The instability of rotating Kerr black holes due to massive scalar perturbations is investigated. It is well known that a bosonic field impinging on a Kerr black hole can be amplified as it scatters off the hole. This superradiant scattering occurs for frequencies in the range $\omega < m\Omega$, where $\Omega$ is the angular frequency of the black hole and $m$ is the azimuthal harmonic index of the mode. If the incident field has a non-zero rest mass, $\mu$, then the mass term effectively works as a mirror, reflecting the scattered wave back towards the black hole. The wave may bounce back and forth between the black hole and some turning point amplifying itself each time. This may lead to a dynamical instability of the system, a phenomena known as a “black-hole bomb”. In this work we provide a bound on the instability regime of rotating Kerr spacetimes. In particular, we show that Kerr black holes are stable to massive perturbations in the regime $\mu \geq \sqrt{2}m\Omega$.

If a black hole is perturbed in some small way, will the perturbation die away over time? Or will it grow exponentially until it can no longer be considered a perturbation and hence demonstrate the instability of the black hole? The fundamental role played by black holes in many areas of modern physics (astrophysics, high-energy physics, condensed matter physics) makes it highly important to study the nature of their stability.

Regge and Wheeler [1] have provided evidence for the stability of the spherically symmetric Schwarzschild black hole. In particular, they have shown that if a Schwarzschild black hole is perturbed, then the perturbation will oscillate and damp out over time [1,2]. This implies that perturbation fields which propagate in the black-hole exterior would either be radiated away to infinity or swallowed by the black hole.

It is well known that realistic stellar objects generally rotate about their axis and are therefore not spherical. Thus, an astrophysically realistic model of wave dynamics in black-hole spacetimes must involve a non-spherical background geometry with angular momentum. The stability question of rotating Kerr black holes is more complicated than the spherically-symmetric Schwarzschild case. Press and Teukolsky [3,4] have shown that rotating black holes are stable under free gravitational perturbations (see also [5] and references therein). However, the superradiance effect may change this conclusion. Superradiant scattering is a well-known phenomena in quantum systems [6,7] as well as in classical ones [8,9]. Considering a wave of the form $e^{im\phi}e^{-i\omega t}$ (where $m$ and $\omega$ are real) incident upon a rotating object whose angular velocity is $\Omega$, one finds that if the frequency $\omega$ of the incident wave satisfies the relation

$$\omega < m\Omega,$$

then the scattered wave is amplified.

A bosonic field impinging upon a rotating Kerr black hole can be amplified if the superradiance condition (1) is satisfied, where in this case

$$\Omega = \frac{a}{r_+^2 + a^2}$$

is the angular velocity of the black-hole horizon. Here $r_+$ and $a$ are the horizon radius and the angular momentum per unit mass of the black hole, respectively. The energy radiated away to infinity may actually exceed the energy present in the initial perturbation. Feeding back the amplified scattered wave, one can gradually extract the rotational energy of the black hole. Press and Teukolsky suggested to use this mechanism to build a black-hole bomb [10]: If one surrounds the black hole by a reflecting mirror, the wave will bounce back and forth between the black hole and the mirror amplifying itself each time. Thus, the total energy extracted from the black hole will gradually grow.

Remarkably, nature sometimes provides its own mirror [9]: If one considers a massive scalar field with mass $\mathcal{M}$ scattered off a rotating black hole, then for $\omega < \mu \equiv \mathcal{M}G/\hbar c$ the mass term effectively works as a mirror [11,17]. The physical idea is to consider a wave packet of the massive field in a bound orbit around the black hole [12,13]. The gravitational force binds the field and keeps it from escaping to infinity. At the event horizon some of the field goes down the black hole, and if the frequency of the wave is in the superradiance regime (1) then the field is amplified. In this way the field is amplified at the horizon while being bound away from infinity. This may lead to a dynamical instability of the system [11,17].
Former studies [11–17] of the dynamics of massive scalar fields in rotating Kerr spacetimes have shown that the superradiant instability (the black hole bomb mechanism) depends on two parameters:

- The angular frequency $\Omega$ of the black hole.
- The dimensionless product of the black hole mass $M$ and the field mass $\mu$. The product $M\mu$ is actually the ratio of the black hole size to the Compton wavelength associated with the rest mass of the field. (We shall henceforth use natural units in which $G = c = \hbar = 1$. In these units $\mu$ has the dimensions of $1/\text{length}$.)

In particular, it has been proved [18] that the solutions of the massive scalar equation in the Kerr spacetime are stable in the regime

$$\mu \geq m\Omega \sqrt{1 + \frac{2M}{r_+} + \frac{a^2}{r_+^2}}.$$  \hfill (3)

Recently, an improved bound for $\mu$ above which the solutions of the massive scalar equation are stable was given in [19]:

$$\mu \geq m\Omega \sqrt{1 + \frac{2M}{r_+}}.$$  \hfill (4)

Below we shall provide a stronger bound for the stability regime of rotating Kerr black holes: we shall show that the solutions of the massive Klein-Gordon equation in the Kerr spacetime are stable in the regime

$$\mu \geq m\Omega \cdot \sqrt{2}$$  \hfill (5)

for all $a$ values.

The physical system we consider consists of a massive scalar field coupled to a rotating Kerr black hole. The dynamics of a scalar field $\Psi$ of mass $\mu$ in the Kerr spacetime [20] is governed by the Klein-Gordon equation

$$(\nabla^a \nabla_a - \mu^2)\Psi = 0.$$  \hfill (6)

One may decompose the field as

$$\Psi_{lm}(t, r, \theta, \phi) = e^{im\phi} S_{lm}(\theta; a\omega) R_{lm}(r; a\omega)e^{-i\omega t},$$  \hfill (7)

where $(t, r, \theta, \phi)$ are the Boyer-Lindquist coordinates [20], $\omega$ is the (conserved) frequency of the mode, $l$ is the spheroidal harmonic index, and $m$ is the azimuthal harmonic index with $-l \leq m \leq l$. (We shall henceforth omit the indices $l$ and $m$ for brevity.) With the decomposition (7), $R$ and $S$ obey radial and angular equations both of confluent Heun type coupled by a separation constant $K(a\omega)$ [21–25]. The sign of $\omega_I$ determines whether the solution is decaying ($\omega_I < 0$) or growing ($\omega_I > 0$) in time. Remembering that any instability must set in via a real-frequency mode [26] we shall consider here modes with $|\omega_I| \ll \omega_R$. (It should be emphasized that Ref. [26] considered only the massless case.)

The angular functions $S(\theta; a\omega)$ are the spheroidal harmonics which are solutions of the angular equation [22, 27, 30]

$$\frac{1}{\sin \theta \partial \theta} \left(\sin \theta \frac{\partial S}{\partial \theta}\right) + \left[K - a^2(\omega^2 - \mu^2) + a^2(\omega^2 - \mu^2) \cos^2 \theta - \frac{m^2}{\sin^2 \theta}\right] S = 0.$$  \hfill (8)

The angular functions are required to be regular at the poles $\theta = 0$ and $\theta = \pi$. These boundary conditions pick out a discrete set of eigenvalues $\{K_{lm}\}$ labeled by the integers $l$ and $-l \leq m \leq l$.

The radial Klein-Gordon equation is given by [28, 31]

$$\Delta \frac{d}{dr} \left(\Delta \frac{dR}{dr}\right) + UR = 0,$$  \hfill (9)

where $\Delta \equiv r^2 - 2Mr + a^2$, and

$$U \equiv [(r^2 + a^2)\omega - ma]^2 + \Delta[2ma\omega - K - \mu^2(r^2 + a^2)].$$  \hfill (10)

The zeroes of $\Delta$, $r_{\pm} = M \pm (M^2 - a^2)^{1/2}$, are the black hole (event and inner) horizons.
We are interested in solutions of the radial equation (9) with the physical boundary conditions of purely ingoing waves at the black-hole horizon (as measured by a comoving observer) and a decaying (bounded) solution at spatial infinity \[12, 15\]. That is,

\[ R \sim e^{-i(\omega - m\Omega)y} \quad \text{as} \quad r \to r_+ \quad (y \to -\infty), \]  
(11)

and

\[ R \sim \frac{1}{r} e^{-\sqrt{\mu^2 - \omega^2}y} \quad \text{as} \quad r \to \infty \quad (y \to \infty), \]  
(12)

where the “tortoise” radial coordinate \( y \) is defined by \( dy = [(r^2 + a^2)/\Delta]dr \) [32]. For frequencies in the superradiant regime (1), the boundary condition (11) describes an outgoing flux of energy and angular momentum from the rotating black hole \[12, 15\]. Note also that a bound state (a state decaying exponentially at spatial infinity) is characterized by

\[ \omega^2 < \mu^2. \]  
(13)

The boundary conditions (11)-(13) single out a discrete set of resonances \( \{\omega_n\} \) which correspond to the bound states of the massive field \[12, 15\]. (We note that, in addition to the bound states of the massive field, the field also has an infinite set of discrete quasinormal resonances \[33–36\] which are characterized by outgoing waves at spatial infinity.)

It is convenient to define a new radial function \( \psi \) by

\[ \psi \equiv \Delta^{1/2}R, \]  
(14)

in terms of which the radial equation (9) can be written in the form of a Schrödinger-like wave equation

\[ \frac{d^2\psi}{dr^2} + (\omega^2 - V)\psi = 0, \]  
(15)

where

\[ \omega^2 - V = \frac{U + M^2 - a^2}{\Delta^2}. \]  
(16)

Below we shall need the asymptotic form of the effective potential which is given by

\[ V(r) = \mu^2 - \frac{4M\omega^2 - 2M\mu^2}{r} + O\left(\frac{1}{r^2}\right). \]  
(17)

As discussed above, the instability of the Kerr spacetime to massive scalar perturbations is a consequence of massive modes which are trapped inside the effective potential well outside the black hole. These modes are superradiantly amplified in the ergo-region near the black-hole horizon. Two ingredients are therefore required in order to trigger the instability:

- The existence of a trapping potential well outside the black hole.
- The existence of an ergo-region, in which superradiant amplification of the waves takes place.

For the effective potential to have a trapping well, its asymptotic derivative must be positive \( V' \to 0^+ \) as \( r \to \infty \). Taking cognizance of Eqs. (13) and (17), one finds that bound states may exist for modes in the regime

\[ \frac{\mu^2}{2} < \omega^2 < \mu^2. \]  
(18)

In Table I we test the validity of the inequality \( \frac{\mu^2}{2} < \omega^2 \) for the bound states of the massive scalar field. For this conformation we use numerical results for the bound state frequencies of massive scalar fields in Kerr spacetimes, see also \[15\]. From Table I one indeed learns that all bound states (for all \( a \) values) conform to the inequality (18).

In addition to the requirement (18) for the existence of a trapping well, the superradiance condition for amplification of the scattered waves is given by \[\text{see Eq. (1)}\]

\[ \omega < m\Omega. \]  
(19)
TABLE I: Massive scalar bound states of rotating Kerr black holes. The data shown is for the mode $l = m = 1$ and for various values of the rotation parameter $a$, see also [15]. We display the ratio $\min_{M \mu} \left\{ \frac{2 \omega^2}{\mu^2} \right\}$ for the numerically computed frequencies. (We also display the dimensionless product $M \mu^*$, where the ratio $\frac{2 \omega^2}{\mu^2}$ attains its minimum.) One finds $\frac{2 \omega^2}{\mu^2} > 1$ for all $a$ values, in agreement with the inequality (18).

| $a/M$ | $M \mu^*$ | $\min_{M \mu} \left\{ \frac{2 \omega^2}{\mu^2} \right\}$ |
|-------|-----------|---------------------------------------------|
| 0.0   | 0.943     | 1.677                                       |
| 0.3   | 1.005     | 1.618                                       |
| 0.5   | 1.032     | 1.580                                       |
| 0.7   | 1.021     | 1.522                                       |
| 0.9   | 0.933     | 1.473                                       |
| 0.99  | 0.869     | 1.466                                       |
| 0.999 | 0.867     | 1.465                                       |

One therefore realizes that the two conditions for superradiant instability [see Eqs. (18) and (19)] can be satisfied in the restricted regime $\mu/\sqrt{2} < \omega < m\Omega$. In other words, the dynamics of the massive scalar field is expected to be stable in the complementary regime $\mu \geq \sqrt{2} \cdot m\Omega$. In summary, we have studied the instability of rotating Kerr black holes to massive scalar perturbations. In particular, we have shown that the two conditions which are necessary for the existence of the superradiant instability [namely: (1) the existence of a trapping well, and (2) superradiant amplification of the trapped modes] can only be satisfied in the restricted regime $\mu < \sqrt{2} \cdot m\Omega$. Thus, the dynamics of the massive scalar field in the Kerr spacetime is expected to be stable in the complementary regime $\mu \geq \sqrt{2} \cdot m\Omega$. This provides an improved bound on the stability regime of the massive Klein-Gordon equation in rotating Kerr spacetimes.

It should be noticed that the solutions of Eq. (9) with the boundary conditions (11)-(12) do not assume values in the natural Hilbert space that is associated to the reduced Klein-Gordon equation of Refs. [18, 19] due to their asymptotic behavior at \( r_+ \).

It is worth noting that for unbound states (those with \( \omega > \mu \)), one can deduce a stronger bound on the stability region: 
\[
\mu \geq m\Omega.
\]
This bound follows from the couple of inequalities: (1) \( \omega > \mu \) which characterizes the unbound states, and (2) \( \omega < m\Omega \) for the existence of superradiant amplification. Thus, unbound states may be unstable only in the restricted regime \( \mu < m\Omega \).
