INTRODUCTION

The renal and cardiovascular systems have a unique and intricate inter-relationship, with disease or dysfunction in one organ frequently leading to injury in the other. This complex interaction has led to the use of the term “cardio-renal syndrome” (Ronco et al., 2009; Hajhosseiny et al., 2013). Overall, for subjects with chronic kidney disease (CKD) stage 3, it is more likely that a patient will develop cardiovascular disease (CVD) than progress to dialysis-requiring renal failure (CKD stage 5D; Bleyer et al., 2006; Hajhosseiny et al., 2013). Sudden cardiac death (SCD) is particularly prevalent amongst patients with CKD, with estimates ranging from 25 to 60% (Herzog, 2003; Pun et al., 2009).

In dialysis patients, the incidence of SCD is very high; eclipsing other causes of cardiac death, and rises with both the duration of time that the patient has been on a dialysis program, as well as the severity and frequency of dialysis-associated electrolyte imbalances (Karnik et al., 2001; Bleyer et al., 2006).

Until recently, electrocardiographic early repolarization (ER) was considered a benign finding on a patient’s electrocardiogram (ECG). However, a number of recent studies have suggested that ER may represent an independent marker of sudden arrhythmic cardiac arrest in otherwise healthy individuals (Haissaguerre et al., 2008; Ghosh et al., 2010; Sinner et al., 2010; Tikkanen et al., 2012). Despite this, it is currently unknown whether or not there is a similar increased prevalence of ER in CKD patients in whom SCD is common. The aim of the current study was therefore to determine the prevalence of ER, possible contributory factors,
and whether or not ER is related to all-cause mortality and progression to dialysis in patients with CKD.

**METHODS**

**PATIENTS**

We retrospectively studied adults with stage 3–5 CKD referred to the Nephrology department at Guy’s and St. Thomas’ Hospital between March 2007 and December 2011. Our study population consisted of newly diagnosed patients with CKD, or patients with follow-up appointments. In addition, we also studied 39 adults without CKD to control for the effects of renal failure on ER. These controls were healthy renal transplant donors (RTD) with no documentation of structural heart disease or a history of syncope. Full demographic data pertaining to cardiovascular risk factors, prior cardiac history, current medications, and concurrent co-morbidities were recorded along with recent laboratory results (renal profile, serum calcium, and hs C-reactive protein levels). Cardiovascular risk factors were determined by pre-set defined criteria. Hypertension was defined as a systolic blood pressure of >140 mmHg, a diastolic blood pressure of >90 mmHg, or antihypertensive drug use. Smoking was defined as a current smoker or past heavy smoker (>20 package-years). Diabetes mellitus was defined as a previously established diagnosis, insulin, or oral hypoglycemic therapy, fasting glucose of >126 mg/dL, or non-fasting glucose of >200 mg/dL. Family history of coronary artery disease was defined as myocardial infarction, coronary revascularization, or SCD in a first-degree relative <65 years old. A 12-lead ECG was performed on all patients and the primary inclusion criteria were based on CKD severity and the availability of a recent adequate ECG recording in their clinical file. Patients with permanent pacemakers were excluded from the study. All patients were followed up for a minimum time period of 12-months from the data of the first ECG. Written informed consent was obtained from the 19 haemodialysis patients for obtaining an ECG before and after dialysis and the study was granted institutional ethics committee approval in accordance with the Helsinki Declaration (1964, amended in 1975 and in 1984).

**ECG ACQUISITION AND ANALYSIS**

All patients underwent a 12-lead ECG. These were fully interrogated by two electrophysiologists blinded to the clinical data for relevant electrical intervals (PR, QRS, and QTc durations), and for bundle branch block, the cardiac axis, left ventricular hypertrophy (LVH), and ER. The presence or absence of LVH was assessed according to the Sokolow–Lyon criteria and the QT interval was corrected for heart rate according to Bazett’s formula. Early repolarization was defined as an elevation of the QRS-ST junction (J point) in at least two leads. The amplitude of J-point elevation had to be at least 1 mm (0.1 mV) above the baseline level either as QRS slurring (a smooth transition from the QRS segment to the ST segment—**Figure 1A**) or notching (a positive J deflection inscribed on the S wave—**Figure 1B**) in the inferior leads (II, III, and aVF), lateral leads (I, aVL, and V4–V6), or both. The anterior precordial leads (V1–V3) were excluded from the analysis to avoid the inclusion of patients with right ventricular dysplasia or Brugada syndrome. In order to account for the effects of dialysis on ER, we obtained an ECG recording from 19 patients on hemodialysis immediately prior to the start of their dialysis session, and followed this up with the acquisition of another ECG immediately after their dialysis session had finished.

**FOLLOW UP**

In order to investigate the prognostic and predictive value of ER, all patients (CKD and controls) were followed up for 12 months from the start of the study. The primary endpoint was all-cause mortality (all cause) and the secondary endpoint, the new commencement of dialysis.

**STATISTICAL ANALYSIS**

All continuous variables included in the analysis are presented as mean ± SD. Variables with non-normal distributions are presented as median with range. Univariate analyses were performed on continuous variables using the two-sample *t*-test for normally distributed variables and the Mann–Whitney *U* test for non-normally distributed data. Spearman’s correlation coefficient was used to assess the relationship between continuous variables. Multivariable logistic regression was used to determine the predictors of ER using age, presence of COPD, mineralocorticoid receptor antagonist use, heart rate, PR interval, QRS interval, and dialysis as covariates. Statistical significance for all analyses was set at the 5% level. All data were collected and analyzed using SPSS for MAC (Version 19, IBM, Somers, NY, USA).

---

**FIGURE 1 | The identification of ER from the 12-lead electrocardiogram. (A) Shows a typical example of a slurred patterned ER (arrows) while (B) shows the appearance of a notched ER (arrows).**
RESULTS

The baseline demographics of the population are given in Table 1. There were 202 patients with CKD stage 3–5 who were approached for inclusion into the study. Of these, 5 patients were excluded due to the presence of a permanent cardiac pacemaker. In the remaining cohort of 197 patients, the ethnic origin was Caucasian in 121 (61%), Afro-Caribbean in 60 (31%), and South Asian in 16 (8%). There was a prior cardiac history present in 62 (32%) patients [8 (4%) congestive cardiac failure, 47 (24%) coronary artery disease, 14 (16%) myocardial infarction, 8 (4%) valvular heart disease and 14 (7%) atrial fibrillation].

PREVALENCE OF EARLY REPOLARIZATION IN PATIENTS WITH AND WITHOUT CKD

Table 2 gives the comparison of baseline demographics between the 197 patients with CKD and the 39 healthy renal donors who represented the control group. The healthy renal donors were of a younger age and were predominantly Caucasian in ethnic origin. Although there was a tendency to an increased prevalence of ER in the CKD population (19.8%) compared with the renal donors (7.7%), this did not reach statistical significance ($P = 0.07$). There was no difference observed in the magnitude or distribution of J-point elevation. Prevalence of ER in pre-dialysis patients with CKD stage 4 and 5 was higher than in the RTD (26.4 vs. 7.7%, $p = 0.02$). Early repolarization frequency increased with CKD stage (stage 3: 7.7%, stage 4: 29.7%, and pre-dialysis stage 5: 24.6%), but decreased in dialysis patients (13%).

PREDICTORS OF EARLY REPOLARIZATION

In the CKD group of patients, age, gender, ethnicity, prior cardiac history, cardiovascular risk factors, eGFR, and CKD stage were unrelated to the presence of ER (Table 3). Similarly, there was no relationship to the use of cardiac medications or serum electrolytes and biochemistry. There were however a number of ECG predictors of ER. Patients with ER had lower heart rates (HR with ER $71 \pm 15$ BPM vs. $77 \pm 17$ without ER, $p = 0.03$), shorter QRS durations (QRS duration with ER $84 \pm 11$ vs. $94 \pm 21$ without ER, $p < 0.01$), and shorter QTc durations (QTc duration with ER $412 \pm 22$ vs. $427 \pm 34$ without ER, $p < 0.001$). On multivariate analysis (Table 4) with ER as the dependent variable and age, presence of COPD, mineralocorticoid receptor antagonist use, heart rate, PR interval, QRS interval, and dialysis as covariates, only the QRS duration remained a significant independent predictor of ER (OR 0.97, 95% CI, 0.94–0.99, $p = 0.01$).

EARLY REPOLARIZATION AS A PREDICTOR OF ALL-CAUSE MORTALITY AND PROGRESSION TO DIALYSIS

At 1-year follow-up, there were 24 deaths. There was no difference in mortality between those who had ER (13% (5 of 39 patients) to those who did not (12%) (19 of 158 patients), $p = 1.0$ (Figure 2). From the 119 patients who were not already on dialysis at the study commencement, 56 (47%) patients progressed to either peritoneal or hemodialysis. Of the 29 patients with ER who were not yet on dialysis, 15 (52%) progressed to renal replacement therapy, compared with 41 (46%) of the 90 patients without ER ($p = 0.67$).

DISCUSSION

The main finding of the current study is that there is an increased prevalence of ER in CKD patients (20%) when compared to healthy controls (8%). We also show that the presence of ER is
associated to a shorter QRS duration in patients with CKD but that this did not translate to an increased incidence of all-cause mortality or progression to dialysis at 1-year follow-up.

A number of prior studies have suggested a relationship between the presence of ER and SCD. Haisaguerre et al. (2008) conducted a multicentre study of 206 patients resuscitated after an episode of idiopathic ventricular fibrillation. The authors found that there was an increased prevalence of ER (31%) when compared to 412 age, gender, and race matched controls (5%), and that there was an increased prevalence of ER (31%) when compared to 412 age, gender, and race matched controls (5%). In a study of 1945 individuals aged between 35 and 74 years of age (Sinner et al., 2010), participants with ER compared to individuals without ER.

Although the exact mechanism of ER-induced arrhythmogenicity is still unclear, it has been hypothesized that this may be related to either an increased susceptibility or vulnerability to cardiac arrest in critical ischemic conditions such as acute coronary syndromes (Tikkanen et al., 2012), or to subtle changes in the cardiac action potential (Benito et al., 2010). Early repolarization in its simplest form occurs in Phase 1 of the cardiac action potential and is caused by the cardiac transient outward potassium current ($I_{to}$). If a situation arises where there is a reduced density of the

| Parathormone (PTH) | 191 (97–396) | 221 (100–368) | 183 (97–404) | 0.92 |
| CRP               | 6 (5–20)  | 6 (5–12)       | 6 (5–24)  | 0.30 |
| Hemoglobin (g/dL)  | 10.8 ± 1.9 | 10.8 ± 1.9    | 10.7 ± 1.9 | 0.82 |

**ELECTROCARDIOGRAM**

| Heart Rate (bpm) | 76 ± 17 | 71 ± 15 | 77 ± 17 | 0.03 |
|------------------|---------|---------|---------|-----|
| PR duration (ms) | 162 ± 49 | 172 ± 29 | 160 ± 52 | 0.18 |
| QRS duration (ms) | 92 ± 20 | 84 ± 11 | 94 ± 21 | <0.01 |
| QRS axis (°)     | 17.3 ± 41.5 | 27.0 ± 25.0 | 15.0 ± 44.4 | 0.03 |
| Right BBB n (%)  | 11 (5.6) | 1 (2.6)  | 10 (6.3) | 0.70 |
| Left BBB n (%)    | 6 (3.0)  | 0 (0)    | 6 (3.8)  | 0.60 |
| Electrical LVH n (%) | 33 (16.8) | 5 (12.8) | 28 (17.7) | 0.46 |
| QTc duration (ms) | 424 ± 32 | 412 ± 22 | 427 ± 34 | <0.001 |

**Abbreviations:** BBB, bundle branch block; CABG, coronary artery bypass graft; CCB, calcium channel blocker; DBP, diastolic blood pressure; ICD, implantable cardiac defibrillator; MRA, mineralocorticoid receptor antagonist; PCI, percutaneous coronary intervention; SBF, systolic blood pressure; SCD, sudden cardiac death.

*Atrophic ventricular, ICD, Valvular heart disease, Ventricular tachycardia.

Table 4 | Multivariate logistic regression analyses for the predictors of ER.

| OR (95% CI) | p    |
|------------|------|
| Age        | 0.98 (0.96, 1.01) | 0.20 |
| COPD       | 0.00 (0.00, 0.00) | 1.00 |
| Anti-aldosterone | 7.95 (0.40, 158.48) | 0.18 |
| Heart rate | 0.98 (0.95, 1.00) | 0.76 |
| PR interval | 1.01 (1.00, 1.02) | 0.28 |
| QRS duration | 0.97 (0.94, 0.99) | 0.01 |
| Dialysis   | 0.55 (0.24, 1.27) | 0.16 |

**FIGURE 2** | Kaplan Meier Curve comparing 1-year survival in CKD patients with ER, without ER, and the renal transplant donors (RTD).
Electrocardiographic early repolarization in CKD
