1_n, \partial) \) in \( \text{Kom}(\mathcal{U}) \) by \( \psi(X^i) = (\psi X^\bullet)^{-i} \).

These 2-functors commute with each other ‘on-the-nose’

\[
\omega \sigma = \sigma \omega, \quad \sigma \psi = \psi \sigma, \quad \omega \psi = \psi \omega.
\]

As before, \( \psi \) extends to Karoubi envelopes providing a 2-functor \( \tilde{\mathcal{U}} \rightarrow \tilde{\mathcal{U}}^{\text{co}} \).

## 10 Symmetries of the Ribbon Bicomplex

In this section, we describe the behavior of the ribbon bicomplex under the symmetry 2-functors.

### 10.1 The Image Under $\omega$

The “chain groups” of the bicomplex $\omega(r_{1-n})$ are

$$\omega(C_{k,l}) := E^{(k)} F^{(k)}_{1} (n_{k-n}) \otimes A^{l} W_{k}, \quad W_{k} = \text{Span}_{\mathbb{Z}} \{ w_{1}, \ldots, w_{k} \}, \quad \text{deg}(w_{j}) = -2j$$

with the total shifts $\langle -\frac{n}{2} \rangle$ and $[n/2, n/2]$. The horizontal differential $\omega(d_{H}^{k,l}) : \omega(C_{k,l}) \to \omega(C_{k,l+1})$ sends $x \mapsto \omega(c) \land x$ where

$$\omega(c) := \sum_{j=1}^{k} \left( \sum_{i=0}^{j} (-1)^{i} e_{i}^{k} h_{j-i}^{k} \right) \otimes w_{j} \in \text{Dot} \left( E^{(k)} F^{(k)}_{1} n \right) \otimes W_{k}.$$

Similarly, the vertical differential is

$$\omega \left( d_{V}^{k,l} \right) := (-1)^{l} \alpha_{k,l}^{(k)} : \omega(C_{k,l}) \to \omega(C_{k+1,l}), \quad \text{where}$$

$$\alpha_{k,l}^{(k)} \left( w_{i_{1}} \land w_{i_{2}} \land \cdots \land w_{i_{l}} \right) = \mathbf{1} \otimes w_{i_{1}} \land \cdots \land w_{i_{l}}$$

$$- \sum_{j=1}^{l} (-1)^{k+1-j+i+j} \left( e_{k+1-i}^{k} h_{i_{j}}^{k} \right) \otimes \left( w_{i_{1}} \land \cdots \land w_{i_{j}} \land \cdots \land w_{i_{l}} \right) \land w_{k+1}.$$

Since all the relations in $\tilde{U}$ are invariant under symmetries, $\omega(r_{1-n})$ is a bicomplex.

### 10.2 The Image Under $\sigma$

The bicomplex $\sigma(r_{1-n})$ has the same “chain groups” as $\omega(r_{1-n})$ (i.e., $\sigma(C_{k,l}) = \omega(C_{k,l})$) with the differentials defined as follows: The horizontal differential $\sigma(d_{H}^{k,l}) : \sigma(C_{k,l}) \to \sigma(C_{k,l+1})$ sends $x \mapsto \sigma(c) \land x$ where

$$\sigma(c) := \sum_{j=1}^{k} \left( \sum_{i=0}^{j} (-1)^{i} e_{i}^{k} h_{j-i}^{k} \right) \otimes w_{j} \in \text{Dot} \left( E^{(k)} F^{(k)}_{1} n \right) \otimes W_{k}.$$

Similarly, the vertical differential is

$$\sigma \left( d_{V}^{k,l} \right) := (-1)^{l} \alpha_{k,l}^{(k)} : \sigma(C_{k,l}) \to \sigma(C_{k+1,l}),$$
where $\alpha_{k,l} \in \text{Dot}(E^{(k)} \mathbf{1}_n) \otimes \Lambda^l W_{k+1}$ is defined by (4.1).

### 10.3 The Image Under $\psi$

The 2-functor $\psi$ is contravariant on the 2-morphisms in $\hat{\mathcal{U}}$; hence, the bicomplex $\psi(r \mathbf{1}_n)$ looks as follows

$$
\begin{array}{cccc}
C^L_{00} & \rightarrow & C^L_{01} & \rightarrow \ C^L_{11} \\
\uparrow & & \uparrow & \uparrow \\
\rightarrow C^L_{10} & \rightarrow & C^L_{11} & \rightarrow \ C^L_{21} \\
\uparrow & & \uparrow & \uparrow \\
\rightarrow C^L_{20} & \rightarrow & C^L_{21} & \rightarrow \ C^L_{22} \\
\uparrow & & \uparrow & \uparrow \\
\rightarrow C^L_{30} & \rightarrow & C^L_{31} & \rightarrow \ C^L_{32} \\
\uparrow & & \uparrow & \uparrow \\
\rightarrow \ldots & \rightarrow & \ldots & \rightarrow \ldots
\end{array}
$$

where the “chain groups” are

$$C^L_{k,l} := \psi(C_{k,l}) = \mathcal{E}^{(k)} \mathcal{E}^{(k)} \mathbf{1}_n (kn + k) \otimes \Lambda^l \tilde{W}_k$$

with the total shifts $(\frac{n^2}{2} + n)$ and $[-n/2, -n/2]$. The horizontal differential $\psi(d^H_{k,l}) : C^L_{k,l+1} \rightarrow C^L_{k,l}$ sends

$$\tilde{w}_{i_1} \wedge \cdots \wedge \tilde{w}_{i_{l+1}} \mapsto \sum_{j=1}^{l} (-1)^{j-1} c_j \otimes \tilde{w}_{i_1} \wedge \cdots \wedge \tilde{w}_{i_j} \wedge \tilde{w}_{i_{j+1}},$$

where as before $(c_d)_{\mathcal{E}^{(k)} \mathcal{E}^{(k)} \mathbf{1}_n} = \sum_{j=0}^{d} (-1)^j e_j \otimes h_{d-j}$. The vertical differential is

$$\psi(d_{k,l}^V) := (-1)^l \begin{array}{ccc}
k \\
\uparrow & \uparrow & \uparrow \\
\alpha_{k,l} & C^L_{k+1,l} & \rightarrow C^L_{k,l}
\end{array} : C^L_{k+1,l} \rightarrow C^L_{k,l}$$

with $\alpha_{k,l}$ defined as before by (4.1).

It is easy to see that $\sigma \omega \psi(r \mathbf{1}_n) = r^{-1} \mathbf{1}_n$.

### 11 Isomorphic Bicomplex

This section provides a construction of the bicomplex $\tilde{r} \mathbf{1}_n$, which is isomorphic to the ribbon bicomplex and invariant under $\sigma \omega$.
11.1 The Isomorphism $H$

Let $W = \text{Span}_{\mathbb{Z}}\{w_1, w_2, \ldots\}$ and $W_A = A \otimes W$. Then there exists an isomorphism $H : W_A \to W_A$ with

$$H(w_m) := \sum_{j \geq m} h_{j-m} w_j.$$ 

Its inverse is defined by replacing $h_i$ with its antipode $(-1)^i e_i$; hence, we have

$$H^{-1}(w_m) = \sum_{j \geq m} (-1)^{j-m} e_{j-m} w_j.$$

We can use this map to define a non-trivial transformation $H_{k, l} : C_{k, l} \to C_{k, l}$ of the “chain groups” $C_{k, l} = \mathcal{F}(k) \mathcal{E}(k) 1_n \otimes \Lambda^l W_k$ of the ribbon bicomplex as follows. For $l = 1$, we set

$$H_{k, 1} := \begin{pmatrix}
1 & 0 & 0 & 0 & \ldots & 0 \\
(h_1)_2 & 1 & 0 & 0 & \ldots & 0 \\
(h_2)_2 & (h_1)_2 & 1 & 0 & \ldots & 0 \\
(h_3)_2 & (h_2)_2 & (h_1)_2 & 1 & \ldots & 0 \\
\ldots & \ldots & \ldots & \ldots & \ldots & 0 \\
(h_{k-1})_2 & (h_{k-2})_2 & (h_{k-3})_2 & (h_{k-4})_2 & \ldots & 1
\end{pmatrix} = (h_{i-j})_{1 \leq i, j \leq k}, \quad (11.1)$$

where the matrix is written in the basis $w_1, w_2, \ldots, w_k$ and all symmetric polynomials are sitting on the second strand.

This map obviously extends to $\Lambda^l W_k$ by setting

$$H_{k, l} \left( w_{i_1} \wedge w_{i_2} \wedge \cdots \wedge w_{i_l} \right) := \left( \Lambda^l H_{k, 1} \right) \left( w_{i_1} \wedge w_{i_2} \wedge \cdots \wedge w_{i_l} \right) = H_{k, 1} \left( w_{i_1} \right) \wedge H_{k, 1} \left( w_{i_2} \right) \wedge \cdots \wedge H_{k, 1} \left( w_{i_l} \right).$$

Inserting (11.1), we get

$$H_{k, l} \left( w_{i_1} \wedge w_{i_2} \wedge \cdots \wedge w_{i_l} \right) := \sum_{1 \leq j_1 < j_2 < \cdots < j_l \leq k} \sum_{\sigma \in S_l} (-1)^{\sigma} \left( h_{j_1-i_{\sigma(1)}} \right)_2 \left( h_{j_2-i_{\sigma(2)}} \right)_2 \cdots \left( h_{j_l-i_{\sigma(l)}} \right)_2 w_{i_1} \wedge w_{i_2} \wedge \cdots \wedge w_{i_l}.$$

Hence, for $1 \leq i_1 < i_2 < \cdots < i_l \leq k$ and $1 \leq j_1 < j_2 < \cdots < j_l \leq k$

$$(H_{k, l})_{i_1, i_2, \ldots, i_l}^{j_1, j_2, \ldots, j_l} = \sum_{\sigma \in S_l} (-1)^{\sigma} \left( h_{j_1-i_{\sigma(1)}} \right)_2 \left( h_{j_2-i_{\sigma(2)}} \right)_2 \cdots \left( h_{j_l-i_{\sigma(l)}} \right)_2.$$

The inverse map is defined in a similar way by using

$$H^{-1}_{k, 1} := \begin{pmatrix}
1 & 0 & 0 & 0 & \ldots & 0 \\
-(e_1)_2 & 1 & 0 & 0 & \ldots & 0 \\
-(e_2)_2 & -(e_1)_2 & 1 & 0 & \ldots & 0 \\
-(e_3)_2 & (e_2)_2 & -(e_1)_2 & 1 & \ldots & 0 \\
\ldots & \ldots & \ldots & \ldots & \ldots & 0 \\
(-1)^{k-1}(e_{k-1})_2 & (-1)^{k-2}(e_{k-2})_2 & (-1)^{k-3}(e_{k-3})_2 & (-1)^{k-4}(e_{k-4})_2 & \ldots & 1
\end{pmatrix} \quad \text{or}$$

$$(H^{-1}_{k, 1})_{i, j} = (e_{i-j})_2 \left( (e_{i-j})_2 \right)_{1 \leq i, j \leq k}.$$
For $1 \leq i_1 < i_2 \cdots < i_l \leq k$ and $1 \leq j_1 < j_2 \cdots < j_l \leq k$, we have
\[
(H_{k,l}^{-1})_{i_1,i_2,\ldots,i_l}^{j_1,j_2,\ldots,j_l} = (-1)^{\sum_i i_j + j_i} \sum_{\sigma \in S_l} (-1)^\sigma \left( e_{j_1-i_{\sigma(i)}} \right)_{2} \left( e_{j_2-i_{\sigma(2)}} \right)_{2} \cdots \left( e_{j_l-i_{\sigma(l)}} \right)_{2}.
\]

### 11.2 The Bicomplex $\bar{r}1_n$

Let us denote by $\bar{r}1_n$ the image of $r1_n$ under applying the isomorphism $H_{k,l}$ to each “chain group” $C_{k,l}$. The horizontal and vertical differentials of $\bar{r}1_n$ are given by
\[
\bar{d}^H_{k,l} := H_{k,l+1}^{-1} d^H_{k,l} H_{k,l}, \quad \bar{d}^V_{k,l} := H_{k+1,l}^{-1} d^V_{k,l} H_{k,l}.
\]

Let us compute them.

We start with $\bar{d}^H_{k,0} = H_{k,1}^{-1} d^H_{k,0} = H_{k,1}^{-1} \sum_{i=1}^{k} c_i w_i$. Thus, the $i$th entry of $\bar{d}^H_{k,0}$ is
\[
\sum_{j=0}^{i-1} (-1)^{i-j} \left( e_{i-j} \right)_{2} c_j = \left( (c_i)_1 - (-1)^i \left( e_{i} \right)_{2} \right) = (-1)^i \left( ((e_i)_1 - (e_i)_2) =: y_i \in \text{Dot} \left( \mathcal{F}^{(k)} \mathcal{E}^{(k)} 1_n \right) \right).
\]

In the general case,
\[
\bar{d}^H_{k,l} (w_{i_1} \wedge \cdots \wedge w_{i_l}) = \left( A^{l+1} H_{k,1} \right)^{-1} \left( c \wedge \left( A^l H_{k,1} \right) (w_{i_1} \wedge \cdots \wedge w_{i_l}) \right)
\]
\[
= \left( H_{k,1}^{-1} c \right) \wedge w_{i_1} \wedge \cdots \wedge w_{i_l}
\]
\[
= \sum_{i=1}^{k} y_i w_i \wedge w_{i_1} \wedge \cdots \wedge w_{i_l},
\]

where we used the centrality of $c$ and the previous computation. Observe that $\bar{d}^H_{k,l} = \sigma \omega (\bar{d}^H_{k,l})$.

To compute the vertical differential, we will need the following notation:

\[
\begin{align*}
\mathcal{I}^p := \{ & k+1 & k+1 \\
& p & k \\
& k & k
\end{align*}
\]

Then it is easy to verify that $(e_j)_2 T_0 = t_0 (e_j)_2 + t_1 (e_{j-1})_2$ or more generally
\[
\left( e_{m_1} \cdots e_{m_l} \right)_2 T_0 = \sum_{a=0}^{l} t_a \sum_{T \subset \{1,2,\ldots,l\}} \left( e_{m_1-e_1(T)} \cdots e_{m_l-e_l(T)} \right)_2 \cdot
\]

where $(xy)_2 = (x)_2 (y)_2$ and
\[
\varepsilon_p (T) = \begin{cases} 1, & p \in T \\ 0, & p \notin T \end{cases}
\]

For instance
\[
\left( e_{m_1} e_{m_2} e_{m_3} \right)_2 T_0
\]
\[
= t_0 \left( e_{m_1} e_{m_2} e_{m_3} \right)_2 + t_1 \left( \left( e_{m_1-e_1} e_{m_2} e_{m_3} \right)_2 + \left( e_{m_1} e_{m_2-e_1} e_{m_3} \right)_2 + \left( e_{m_1} e_{m_2} e_{m_3-e_1} \right)_2 \right)
\]
\[
+ t_2 \left( \left( e_{m_1-e_1} e_{m_2-e_1} e_{m_3} \right)_2 + \left( e_{m_1-e_1} e_{m_2} e_{m_3-e_1} \right)_2 + \left( e_{m_1} e_{m_2-e_1} e_{m_3-e_1} \right)_2 \right)
\]
\[
+ t_3 \left( e_{m_1-e_1} e_{m_2-e_1} e_{m_3-e_1} \right)_2.
\]
For simplicity, we put $t_0 = t$. With this notation, let us first compute the matrix for the vertical differential in the case when $l = 1$. Inserting (11.1), (11.2) into (11.3), we get

$$ (dV_{k,1})_{i,j} = \begin{cases} -\sum_{p=0}^{i-j} (-1)^p (e_p) \cdot t (h_{i-j-p})_2 & \text{if } i - j \geq 0 \\ 0 & \text{otherwise}, \end{cases} $$

where $\delta_{i,j}$ is the Kronecker delta-function. For example, for $k = 3$, we have

$$ d_{k,1} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ -(e_1)_2 & 1 & 0 & 0 \\ -(e_2)_3 & -(e_1)_2 & 1 & 0 \\ -(e_1)_3 & -(e_2)_2 & -(e_1)_2 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ (e_2)_2 & (h_1)_2 & 1 \end{pmatrix}. $$

In general, for $1 \leq i_1 < i_2 \cdots < i_l \leq k$ and $1 \leq j_1 < j_2 \cdots < j_l \leq k$ using the computation for $l = 1$ case, we get

$$ (dV_{k,l})_{i_1,\ldots,i_l} = (-1)^l \sum_{1 \leq p_1 < \cdots < p_l \leq k} \sum_{1 \leq s_1 < \cdots < s_l \leq k+1} (H_{k+l+1,1})_{j_1,\ldots,j_l}^s \cdot (\alpha_{k,l})_{p_1,\ldots,p_l} \cdot (H_{k,l})_{i_1,\ldots,i_l}^{p_1,\ldots,p_l}. $$

By (11.4), we obtain

$$ (H_{k+l+1,1})_{j_1,\ldots,j_l}^s = \sum_{a=0}^l (-1)^a t_a \cdot \sum_{\sigma \in S_l} (-1)^\sigma \cdot \sum_{T \subset \{1,2,\ldots,l\}} \prod_{|T|=a} e_{j_T - k_\sigma(s) - \epsilon_s(T)} \cdot \prod_{|T|=a} (H_{k+l+1,1})_{j_1,\ldots,j_l}^{p_1,\ldots,p_l}, $$

where $j_T^s := j_T - \epsilon_s(T)$. Hence

$$ (dV_{k,l})_{i_1,\ldots,i_l} = (-1)^l \sum_{a=0}^l (-1)^a t_a \cdot \sum_{T \subset \{1,2,\ldots,l\}} \prod_{|T|=a} \delta_{j_T^s,i_1} \cdot \prod_{|T|=a} (H_{k+l+1,1})_{j_1,\ldots,j_l}^{p_1,\ldots,p_l}. $$

Observe that $\sigma \omega(t_a) = t_a$ and hence $d_{k,l} = \sigma \omega(d_{k,l}^V)$.  

\[ \text{For simplicity, we put } t_0 = t. \text{ With this notation, let us first compute the matrix for the vertical differential in the case when } l = 1. \text{ Inserting (11.1), (11.2) into (11.3), we get}
\]

\[
(dV_{k,1})_{i,j} = \begin{cases} -\sum_{p=0}^{i-j} (-1)^p (e_p) \cdot t (h_{i-j-p})_2 & \text{if } i - j \geq 0 \\
0 & \text{otherwise}, \end{cases}
\]

where $\delta_{i,j}$ is the Kronecker delta-function. For example, for $k = 3$, we have

\[
d_{k,1} = \begin{pmatrix} 1 & 0 & 0 & 0 \\
-(e_1)_2 & 1 & 0 & 0 \\
-(e_2)_3 & -(e_1)_2 & 1 & 0 \\
-(e_1)_3 & -(e_2)_2 & -(e_1)_2 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
(h_1)_2 & (h_2)_2 & (h_1)_2 & 1 \end{pmatrix}.
\]

In general, for $1 \leq i_1 < i_2 \cdots < i_l \leq k$ and $1 \leq j_1 < j_2 \cdots < j_l \leq k$ using the computation for $l = 1$ case, we get

\[
(dV_{k,l})_{i_1,\ldots,i_l} = (-1)^l \sum_{1 \leq p_1 < \cdots < p_l \leq k} \sum_{1 \leq s_1 < \cdots < s_l \leq k+1} (H_{k+l+1,1})_{j_1,\ldots,j_l}^s \cdot (\alpha_{k,l})_{p_1,\ldots,p_l} \cdot (H_{k,l})_{i_1,\ldots,i_l}^{p_1,\ldots,p_l}.
\]

By (11.4), we obtain

\[
(H_{k+l+1,1})_{j_1,\ldots,j_l}^s = \sum_{a=0}^l (-1)^a t_a \cdot \sum_{\sigma \in S_l} (-1)^\sigma \cdot \sum_{T \subset \{1,2,\ldots,l\}} \prod_{|T|=a} e_{j_T - k_\sigma(s) - \epsilon_s(T)} \cdot \prod_{|T|=a} (H_{k+l+1,1})_{j_1,\ldots,j_l}^{p_1,\ldots,p_l},
\]

where $j_T^s := j_T - \epsilon_s(T)$. Hence

\[
(dV_{k,l})_{i_1,\ldots,i_l} = (-1)^l \sum_{a=0}^l (-1)^a t_a \cdot \sum_{T \subset \{1,2,\ldots,l\}} \prod_{|T|=a} \delta_{j_T^s,i_1} \cdot \prod_{|T|=a} (H_{k+l+1,1})_{j_1,\ldots,j_l}^{p_1,\ldots,p_l}.
\]

Observe that $\sigma \omega(t_a) = t_a$ and hence $d_{k,l} = \sigma \omega(d_{k,l}^V)$.  

\[ \text{For simplicity, we put } t_0 = t. \text{ With this notation, let us first compute the matrix for the vertical differential in the case when } l = 1. \text{ Inserting (11.1), (11.2) into (11.3), we get}
\]
12 Proof of the Invertibility of the Ribbon Complex

12.1 The 2-functor $\Gamma_N$

Let us recall the definition of the 2-functor $\Gamma_N$ from [12, Section 7]. On objects the 2-functor $\Gamma_N$ sends $n$ to the ring $H_{k,N}$ whenever $n$ and $k$ are compatible

$$\Gamma_N : \mathcal{U} \rightarrow \text{Flag}_N$$

$$n \mapsto \begin{cases} H_{k,N} & \text{with } n = 2k - N \text{ and } 0 \leq k \leq N, \\ 0 & \text{otherwise.} \end{cases}$$ (12.1)

1-Morphisms of $\mathcal{U}$ get mapped by $\Gamma_N$ to graded bimodules

$$\Gamma_N : \mathcal{U} \rightarrow \text{Flag}_N$$ (12.2)

$$i_n(s) \mapsto \begin{cases} H_{k,N}(s) & \text{with } n = 2k - N \text{ and } 0 \leq k \leq N, \\ 0 & \text{otherwise.} \end{cases}$$

$$e^1_n(s) \mapsto \begin{cases} H_{k+1,N}(s + 1 - N + k) & \text{with } n = 2k - N \text{ and } 0 \leq k < N, \\ 0 & \text{otherwise.} \end{cases}$$

$$f^1_n(s) \mapsto \begin{cases} H_{k-1,N}(s + 1 - k) & \text{with } n = 2k - N \text{ and } 0 < k \leq N, \\ 0 & \text{otherwise}, \end{cases}$$

where the cohomology of the Grassmannian is given by

$$H_{k,N} := \mathbb{Z}[x_1,n, x_2,n, \ldots, x_k,n; y_{1,n}, \ldots, y_{N-k,n}] / I_{k,N}$$

with $I_{k,N}$ the homogeneous ideal generated by elements equating powers of $t$ in the equation

$$(1 + x_1,n \cdot t + \cdots + x_k,n \cdot t^k) \ (1 + y_{1,n} \cdot t + \cdots + y_{N-k,n} \cdot t^{N-k}) = 1.$$ 

The cohomology of the $a$th iterated 1-step flag variety $H_{\xi,N}$ with $\xi = (k, k + 1, k + 2, \ldots, k + a)$ is given by

$$H_{\xi,N} := \mathbb{Z}[x_1,n, x_2,n, \ldots, x_k,n; \xi_1, \ldots, \xi_a; y_{1,n+2a}, \ldots, y_{N-k-a,n+2a}] / I_{\xi,N}$$

with $I_{\xi,N}$ the homogeneous ideal generated by elements equating powers of $t$ in the equation

$$(1 + x_1,n \cdot t + \cdots + x_k,n \cdot t^k) \ (1 + \xi_1 t) (1 + \xi_2 t) \ldots (1 + \xi_a t)$$

$$(1 + y_{1,n+2a} \cdot t + \cdots + y_{N-k-a,n+2a} \cdot t^{N-k-a}) = 1.$$ 

We will also use the cohomology of $a$-step flag variety corresponding to the sequence $\xi = (k, k + a)$ given by

$$H_{k,k+a,N} := \mathbb{Z}[x_1,n, x_2,n, \ldots, x_k,n; \epsilon_1, \ldots, \epsilon_a; y_{1,n+2a}, \ldots, y_{N-k-a,n+2a}] / I_{k,k+a,N}$$

with $I_{k,k+a,N}$ the homogeneous ideal generated by elements equating powers of $t$ in the equation

$$(1 + x_1,n \cdot t + \cdots + x_k,n \cdot t^k) \ (1 + \epsilon_1 t + \cdots + \epsilon_a t^a)$$

$$(1 + y_{1,n+2a} \cdot t + \cdots + y_{N-k-a,n+2a} \cdot t^{N-k-a}) = 1.$$
It will be convenient in what follows to introduce a simplified notation in \( \text{Flag}_N \). Corresponding to a fixed value of \( N \), we set \( n = 2k - N \) and write
\[
\mathbb{1}^N_n := \Gamma_N(1_n)
\]
\[
\mathbb{E}^N_n = \mathbb{1}^N_{n+2}\mathbb{E} = \mathbb{1}^N_{n+2}\mathbb{E}^N_n := \Gamma_N(\mathbb{E}1_n)
\]
\[
\mathbb{F}^N_n = \mathbb{1}^N_{n-2}\mathbb{F} = \mathbb{1}^N_{n-2}\mathbb{F}^N_n := \Gamma_N(\mathbb{F}1_n)
\]
as a shorthand for the various bimodules. Juxtaposition of these symbols represents the tensor product of the corresponding bimodules. For example
\[
\mathbb{F}\mathbb{E}\mathbb{E}^N_n = H_{k+1,k+2,N} \otimes H_{k+2,N} \otimes H_{k+1,N} H_{k+1,k,N}.
\]
Associated with a signed sequence \( \epsilon \) is the \((H_{k+|\epsilon|}, H_k)\)-bimodule
\[
\mathbb{E}_\epsilon \mathbb{1}^N_n := \mathbb{E}_{\epsilon_1} \mathbb{E}_{\epsilon_2} \ldots \mathbb{E}_{\epsilon_m} \mathbb{1}^N_n,
\]
where \( \mathbb{E}_+ := \mathbb{E} \) and \( \mathbb{E}_- := \mathbb{F} \). The 2-functor \( \Gamma_N \) maps a composite \( \mathbb{E}_\epsilon 1_n \) of 1-morphisms in \( \mathcal{U} \) to the tensor product \( \mathbb{E}_\epsilon \mathbb{1}^N_n \) in \( \text{Flag}_N \). Note that because tensor product of bimodules is only associative up to coherent isomorphism, our notation is ambiguous unless we choose a parenthesization of the bimodules in question. We employ the convention that all parenthesis are on the far left. Hence, \( \Gamma_N \) preserves composition of 1-morphisms only up to coherent 2-isomorphism.

It is sometimes convenient to use the following isomorphisms from [3].
\[
\Gamma_N(\mathbb{E}^a 1_n) \cong H_{k+a,k+a-1,...,k;N} \langle r_a \rangle, \quad r_a = \sum_{i=1}^a i - N + k \tag{12.3}
\]
\[
\Gamma_N(\mathbb{F}^a 1_n) \cong H_{k,k+1,...,k+a;N} \langle r'_a \rangle, \quad r'_a = \sum_{i=1}^a i - k. \tag{12.4}
\]
We also define bimodules
\[
\mathbb{E}^{(a)} \mathbb{1}^N_n := H_{k+a,k;N} \left( r_a - \frac{a(a-1)}{2} \right).
\]
\[
\mathbb{F}^{(b)} \mathbb{1}^N_n := H_{k+a,k;N} \left( r_a + \frac{a(a-1)}{2} \right). \tag{12.5}
\]

Let us denote by \( r^N \mathbb{1}_n \) the image under \( \Gamma_N \) of the ribbon complex.

### 12.2 Proof of Theorem 1.5

We first prove that tensoring on the left (or on the right) with \( r^N \mathbb{1}_n \) acts as a left (resp. right) multiplication with the identity on any left (resp. right) \( H_{k;N} \)-module up to degree shift.

We will consider the left action only, the right action can be proved similarly. Note that it is enough to compute the left action of \( r^N \mathbb{1}_n \) on \( H_{k;N} \). Let us first ignore the homological shift for simplicity.

Set \( n = N \). Then \( r^N \mathbb{1}_N = \mathbb{1}^N_N \langle -N^2/2 - N \rangle \) in \( \text{Kom(Flag}_N \rangle \), simply because \( \mathbb{E} \mathbb{1}^N_N = 0 \), and the result holds.

Assume \( n = N - 2k \), then
\[
\mathbb{F}^k \mathbb{1}^N_n \cong \mathbb{F}^k r^N \mathbb{1}_N = \mathbb{F}^k \mathbb{1}^N_n \langle -N^2/2 - N \rangle.
\]
where the first homotopy equivalence holds due to centrality of \( r \mathbf{1}_n^N \). Now observe that:

\[
F^k \mathbf{1}_N^N \simeq \bigoplus_{[k]} F^{(k)} \mathbf{1}_N^N
\]

in \( \text{Flag}_N \). Hence, \( r \mathbf{1}_n^N \) acts as a left multiplication with \( \mathbf{1}_n^N (-N^2/2 - N) \) on \( F^{(k)} \mathbf{1}_n^N \) in \( \text{Com}(\text{Flag}_N) \). But \( F^{(k)} \mathbf{1}_n^N \) is isomorphic to \( H_{k;N} = \mathbf{1}_n^N \) as a left module over itself. Hence we have the first statement.

Similarly, tensoring with \( r^{-1} \mathbf{1}_n^N \) on the left and on the right is homotopic to the identity functor shifted by \( (N^2/2 + N) \), which is inverse to \( r \mathbf{1}_n^N \). Since homological shifts for \( r \mathbf{1}_n \) and \( r^{-1} \mathbf{1}_n \) are inverse to each other, we have the result.

12.3 The Inverse Limit of Schur Quotients

The Schur quotient \( \hat{U}_N \) of \( \hat{U} \) is defined by setting \( \mathbf{1}_{N+2}^N = 0 \) (see [14] for a more general definition). Applying \( \text{sl}(2) \) relations, an easy induction argument shows that \( \mathbf{1}_n = 0 \) in \( \hat{U}_N \) for all \( n < -N \) and \( n > N \). Moreover, this quotient is not empty, since the functor \( \Gamma_N : \hat{U} \to \text{Flag}_N \) factorizes through \( \hat{U}_N \) by its very definition.

For any \( N' > N \), there is a natural projection

\[
\Psi_{N',N} : \hat{U}_{N'} \to \hat{U}_N
\]

defined by setting \( \mathbf{1}_{N+2}^N = 0 \). Taking all together, these maps define an inverse system of 2-categories whose inverse limit is \( \hat{U} \) (compare [3]).

Now let us consider \( \text{Com}^b(\hat{U}_N) \). The induced functor \( \text{Com}^b(\hat{U}) \to \text{Com}^b(\text{Flag}_N) \) factorizes again through \( \text{Com}^b(\hat{U}_N) \). Using the natural projections

\[
\Psi_{N',N} : \text{Com}^b(\hat{U}_{N'}) \to \text{Com}^b(\hat{U}_N)
\]

for all \( N' > N \), we can construct

\[
\lim \leftarrow \text{Com}^b(\hat{U}_N)
\]

Observe that \( r^\pm 1 \mathbf{1}_n \) belongs to \( \lim \leftarrow \text{Com}(\hat{U}) \), since its projections to \( \text{Com}^b(\hat{U}_N) \) are well-defined for all \( N \) and compatible with each other.

12.4 Proof of Theorem 1.1 (Invertibility)

By the universal property of the inverse 2-limit, we get a 2-functor

\[
\hat{\Gamma} : \lim \leftarrow \text{Com}(\hat{U}) \to \text{Com}^b(\text{Flag}_N),
\]

unique up to 2-isomorphism in \( \text{iBicat} \), making the diagram

\[
\begin{array}{ccc}
\lim \leftarrow \text{Com}^b(\hat{U}_N) & \xrightarrow{\hat{\Gamma}} & \lim \leftarrow \text{Com}^b(\text{Flag}_N) \\
\pi^{-1} \downarrow & & \pi^{-1} \\
\text{Com}^b(\text{Flag}_{N+2}) & \xrightarrow{\pi^{-1}} & \text{Com}^b(\text{Flag}_N)
\end{array}
\]

commute up to 2-isomorphism in \( \text{iBicat} \). Note that \( \text{iBicat} \) is a bicategory with objects bicategories, morphisms (pseudo) 2-functors and 2-morphisms given by icons.
Now the arguments in [3] (e.g., proof of Theorem 3.2) imply that this 2-functor \( \tilde{\Gamma} : \text{Col}(\mathcal{U}) \to \lim \text{Com}^b(\text{Flag}) \) is an equivalence of 2-categories in \( \text{iBicat} \). Since \( r r^{-1}1_n = \tilde{\Gamma}^{-1}(\lim \mathbb{1}^N_n) \) by Theorem 1.5, we get the desired result.

Acknowledgments The first author would like to thank Aaron Lauda for helpful discussions and Krzysztof Putyra for sharing his LaTeX package for drawing diagrams.

Funding Open access funding provided by University of Zurich.

Appendix

Let us collect the identities we need in the proofs.

Sliding Rules

Generalizing the NilHecke algebra relations to the thick lines, we get

\[
\begin{align*}
  k & \quad k \\
  h_n & \quad h_i \\
  &= \quad \sum_{i+j=k=n-1} h_j \\
\end{align*}
\]

(A.1)

\[
\begin{align*}
  l & \quad k \\
  e_n & \quad e_k \\
  &= \quad e_n \\
\end{align*}
\]

(A.2)

In particular, if \( l = 1 \), we have

\[
\begin{align*}
  k & \quad k \\
  h_n & \quad h_i \\
  &= \quad \sum_{i+j=n-1} h_j \\
\end{align*}
\]

(A.3)

\[
\begin{align*}
  l & \quad k \\
  e_n & \quad e_k \\
  &= \quad e_n \\
\end{align*}
\]

(A.4)

In what follows an \( x \) labeled bullet on a thick line will mean \( h_x \) inserted.

Reidemeister Moves

From [11, Corollary 5.8] (for \( b = k, a = 1 \)) and the bubble slide rule (4.11), we get

\[
\begin{align*}
  k & \quad k \\
  = (-1)^k & \quad (+1)^{k-1} \sum_{x+u+x+t=k+n-2} \circ x \\
\end{align*}
\]

(A.5)
Analogously, [11, Theorem 5.6 and (4.12)] imply

\[
= (-1)^k \sum_{x+u+s+t=k+n-2} (-1)^k + \sum_{s+t+x+u+v=n-k+1} (-1)^{k-1} \sum_{s+t+x+u+v=k-n-3} (-1)^k
\]

Similar, to the proof of [12, Proposition 5.8], we can show that for all colors \( n \in \mathbb{Z} \) of the right most region, the following equation holds:

\[
(A.6)
\]

**Further Identities**

**Lemma A.1**

\[
\begin{array}{c}
\sum_{i=1}^{k} (-1)^{k-i} c_{i-1} + (-1)^k + \sum_{i=1}^{k} (-1)^{i-1} c_{k-i} = e_{k-i}
\end{array}
\]

**Proof** We first simplify the last summand of this identity by using the fact that \( c_i \) is central and

\[
\sum_{i=1}^{k} (-1)^{k-i} c_{i-1} + (-1)^k + \sum_{i=1}^{k} (-1)^{i-1} c_{k-i} = e_{k-i}
\]

Then we apply (A.6) to the second summand on the right hand side. Furthermore, we use

\[
\begin{array}{c}
\sum_{i=1}^{k} (-1)^{k-i} c_{i-1} + (-1)^k + \sum_{i=1}^{k} (-1)^{i-1} c_{k-i} = e_{k-i}
\end{array}
\]

to simplify the resulting terms. The last equality follows from (A.3) to (A.4). It is easy to check that all terms with bubbles sum to zero.
Lemma A.2 For $1 \leq i, j \leq k$, we have

\[
\begin{array}{c}
\begin{array}{c}
\hspace{1cm} c_{i-1} - c_{j-1} \\
\hspace{1cm} e_{j-1}
\end{array}
\end{array}
\end{align*}

Proof We first apply (A.6) to the first two summands on the right hand side, then all diagrams without smoothings will look as shown below.

The strategy of the proof will be to move all dots into the position shown by the dashed line. Doing so for the last two summands, we get

\[
c_{i-1} (e_1)_3 (e_{j-1})_4 - c_{j-1} (e_1)_1 (e_{j-1})_4 \in \text{Dot} \left( \mathcal{E} \mathcal{F}^{(k)} \mathcal{E}^{(k-1)} \right)
\]

minus the second term on the left hand side of the identity (obtained after sliding the dot though the down pointed $k$-line), and in addition various terms with bubbles. Let us first compare the terms without smoothings. The second term on the right hand side will contribute:

\[
-c_{i} (e_{j-1})_4 \in \text{Dot} \left( \mathcal{E} \mathcal{F}^{(k)} \mathcal{E}^{(k-1)} \right).
\]

Finally, in the first term on the right hand side, we replace $(c_{i})_{23}$ with $c_{i} - c_{i-1} (e_1)_1$ and move the dot down. The contribution of this term to the part without smoothings will be

\[
c_{i} (e_{j-1})_4 - c_{j-1} (e_1)_3 (e_{j-1})_4 \in \text{Dot} \left( \mathcal{E} \mathcal{F}^{(k)} \mathcal{E}^{(k-1)} \right)
\]

and in addition from moving the dot, we get the first term on the left hand side. Collecting all non-smoothed terms together we get zero. It remains to show that all bubble terms vanish. This easy check is left to the reader. \[\square\]
