Abstract

We study the heavy quark symmetry with the homogeneous bag model (HBM) and light-front quark model (LFQM) based on the decays of $\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell$ ($\ell = e, \mu, \tau$). In particular, we calculate various parameters in the heavy quark expansions, including the Isgur-Wise functions and their first order corrections. The parameters in the HBM are fitted from the mass spectra, while the ones in the LFQM are tightly constrained by the heavy quark symmetry, granting the predictive power of our results. We explicitly obtain that $\mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ e^- \bar{\nu}_e) = (5.69 \pm 0.58, 5.35 \pm 0.50)$, $\mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \mu^- \bar{\nu}_\mu) = (5.67 \pm 0.58, 5.33 \pm 0.49)$, and $\Gamma(\Lambda_b^0 \rightarrow \Lambda_c^+ \tau^- \bar{\nu}_\tau)/\Gamma(\Lambda_b^0 \rightarrow \Lambda_c^+ \mu^- \bar{\nu}_\mu) = (0.3243 \pm 0.0126, 0.3506 \pm 0.0046)$ for the numerical values of (HBM, LFQM). Our results of the branching fractions in both models agree well with the experimental data and lattice QCD calculations. In addition, we find that the hard gluon corrections decrease the branching fractions around 10%.

I. INTRODUCTIONS

Testing the lepton universality via beauty quark decays has raised great interest in both theories and experiments [1–8]. Recently, the LHCb collaboration has reported the ratio of

$$R_{\Lambda_c} = \frac{\mathcal{B}(\Lambda^0_b \to \Lambda_c^+ \tau^- \tau^+)}{\mathcal{B}(\Lambda^0_b \to \Lambda_c^+ \mu^- \mu^+)}$$

given by [9, 10]

$$R_{\Lambda_c} = 0.242 \pm 0.026 \pm 0.040 \pm 0.059,$$  \hspace{1cm} (1)

where the first and second uncertainties are systematic and statistical in \(\mathcal{B}(\Lambda^0_b \to \Lambda_c^+ \tau^- \tau^+)\), and the third one comes from \(\mathcal{B}(\Lambda^0_b \to \Lambda_c^+ \mu^- \mu^+)\), respectively. On the other hand, the lattice quantum chromodynamics (LQCD) gives a slightly larger ratio [11, 12]. The results along with the meson versions are summarized in FIG. 1 with

$$R_{D^{(*)}} = \frac{\Gamma(B \to D^{(*)} \tau^- \tau^+)}{\Gamma(B \to D^{(*)} \tau^- \tau^+)}$$ \hspace{1cm} [13, 14]. Notice that the experimental values of \(R_{D^{(*)}}\) are larger than the theoretical ones in contrast to \(R_{\Lambda_c}\).

On the theoretical side, the form factors of \(\Lambda^0_b \to \Lambda_c^+\) provide ideal playgrounds for quark models. The main reason is that at the massless limit of \((u, d)\), there are only two energy scales in \(\Lambda_Q\) with \(Q = (b, c)\), given by

$$\bar{\Lambda} = \lim_{m_Q \to \infty} (M_Q - m_Q) \hspace{1cm} \varepsilon_Q = \bar{\Lambda}/2m_Q \ll 1,$$ \hspace{1cm} (2)

where \(M_Q\) and \(m_Q\) are the heavy baryon and quark masses, respectively. As \(\varepsilon_Q\) are tiny, the physical quantities are Taylor-expanded regarding to \(\varepsilon_Q\), namely the heavy quark expansion (HQE).

![FIG. 1. The ratios of \(R_D\), \(R_{D^*}\) and \(R_{\Lambda_c}\) in the experiments and LQCD.](image-url)
We take the Isgur-Wise function as an illustration, given as

\[ \bar{\xi}(\omega) = \xi(\omega) + (\varepsilon_b + \varepsilon_c)\xi_{ke}(\omega) + \mathcal{O}(\varepsilon^2) , \]

where \( \xi(\omega) \) is the Isgur-Wise function, \( \xi_{ke}(\omega) \) is the first order correction, and \( \omega = v_b \cdot v_c \) with \( v_Q \) the 4-velocities of \( \Lambda_Q \). As we will see in the next section, \( \bar{\xi}(\omega) \) governs the recoil effects of the form factors. Although the experiments can probe \( \bar{\xi}(\omega) \) only, Eq. (3) allows us to compare \( \xi(\omega) \) and \( \xi_{ke}(\omega) \) separately among the quark models, without the dependence of the quark masses.

In this work, we take the homogeneous bag model (HBM) and light-front quark model (LFQM) to illustrate the heavy quark symmetry. These models are unimpressive but interesting in different aspects. On the one hand, the HBM is a relativistic quark model, in which \( u \) and \( d \) quarks can be safely taken as massless, and the parameters are fitted from the mass spectra. It is reliable at the zero recoil point (\( \omega = 1 \)), but unequal time commutators are needed for a boosted state, causing several uncertainties as \( \omega \) goes up. On the other, the LFQM describes the bound state in a frame-independent way, in which only the relative motions between the constituents are required [15–25]. The Lorentz boosts in the front form are generated by the kinematical operators, which leave the \( x^+ = 0 \) plane invariant [26, 27], so the unequal time commutation relations are not needed. However, the LFQM suffers the uncertainties from the parameters input. In addition the Z-graph contributions forbid us from computing the form factors in the time-like region [28–34]. We will show that these aforementioned difficulties are resolved by the heavy quark symmetry.

This paper is organized as follows. We present the formalism of the HBM and LFQM in Sec. II. The numerical results are given in Sec. III. Sec. IV is the conclusion.

II. FORMALISM

We briefly review some of the results of the HQE, where the details can be found in Ref. [12]. In the heavy quark system, there are two popular parametrizations for
the form factors, given as
\[
\langle \Lambda_c^+ | \bar{c} \gamma^\mu (1 - \gamma_5) b | M_b \rangle = \pi_c \left[ (F_1^V(\omega) \gamma^\mu + F_2^V(\omega) v^\mu_b + F_3^V(\omega) v^\mu_c) - (F_1^A(\omega) \gamma^\mu + F_2^A(\omega) v^\mu_b + F_3^A(\omega) v^\mu_c) \gamma_5 \right] u_b \\
= \overline{u}_c \left[ (f_1(q^2) \gamma^\mu - f_2(q^2) \frac{i \gamma^\mu q^\nu}{M_b} + f_3(q^2) \frac{q^\mu}{M_b}) \right. \\
- \left. (g_1(q^2) \gamma^\mu - g_2(q^2) \frac{i \sigma^{\mu\nu} q^\nu}{M_b} + g_3(q^2) \frac{q^\mu}{M_b}) \gamma_5 \right] u_b,
\]
where \( q = p_b - p_c \), and \( p_b \) and \( p_c \) are the four momenta of \( \Lambda_b^0 \) and \( \Lambda_c^+ \), respectively. From \( p_Q = m_Q v_Q \), it is straightforward to show that \( q^2 = M_b^2 + M_c^2 - 2M_b M_c \omega \). Two sets of parametrizations are related as
\[
f_1 = F_1^V + \frac{M_+}{2M_b} F_2^V + \frac{M_+}{2M_c} F_3^V, \quad f_{2,3} = \pm \frac{1}{2} F_2^V - \frac{M_b}{2M_c} F_3^V, \\
g_1 = F_1^A - \frac{M_-}{2M_b} F_2^A - \frac{M_-}{2M_c} F_3^A, \quad g_{2,3} = \mp \frac{1}{2} F_2^A - \frac{M_b}{2M_c} F_3^A,
\]
with \( M_\pm \equiv M_b \pm M_c \).

At the zero-recoil point of \( \omega = 1 \), the form factors are simply written as
\[
F_1^V(1) = 1 + \varepsilon_b + \varepsilon_c + \varepsilon_c^2 (b_1 - b_2), \quad F_1^A = 1 + \varepsilon_c^2 b_1, \\
F_2^V(1) = F_2^A(1) = -\varepsilon_c + 2\varepsilon_c^2, \quad F_3^V(1) = \mp \varepsilon_b,
\]
to the precision of \( \mathcal{O}(\varepsilon_b \varepsilon_c) \), providing that hard gluon corrections are absent. A great advantage in the heavy quark system is that the recoil effects are taken account by a single function of \( \xi(\omega) \), i.e.
\[
F_{1,2,3}^{V,A}(\omega) = \xi(\omega) F_{1,2,3}^{V,A}(1).
\]

After including the hard gluon corrections shown in FIG. the form factors receive several corrections, given by
\[
F_1^V(\omega) = \frac{\xi(\omega)}{\xi(\omega)} = 1 + \hat{a}_s C_{V_1} + \varepsilon_c + \varepsilon_b + \hat{a}_s \left[ C_{V_1} + 2(\omega - 1)C'_{V_1} \right] (\varepsilon_c + \varepsilon_b) + \varepsilon_c^2 (b_1 - b_2), \\
F_2^V(\omega) = \frac{\xi(\omega)}{\xi(\omega)} = \hat{a}_s C_{V_2} - \frac{2\varepsilon_c}{\omega + 1} + \hat{a}_s \left\{ C_{V_2} \frac{3\omega - 1}{\omega + 1} \varepsilon_b - [2C_{V_1} - (\omega - 1)C_{V_2} + 2C_{V_3}] \frac{\varepsilon_c}{\omega + 1} + 2(\omega - 1)C'_{V_2} (\varepsilon_c + \varepsilon_b) \right\} + \varepsilon_c^2 b_2,
\]
\[
\frac{F_3^V(\omega)}{\xi(\omega)} = \hat{\alpha}_s C_{V3} - \frac{2\varepsilon_b}{\omega + 1} + \hat{\alpha}_s \left\{ C_{V3} \frac{3\omega - 1}{\omega + 1} \varepsilon_c - [2C_{V1} + 2C_{V2} - (\omega - 1)C_{V3}] \frac{\varepsilon_b}{\omega + 1} + 2(\omega - 1)C_{V3}' (\varepsilon_c + \varepsilon_b) \right\},
\]

\[
\frac{F_1^A(\omega)}{\xi(\omega)} = 1 + \hat{\alpha}_s C_{A1} + (\varepsilon_c + \varepsilon_b) \frac{\omega - 1}{\omega + 1} + \hat{\alpha}_s \left[ C_{A1} \frac{\omega - 1}{\omega + 1} + 2(\omega - 1)C_{A1}' \right] (\varepsilon_c + \varepsilon_b) + \varepsilon_c^2 b_1,
\]

\[
\frac{F_2^A(\omega)}{\xi(\omega)} = \hat{\alpha}_s C_{A2} - \frac{2\varepsilon_c}{w + 1} + \hat{\alpha}_s \left\{ C_{A2} \frac{3w + 1}{w + 1} \varepsilon_b - [2C_{A1} - (w + 1)C_{A2} + 2C_{A3}] \frac{\varepsilon_c}{w + 1} + 2(w - 1)C_{A2}' (\varepsilon_c + \varepsilon_b) \right\} + \varepsilon_c^2 b_2,
\]

\[
\frac{F_3^A(\omega)}{\xi(\omega)} = \hat{\alpha}_s C_{A3} + \frac{2\varepsilon_b}{w + 1} + \hat{\alpha}_s \left\{ C_{A3} \frac{3w + 1}{w + 1} \varepsilon_c + [2C_{A1} - 2C_{A2} + (w + 1)C_{A3}] \frac{\varepsilon_b}{w + 1} + 2(w - 1)C_{A3}' (\varepsilon_c + \varepsilon_b) \right\},
\]

where \(\hat{\alpha}_s\) is the strong coupling constant and the definitions of \(C_{A_iV_{1,2,3}}\) can be found in Ref. [12]. To include both soft and hard gluon corrections, we extract the relevant parameters of \(\bar{\xi}(\omega), \bar{\Lambda}\) and \(b_{1,2}\) from the quark models, where the soft gluon (non-perturbative) effects are taken account by the wave functions. After that, we plug the computed parameters into Eq. (8) to contain the hard gluon corrections.

We note that the heavy baryon masses can be expanded as

\[
M_Q = m_Q + \bar{\Lambda} + \frac{\lambda_1}{2m_Q} + \mathcal{O}(\varepsilon_Q^2).
\]

It is convenient to rewrite the binding energy as \(\bar{\Lambda} = CE_{d_i}\), where \(E_{d_i}\) stands for the energy of the diquark system, and \(C\) describes the correction of it in the presence of the heavy quark with an infinite mass.

FIG. 2. The hard gluon corrections of the current operators.
A. Homogeneous bag model

We begin our study with the MIT bag model, of which the quark wave functions of the baryons are confined in a finite region, given as \[36\]

\[
\phi_q(x) = \begin{cases} 
  j_0(p_q r) \chi^\uparrow 
  & \text{for } r \leq R 
  
  i \frac{p_q}{E_k^q + p_q} j_1(p_q r) \hat{r} \cdot \vec{\sigma} \chi^\uparrow 
  & \text{for } r > R 
\end{cases},
\]

for \( r \leq R \),

\[
\phi_q(x) = 0 
\]

with \( r = |\vec{x}| \) and \( R \) the bag radius. Here, \( j_{0,1} \) are the spherical Bessel functions, \( E_k^q = \sqrt{p_q^2 + m_q^2} \) with \( m_q \) and \( p_q \) the quark mass and 3-momentum, and \( \chi^\uparrow = (1, 0)^T \) and \( \chi^\downarrow = (0, 1)^T \) represent a spin-up and a spin-down quarks, respectively. From the boundary condition, \( p_q \) must satisfy \[36\]

\[
\tan(p_q R) = \frac{p_q R}{1 - m_q R + E_k^q R}.
\]

In particular, we have

\[
\lim_{m_{u,d} \rightarrow 0} p_{u,d} = 2.043/R,
\]

and

\[
p_Q = \frac{\pi}{R} \left( 1 - \frac{1}{2m_Q R} \right), \quad E_k^Q = m_Q + \frac{\pi^2}{2m_Q R^2},
\]

to the precision of \( O(1/m_Q^2 R^2) \). It is interesting to point out that the zeroth order corrections are absent in \( E_k^Q \), and the first order corrections correspond to the kinematic energies of the heavy quarks in the nonrelativistic limit. Plugging Eq. \[13\] into the bag wave functions, we are led to

\[
\phi_Q(x) = \begin{pmatrix} 
  j_0(\pi r / R) - \frac{\pi r}{2R^2 m_Q} j_1(\pi r / R) 
  
  i \frac{\pi}{2m_Q R} j_1(\pi r / R) \hat{r} \cdot \vec{\sigma} \chi 
\end{pmatrix} \chi.
\]

On the other hand, the masses of the baryons are given as

\[
M_Q = Z_0/R + \frac{4\pi}{3} R^3 B_0^4 + E_I + \sum q E_k^q,
\]
where \( Z_0 \) and \( B_0 \) are associated with the zero-point and bag volume energies, respectively, \( E_I \) is the interaction energies, and \( R \) minimalizes the baryon masses, given by

\[
\frac{\partial M_Q}{\partial R} = 0. \tag{16}
\]

In calculating the Isgur-Wise function, we do not include the interaction corrections, so we set \( E_I = 0 \) for consistency, which is the major source of errors.

Combining Eqs. (12) and (13), we arrive at

\[
\frac{\partial M_Q}{\partial R} = 4\pi R^2 B_0^4 - (Z_0 + 4.086)/R^2 = 0. \tag{17}
\]

There are two sets of bag parameters in Ref. [36], given as

\[
(Z_0, B_0) = (1.84, 0.145 \text{ GeV}), (1.95, 0.125 \text{ GeV}), \tag{18}
\]

resulting in that

\[
(\Lambda, R^{-1}) = (0.665, 0.223), (0.554, 0.195) \text{ GeV}, \tag{19}
\]

respectively.

The twist is that although the MIT bag model successfully explains most of the low-lying baryon masses, it is difficult to be applied in decays, especially in taking account the recoil effects (\( \omega \) dependencies). The problem can be traced back to that bag states are localized. According to the the Heisenberg uncertainty principle, it can not be an eigenstate of 3-momenta, which is referred to as the center-of-mass motion (CMM) problem. The difficulties were tackled a few years ago in Ref. [37], where localized bags are replaced by linear superpositions of infinite ones, distributed homogeneously all over the space.

In the HBM, the baryon states at rest are given as

\[
|\Lambda_Q, \uparrow\rangle = \int \frac{1}{\sqrt{6}} \epsilon^{\alpha\beta\gamma} d^\dagger_{Qa}(\vec{x}_d) u^\dagger_{bQ}(\vec{x}_u) Q^\dagger_{c\gamma}(\vec{x}_Q) \Psi_{\Lambda_Q}^{abc}(\vec{x}_d, \vec{x}_u, \vec{x}_Q)[d^B\vec{x}]|0\rangle, \tag{20}
\]

where the Greek (Latin) letters represent the color (Dirac spinor) indices, \( \epsilon \) stands for the totally anti-symmetric tensor, \([d^B\vec{x}] = d^B\vec{x}_d d^B\vec{x}_u d^B\vec{x}_Q\), \( q^\dagger \) is the creation operator of
the quark, satisfying
\[
\{ q^\dagger_{d\alpha}(\vec{x}), q_{b\beta}(\vec{x}') \} = \delta_{ab} \delta_{\alpha\beta} \delta^3(\vec{x} - \vec{x}'),
\]  
with \( q \in \{ u, d, Q \} \), and the spatial distributions are described by
\[
\Psi^{abc}_{A_v(duQ)}(\vec{x}_d, \vec{x}_u, \vec{x}_Q) = \frac{N_Q}{\sqrt{2}} \int \left[ \phi^a_{d\uparrow}(\vec{x}_d - \vec{x}_\Delta) \phi^b_{u\uparrow}(\vec{x}_u - \vec{x}_\Delta) \right. \\
\left. - \phi^a_{d\downarrow}(\vec{x}_d - \vec{x}_\Delta) \phi^b_{u\downarrow}(\vec{x}_u - \vec{x}_\Delta) \right] \phi^c_{Q\uparrow}(\vec{x}_Q - \vec{x}_\Delta) d^3\vec{x}_\Delta,
\]  
where \( N_Q \) are the normalization constants. If not stated otherwise, \( \phi^\dagger_{d\uparrow}(\vec{x}) \) is evaluated at \( t = 0 \) in this work.

In Eq. (22), \( \phi_{Q\uparrow}(\vec{x}_Q - \vec{x}_\Delta) \) represents the quark state in the static bag centering at \( \vec{x}_\Delta \). By carrying out the integral of \( d^3\vec{x}_\Delta \), it is straightforward to see that the baryons are distributed uniformly all over the 3-dimensional space. Therefore, the unwanted CMM is removed. We note that the formula are reduced to the ones of the MIT bag model when the integral of \( d^3\vec{x}_\Delta \) is eliminated.

To get a baryon state with a nonzero momentum, we apply the Lorentz boost to Eq. (20). The transformation rule of the creation operators reads
\[
U_v q^\dagger_{\alpha a}(x^\mu) U_v^{-1} = (S_v)_{ab} q^\dagger_{\alpha b} \left( (\Lambda_v^{-1})^\mu_{\nu} x^\nu \right),
\]  
where \( U_v, S_v, \) and \( \Lambda_v \) are the Lorentz boost operators of states, Dirac spinors, and coordinates, respectively. Without lost of generality, we take the Lorentz boost toward the \( \hat{z} \) direction, resulting in
\[
S_{\pm v} = \begin{pmatrix} a_+ & \pm a_- \sigma_3 \\ \pm a_- \sigma_3 & a_+ \end{pmatrix}, \quad S^2_{\pm v} = \begin{pmatrix} \gamma & \pm \gamma v \sigma_3 \\ \pm \gamma v \sigma_3 & \gamma \end{pmatrix},
\]  
where \( a_{\pm} = \sqrt{\gamma \pm 1} \) and \( \gamma = 1/\sqrt{1 - v^2} \).

From Eq. (23), we see that even if we start with \( t = 0 \), the \( t \)-dependencies of quark states are nevertheless still required. It is due to that the \( t = 0 \) plane is not invariant under Lorentz boosts. Thus, for the state having a Lorentz boost, we have to evaluate the anticommutation relations with unequal times, which can not be treated
perturbatively. To overcome the problem, we utilize that the quark states are energy eigenstates in the bag model, and make the substitution in Eq. (22)

\[
q^a(\vec{x}) = e^{-iE_q^aq^a(t, \vec{x})},
\]

where \(E_q\) are the energies of the quarks. It is clear that we do not consider the interaction energies here, as the quark energies are independent to each other. The reasonable range of \(E_q\) is

\[
\frac{1}{3}M_N < E_q < E^k_0 + \frac{1}{3}(E_0 + E_v),
\]

where \(M_N\) is the neutron mass, \(E_0\) and \(E_v\) are the zero-point and vacuum energies arisen from the bag, respectively, which are allocated evenly among the quarks. In the HBM, Eq. (26) serves as the major source of the uncertainties.

After some algebra, we arrive at

\[
\Psi^{abc}(\vec{x}_1, \vec{x}_2, \vec{x}_3) \rightarrow (S^v_0)(S^v)_{ab}(S^v)_{cc}\Psi^{a'b'c'}(\vec{x}_1, \vec{x}_2, \vec{x}_3),
\]

where \(\vec{x}^v = (x, y, \gamma z)\). From the normalization condition

\[
\langle \Lambda Q, \vec{p}'|\Lambda Q\vec{p}\rangle = \frac{1}{u_0^2}u(2\pi)^3\delta^3(\vec{p} - \vec{p}') ,
\]

we derive that

\[
\frac{\overline{uu}}{N^2} = \int d^3\vec{x}_\Delta \prod_q \int \phi^\dagger_q(\vec{x}_q^+)\phi_q(\vec{x}_q^-)d^3\vec{x}_q ,
\]

where \(\vec{x}_q^\pm = \vec{x}_q \pm \vec{x}_\Delta/2\), and \(\sum_q E_q = M_Q\) has been used.

We adopt the Briet frame so that \(\Lambda^b_0\) and \(\Lambda^c_+\) have opposite velocities. Collecting Eqs. (20), (21) and (27), we find that

\[
\langle \Lambda^+_c(\vec{v})|c\dagger\Gamma b(0)|\Lambda^0_0(-\vec{v})\rangle = N_cN_b \int d^3\vec{x}_\Delta \Gamma_{cb}(\vec{x}_\Delta) \prod_l D^v_l(\vec{x}_\Delta),
\]

along with

\[
\Gamma_{cb}(\vec{x}_\Delta) = \int d^3\vec{x} \phi^\dagger_c(\vec{x} + \frac{1}{2}\vec{x}_\Delta) S_v \Gamma S_{-v} \phi_b(\vec{x} - \frac{1}{2}\vec{x}_\Delta) e^{2iE_{cb}\vec{v}\cdot\vec{x}},
\]

\[
D^v_l(\vec{x}_\Delta) = \frac{1}{\gamma} \int d^3\vec{x} \phi^\dagger_l(\vec{x} + \frac{1}{2}\vec{x}_\Delta) \phi_l(\vec{x} - \frac{1}{2}\vec{x}_\Delta) e^{-2iE_l\vec{v}\cdot\vec{x}}, \quad l = u, d,
\]
where $\Gamma$ is an arbitrary Dirac matrix, $E_{di} = E_u + E_d$, and $\omega = \gamma^2(1 + v^2)$. In general, $\Gamma_{cb}$ and $D_i^v$ would be some complicated functions of the quark masses and bag radius. To examine the model, we take $\vec{v} \to 0$ and Taylor-expand the formulae regarding to $M_Q$, leading to

$$
\frac{1}{N_c^2} = 16\pi^2 \int (D_i^0(r_\Delta))^2 r_\Delta^2 dr_\Delta \int_0^{R^2-r_\Delta^2/4} d\rho \int_0^{\sqrt{R^2-r_\Delta^2/4-r_\Delta/2}} dz j_0^+ j_0^- ,
$$

with the abbreviations of $j_{0,1}^\pm = j_{0,1}(\pi r/\Delta)$, $r_\pm = |\vec{x} \mp \vec{x}_\Delta|/2$ and $r_\Delta = |\vec{x}_\Delta|$. In addition, with $m_{u,d} \to 0$, we are led to

$$
D_i^0(r_\Delta) = 4\pi \int_0^{\sqrt{R^2-r_\Delta^2/4}} d\rho \int_0^{\sqrt{R^2-r_\Delta^2/4-r_\Delta/2}} dz \left[ l_0^+ l_0^- + (r^2 - r_\Delta^2/4) l_1^+ l_1^- \right],
$$

where $l_{0,1}^\pm = j_{0,1}(2.043r_\pm/\Delta)$.

The form factors of $F_1^V$ and $F_1^A$ are extracted by

$$
F_1^V(1) = \lim_{v \to 0} \frac{1}{v} \langle \Lambda_c^+ | (\bar{c} \gamma^i b) | \Lambda_0^+ \rangle (0) | \Lambda_c^+ \rangle | (\bar{c} \gamma^i b) | \Lambda_0^+ \rangle (0) | \Lambda_c^+ \rangle | (-\bar{v}) \rangle ,
F_1^A(1) = \lim_{v \to 0} \langle \Lambda_c^+ | (\bar{c} \gamma^i b) | \Lambda_0^+ \rangle (0) | \Lambda_c^+ \rangle | (\bar{c} \gamma^i b) | \Lambda_0^+ \rangle (0) | \Lambda_c^+ \rangle | (-\bar{v}) \rangle ,
$$

resulting in that

$$
F_1^V(1) = 1 + \left( \frac{1}{2m_c} + \frac{1}{2m_c} \right) E_{di} N_c^2 4\pi \int r_\Delta^2 dr_\Delta C(r_\Delta) (D_i^0(r_\Delta))^2,
F_1^A(1) = 1 ,
$$

where

$$
C(r_\Delta) = \frac{4\pi^2}{3R} \int_0^{\sqrt{R^2-r_\Delta^2/4}} d\rho \int_0^{\sqrt{R^2-r_\Delta^2/4-r_\Delta/2}} dz \left[ \left( j_0^+ j_1^- - j_0^- j_1^+ \right) \frac{1}{r_-} \right] r^2
+ \left( j_0^- j_1^+ r_\Delta z + j_0^+ j_1^- \frac{r_\Delta z}{2r_-} \right) ,
$$

to the precision of $O(1/m_c^2 R^2)$. By matching it with Eq. (6), we find that the first order correction of $F_1^A$ indeed vanishes, and

$$
C = N_c^2 4\pi \int r_\Delta^2 dr_\Delta C(r_\Delta) (D_i^0(r_\Delta))^2 = 1 ,
$$

1 In the calculation of the form factors, we have taken the normalization of $\pi_{Qc}^u Q = 1$. 
which holds exactly by an actual calculation. It is a sensible result, since the zeroth order corrections of $E_Q^k$ are absent as shown in Eq. (13), and the interactions among quarks are omitted. We conclude that the diquark energies are unaffected by the presence of the heavy quark at the zeroth order, namely $C = 1$. However, Eq. (31) itself is a nontrivial result, and it indicates that our treatments for the CMM are self-consistent.

We emphasize that Eq. (37) is a parameter-independent result, which can be shown explicitly by changing the variables

$$(\rho, z, \vec{x}_\Delta) \rightarrow \left( \frac{\rho}{R}, \frac{z}{R}, \frac{\vec{x}_\Delta}{R} \right) , \quad (38)$$

in Eqs. (36) and (37). To take account the recoil effects, we use the following trick

$$\xi(\omega) = \sum_{i=1,2,3} F^V_i(\omega) \bigg|_{\varepsilon_Q=0} , \quad \xi_{ke}(\omega) = \frac{\partial}{\partial \varepsilon_c} \left( \sum_{i=1,2,3} F^V_i(\omega) \right) \bigg|_{\varepsilon_Q=0} , \quad (39)$$

where $\sum_i F^V_i$ is evaluated by taking $\Gamma = 1$ in Eq. (31). Consequently, we get

$$\xi(\omega) = N^2 \int d^3 \vec{x}_\Delta d^3 \vec{x} \left( j^+_0 j^-_0 \right) e^{2iE_{di} \vec{v} \cdot \vec{x}} (D_0^l(\vec{x}_\Delta))^2 ,$$

$$\xi_{ke}(\omega) = A(\vec{v}) \Lambda - A(0) \Lambda ,$$

$$A(\vec{v}) \equiv \frac{\pi N^2}{R^2} \int d^3 \vec{x}_\Delta d^3 \vec{x} \left( r^- j^+_0 j^-_0 + r^+ j^+_1 j^-_0 \right) e^{2iE_{di} \vec{v} \cdot \vec{x}} (D_0^l(\vec{x}_\Delta))^2 .$$

By taking $\vec{v} = 0$, we get that $\xi(1) = 1$ and $\xi_{ke}(1) = 0$ as demanded by the Luke’s theorem.

Similarly, the first order corrections of $b_2$ and $b_1$ are obtained, given by

$$\frac{\partial^2 F^V_1(1)}{\partial \varepsilon_c^2} \bigg|_{\varepsilon_Q=0} = (b_1 - b_2) ,$$

$$\frac{\partial^2 F^V_2(1)}{\partial \varepsilon_c^2} \bigg|_{\varepsilon_Q=0} = b_1 , \quad \frac{\partial^2 F^{V,A}_2(1)}{\partial \varepsilon_c^2} \bigg|_{\varepsilon_Q=0} = b_2 . \quad (41)$$
The operations can be easily done by a computer program. However, their expressions are much more complicated and lengthy as well, so we do not list them out here. As a cross check, we compute
\[
\frac{\partial^2}{\partial \varepsilon^2} \left( F_1^V(\omega) - F_1^A(\omega) + F_2^{V,A}(\omega) \right) \bigg|_{\varepsilon_Q=0},
\]
which is indeed found to be zero, consistent with Eq. (42).

We note that \( \xi, \xi_{ke} \) and \( b_{1,2} \) depend only on \( E_{di} R \), which is the only dimensionless parameter. To be specific, they are invariant under the transformation of \((R, E_{di}) \rightarrow (a^{-1} R, a E_{di})\), where \( a \) is an arbitrary constant. For a practical purpose, we can fix \( R \) and vary \( E_{di} \) solely to cover the model uncertainties on \( \Lambda, \xi, \xi_{ke} \) and \( b_{1,2} \).

### B. Light-front quark model

In the LFQM, the baryon states are expressed as
\[
|\Lambda_Q, \uparrow\rangle = \int \frac{1}{\sqrt{6}} \epsilon^{a\beta\gamma} u^+_a(\tilde{p}_u, \lambda_u) d\beta^3(\tilde{p}_d, \lambda_d) Q^\dagger(\tilde{p}_Q, \lambda_Q) \Psi^{[\lambda]}_Q(\tilde{p}_u, \tilde{p}_d, \tilde{p}_Q)[d^3\tilde{p}]|0\rangle,
\]
where \( \Psi^{[\lambda]}_Q(\tilde{p}_u, \tilde{p}_d, \tilde{p}_Q) \) represent the vertex functions between the \( \Lambda_Q \) and \( udQ \), \([\lambda]\) and \([d^3\tilde{p}]\) stand for the light-front helicities \((\lambda_u, \lambda_d, \lambda_Q)\) and light-front 3-momentum integrals \( d^3\tilde{p}_u d^3\tilde{p}_d d^3\tilde{p}_Q \), respectively, and
\[
p_q = (p_q^-, \tilde{p}_q) = (p_q^-, p_q^+, p_q^+) \quad \text{and} \quad d^3\tilde{p}_q = \frac{dp_q^+ dp_q^-}{2(2\pi)^3},
\]
with \( p_q^\pm = p_q^0 \pm p_q^3 \) and \( p_q^\perp = (p_q^1, p_q^2) \). At the equal light-front time \((x^+ = 0)\), the commutation relationships for \( q_a^\dagger(\tilde{p}_q, \lambda_q) \) are
\[
\{ q_a^\dagger(\tilde{p}, \lambda), q_b^\dagger(\tilde{p}', \lambda') \} = \delta_{\lambda\lambda'} \delta_{a\beta} \delta^3(\tilde{p} - \tilde{p}').
\]
Notice that the wave functions are made of position eigenstates in the HBM shown in Eq. (20), whereas they are built out of momentum eigenstates here in contrast.

The vertex functions are further decomposed as
\[
\Psi^{[\lambda]}_Q = 2(2\pi)^3 \frac{1}{\sqrt{P^+}} \delta^3 \left( \tilde{P} - \tilde{p}_u - \tilde{p}_d - \tilde{p}_Q \right) \Phi(\tilde{p}_u, \tilde{p}_d, \tilde{p}_Q) \Xi^{1/2,\dagger}(\lambda_u, \lambda_d, \lambda_Q),
\]
where Φ are the momentum distribution functions of the quarks, Ξ^{1/2,↑} stands for the helicity wave function

\[
Ξ^{1/2,↑}(\lambda_u, \lambda_d, \lambda_Q) = \sum_{s_u,s_d,s_Q} \prod_q (\lambda_q|R_q^\dagger{s_q})(\frac{1}{2}s_u, \frac{1}{2}s_d, \frac{1}{2}s_Q | SS_z),
\]

and \( R_q \) is the Melosh matrix, which brings the quark from its spin state at rest to a light-front helicity state with momentum \( \tilde{p}_q \).  

In this work, we consider the two-particle forces between the quarks, which are effectively described by the harmonic oscillator potentials

\[
V = \beta^4 r^2/(2M),
\]

where \( r \) are the distances of the quarks, and \( M \) and \( \beta \) are the reduced masses and shape parameters, respectively, to be specified later. We take the quarks of \( u \) and \( d \) to form a diquark cluster denoted as \([ud]\), as they are (iso)spin singlet. By integrating out the delta function of \( \delta(\tilde{P} - \tilde{p}_u - \tilde{p}_d - \tilde{p}_Q) \), Eqs. (43) and (46) can be rewritten as

\[
[d^3 \tilde{p}] \rightarrow d^3 \vec{q} d^3 \vec{Q}, \quad \Phi(\tilde{p}_u, \tilde{p}_d, \tilde{p}_Q) \rightarrow \Phi(\vec{q}, \vec{Q})
\]

where \( \Phi(\vec{q}, \vec{Q}) = \phi_{ud} \phi_{Q[ud]} = (\pi \beta_{ud} \beta_{Q[ud]})^{-3/2} \exp\left(-\frac{\vec{q}^2}{2\beta_{ud}^2} - \frac{\vec{Q}^2}{2\beta_{Q[ud]}^2}\right), \)

\( \phi_{ud} \) and \( \phi_{Q[ud]} \) are the wave functions of \((u, d)\) and \((Q, [ud])\), and the shape parameters of \( \beta_{ud} \) and \( \beta_{Q[ud]} \) are the typical relative 3-momenta, respectively. Note that we have projected the light-front 3-momenta to the instant forms by defining

\[
x_Q \equiv \frac{p_Q^+}{P^+} = \frac{E_Q - Q_\perp}{E_{ud} + E_Q}, \quad Q_\perp = x_Q(p_{u\perp} + p_{d\perp}) - (1 - x_Q)p_{Q\perp},
\]

\[
y \equiv \frac{p_u^+}{p_u^+ + p_d^+} = \frac{E_d - q_\perp}{E_u + E_d}, \quad q_\perp = y p_{u\perp} - (1 - y)p_{d\perp},
\]

where \( E_{u,d} = \sqrt{\vec{q}^2 + m^2}, E_Q = \sqrt{\vec{Q}^2 + m_Q^2}, E_{ud} = \sqrt{\vec{Q}^2 + (E_u + E_d)^2} \), and \( m \) stand for the constituent quark masses of \( u \) and \( d \) in the LFQM.

By utilizing that the potentials are independent of quark masses, we find

\[
\beta_{Q[ud]}^4 M_{Q[ud]}^{-1} = \beta_{d[ud]}^4 M_{d[ud]}^{-1} = \beta_{ud}^4 (m/2)^{-1}
\]
where $M_{q[ud]}$ is the reduced effective mass of $q$ and $[ud]$, given as

$$M_{q[ud]}^{-1} = m_q^{-1} + E_{di}^{-1}. \tag{53}$$

The second equality in Eq. (52) comes from the Isgur-Karl model for the equal mass scenario \cite{39}. By considering the well-measured ratio of $g_A/g_V = -1.275$ from the neutron beta decay, we get

$$\beta_{d[ud]} = 0.952m. \tag{54}$$

To the precision of $O(m_Q^{-2})$, we have

$$\beta_{Q[ud]} = \left(1 - \frac{E_{di}}{4m_Q} + O(\frac{1}{m_Q^2})\right) \beta_\infty, \quad \beta_\infty = (1 + E_{di}/m)^{1/4} \beta_{d[ud]}. \tag{55}$$

The existence of the heavy quark limit for $\beta_\infty$ has already been discussed and put by hand in Refs. \cite{17,18}. Here, we provide a clear theoretical background to justify their assumptions.

Now, we are ready to compute $\bar{\Lambda}, b_{1,2,3}, \xi(\omega)$, and $\xi_{ke}(\omega)$. We choose the frame of $q^+ = 0$ to avoid the Z-graph contribution \cite{32}. As $q^2 = q^+q^- - q_{11}^2$, the LFQM is unable to calculate the region of $q^2 > 0$. We set $m_b = m_c/x = m_Q$. At $q^2 = 0$, $\omega$ corresponds to

$$\omega(x) = \frac{M_Q^2 + M_Q^2x}{2M_QM_Qx}, \tag{56}$$

with

$$M_{Q(x)} = (x)m_Q + \bar{\Lambda} + \frac{\lambda_1}{x2m_Q} \tag{57}$$

from Eq. (9), leading to

$$\xi(\omega(x)) = f_1(q^2 = 0, x, \varepsilon\rightarrow 0),$$

$$\left(\frac{1}{x} + 1\right) \xi_{ke}(\omega(x)) = \frac{\partial}{\partial \varepsilon_Q} f_1(q^2 = 0, x, \varepsilon\rightarrow 0). \tag{58}$$

In reality, we have that $x \approx 3$ and $\lambda_1 = -0.5$ GeV$^2$, corresponding to $\omega = 1.43$. The trick is that $\xi(\omega)$ and $\xi_{ke}(\omega)$ are independent of $m_{b,c}$ at a certain value of $\omega$. In the computation, we vary $x$ to compute $\xi(\omega)$ and $\xi_{ke}(\omega)$ at $q^2 = 0$ and get the desired $\omega(x)$.

\footnote{The form factors in the $q^+ = 0$ frame are extracted as Eq. (24) in Ref. \cite{18}.}
For $\Lambda$ and $b_{1,2}$, we again use the trick that they are independent of $m_{b,c}$. We compute them with $x = 1$. Accordingly, $g_1$ and $f_2$ are expanded as

$$g_1 = 1 + \frac{g_1^{(2)}}{m_Q^2} + \mathcal{O}(1/m_Q^3), \quad f_2 = \frac{f_2^{(1)}}{m_Q} + \frac{f_2^{(2)}}{m_Q^2} + \mathcal{O}(1/m_Q^3),$$

(59)

where

$$g_1^{(2)} = -\frac{\beta_2^2}{2}, \quad f_2^{(1)} = \int d^3\bar{q} d^3\bar{Q} |\Phi_\infty|^2 \frac{E_{ud}}{2},$$

$$f_2^{(2)} = \int d^3\bar{q} d^3\bar{Q} |\Phi_\infty|^2 \left[ \frac{E_{ud}}{8\beta_2^2} \left( 7E_{di}\beta_2^2 - 4E_{ud}\beta_2^2 - 2E_{di}Q^2 \right) \right],$$

(60)

and $\Phi_\infty$ is the momentum wave function under the heavy quark limit, given as

$$\Phi_\infty(\bar{q}, \bar{Q}) = (\pi\beta_{ud}\beta_\infty)^{-3/2} \exp(-\frac{-\bar{q}^2}{2\beta_{ud}^2} - \frac{-\bar{Q}^2}{2\beta_{\infty}^2}).$$

(61)

Note that the zeroth order of $g_1$ is consistent with the heavy quark symmetry, which is a nontrivial result.

To match Eqs. (5) and (6) to Eqs. (59) and (60) with $x = 1$, there would be extra crossing terms at the order of $\varepsilon_c\varepsilon_b$ in Eq. (6), which introduce two additional free parameters. To eliminate them, we assume that $F_{V,A}^1(\omega)$ are factorized as

$$F_{V,A}^1(\varepsilon_b, \varepsilon_c, \omega) = f_{V,A}^1(\varepsilon_c, \omega) f_{V,A}^1(\varepsilon_b, \omega),$$

(62)

with $f_{V,A}(\varepsilon_Q, \omega)$ to be determined. Now we have

$$\bar{\Lambda} = 2f_2^{(1)}, \quad \bar{b}_1 = 2g_1^{(2)}, \quad \bar{b}_2 = 2(f_2^{(1)})^2 - 4f_2^{(2)} + 2g_1^{(2)},$$

(63)

where $\bar{b}_{1,2} \equiv b_{1,2}\bar{\Lambda}^2$.

From Eqs. (52), (60) and (61), we see that $f_2^{(1)}$ depends only on $E_{di}$ and $m$. We arrive at

$$f_2^{(1)}(E_{di}, m) = E_{di}F(E_{di}, m) = E_{di}F\left( \frac{E_{di}}{m} \right),$$

(64)

where $F$ is a function to be determined, and the second equality comes from that $F$ can only depends on the dimensionless quantities, i.e. $E_{di}/m$ in this case. By demanding the heavy quark limit of $\bar{\Lambda} = E_{di}$ or equivalently $F = 1/2$, we find

$$E_{di} = 3.293m.$$  

(65)
Collecting Eqs. (52), (60), (61) and (65), we see that only \( m \) remains unfixed.

The twist is that \( m \) is canonically dimensional-one, whereas except for \( \Lambda \), all the other HQE parameters are dimensionless. It turns out that \( \xi, \xi_{ke} \) and \( b_{1,2} \) can not depend on \( m \), so they are parameter-independent results from the LFQM. Explicitly, we have

\[
\begin{align*}
    b_1 &= -0.173, \\
    b_2 &= 0.518, \\
\end{align*}
\]

while \( \xi \) and \( \xi_{ke} \) are shown in FIG. 3

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig3.png}
\caption{The Igure-Wise function and its first order correction from the LFQM.}
\end{figure}

**III. NUMERICAL RESULTS**

In both of the models, \( m_{b,c} \) are taken as the pole quark masses with \( m_{b,c} = (4.78, 1.655) \) GeV, and the adopted value of the Cabibbo-Kobayashi-Maskawa (CKM) matrix element is \( |V_{cb}| = (42.2 \pm 0.7) \times 10^{-3} \) from the inclusive semileptonic \( B \) decays \[40\]. The formalism of the decay widths can be found in Ref. \[41\].

For the HBM, we fix \( R = 4.8 \) GeV\(^{-1} \) without lost of generality as explained in the end of Sec. \[1A\]. From Eq. (26), the reasonable range of \( E_{di} \) is then given as

\[
0.585 \text{ GeV} < E_{di} < 0.686 \text{ GeV},
\]

which is consistent with Eq. (19). For the LFQM, we take \( m = 0.30 \pm 0.08 \) GeV, which is consistent with the experiments of the nucleon magnetic moments and \( B(\Lambda_b^0 \rightarrow \)
\[\Lambda \gamma = (7.1 \pm 1.7) \times 10^{-6} \text{[40, 42]}\]. To be conservative, we allow \(m\) to vary in a wide range, which shall cover all the reasonable values.

The HQE parameters are computed with the formula given in Sec. II. The Isgur-Wise function and its first order correction of the HBM are given in FIG. 4. Notice that the region of \(\omega > 1.43\) is equivalent to \(q^2 < 0\) and thus it is irrelevant to \(\Lambda_b \rightarrow \Lambda_c^+ \ell^- \nu_\ell\). Nevertheless, we have plotted them in the figures to see the dependencies in the high \(\omega\) region, as they are physical in the scattering processes.

To compare the results with those in the literature, we expand the Isgur-Wise function regarding to \(\omega\) to the fourth order, given as

\[\xi(\omega) = 1 + \xi^{(1)}(\omega - 1) + \frac{1}{2!}\xi^{(2)}(\omega - 1)^2 + \frac{1}{3!}\xi^{(3)}(\omega - 1)^3 + \frac{1}{4!}\xi^{(4)}(\omega - 1)^4.\] (68)

The numerical results along with those in the literature are collected in TABLE I. In the literature, Ref. [12] fits the HQE parameters from the experimental data [10] and LQCD calculations [11], Ref. [43] adopts the relativistic quark model (RQM), Refs. [47, 48] employ the light-cone sum rule (LCSR), Ref. [46] also considers the LFQM with parameters fitted from the mass spectra, and Ref. [44] utilizes the QCD sum rule (QCDSR).

Surprisingly, the results in the HBM and LFQM agree well with each other, even though they are two very different quark models. Our values of \(\xi^{(1)}\) also agree well with those from the LHCb and LQCD, but significantly larger than the results from the RQM and QCDSR. Note that in Ref. [12], \(\xi^{(3)}\) and \(\xi^{(4)}\) have been omitted. On the
TABLE I. The HQE parameters with $\bar{\Lambda}$ and $\bar{\xi}_{1,2}$ in units of GeV and GeV$^2$, respectively.

| $\bar{b}_1$ | -0.141(1) | -0.181(90) | 0.24(192) | -0.46(15) | |
| $\bar{b}_2$ | 0.351(35) | 0.541(270) | 0.45(188) | -0.39(39) | |

$^a$ Extracted from $M_{\Lambda Q}$, where 0.81(5) means 0.81 ± 0.05

contrary, we find that they are sizable. In particular, $\bar{\xi}^{(3)}$ is opposite in sign and twice larger in comparison to $\bar{\xi}^{(2)}$. Although our results of $\bar{\xi}^{(2)}$ are larger than the values from the LHCb and LQCD, those of $\xi(\omega = 1.43)$ are consistent with them due to the presences of $\bar{\xi}^{(3)}$.

Note that our values of $\bar{b}_{1,2}$ from the LFQM are contaminated by the uncertainties of $\bar{\Lambda}$, but their signs are not. Explicitly, both models give $\bar{b}_1 < 0$ and $\bar{b}_2 > 0$. The predicted sign of $\bar{b}_2$ is opposite to the one of LHCb+LQCD. As the HBM and LFQM show well consistence in all the HQE parameters, we are confident on these results.

To see the hard gluon effects, we adopt two different schemes for the form factors. In the first one, we calculate them directly from the quark models. In the second one, we plug the values of $\bar{\Lambda}$, $b_1$, $b_2$ and $\bar{\xi}(\omega)$ from TABLE I into Eq. (8). The branching fractions along with those in the literature are collected in TABLE II, where the lower and upper columns in the HBM and LFQM for each lepton pair are the values with and without the hard gluon corrections, respectively, which decrease the branching fractions about 10%. The branching fractions in Table II are consistent with the experimental data and the those in literature, where the uncertainties of our results are smaller than
TABLE II. The branching fractions of $\Lambda^0_b \rightarrow \Lambda^+_c \rightarrow \ell^- \nu_{\ell}$ in units of $\%$, where the lower and upper columns in the HBM and LFQM for each lepton pair correspond to the values with and without the hard gluon corrections, respectively.

| $e^- \bar{\nu}$ | 0.3154(109) 0.3457(70) | 0.3328(102) |              | 0.242(76) | 0.30(9) | 0.292     |
| $\mu^- \bar{\nu}$ | 0.3243(126) 0.3506(46) | 0.3237(36) |              |           |           |           |

those of other approaches with uncertainties provided.

To further test the lepton universality, we compute the ratio of $R_{\Lambda_c}$, given in TABLE III and FIG. 5 where $R_{\Lambda_c}(\text{LQCD})$ come from two different works, in which the upper column is purely from the LQCD calculations [11], while the lower column corresponds to the one which the heavy quark symmetry is imposed to lower the uncertainties [12]. The predictions of the HBM fit well with the experimental data, but the ones of the LFQM disagree with the LHCb results in contrast.

IV. CONCLUSION

We have examined the heavy quark symmetry in the HBM and LFQM. The inputs of the HBM are fixed from the mass spectra, while the parameters in the LFQM are tightly constrained by the heavy quark symmetry. We have demonstrated that the two
models all respect the heavy quark symmetry.

The HQE parameters of $\bar{\Lambda}, b_{1,2}, \xi(\omega)$ and $\xi_{ke}(\omega)$ have been computed. Our results of $\bar{\Lambda}, \xi(\omega)$ and $b_1$ are compatible with those in the literature, but the sign of $b_2$ is opposite comparing to the LHCb+LQCD results. Explicitly, we have shown that $(b_1, b_2) = (-0.173, 0.518)$ from the LFQM, and $(\bar{b}_1, \bar{b}_2) = (-0.141 \pm 0.001, 0.351 \pm 0.035)$ from the HBM in units of GeV$^2$.

We have also calculated $B(\Lambda_b^0 \to \Lambda_c^+ \ell^- \bar{\nu}_\ell)$ and $R_{\Lambda_c}$ with and without the hard gluon corrections. We have found that the hard gluon corrections decrease the branching fractions about 10%. Explicitly, we have obtained that $B(\Lambda_b^0 \to \Lambda_c^+ e^- \bar{\nu}_e) = (5.69 \pm 0.58, 5.35 \pm 0.50)$, $B(\Lambda_b^0 \to \Lambda_c^+ \mu^- \bar{\nu}_\mu) = (5.67 \pm 0.58, 5.33 \pm 0.49)$, and $R_{\Lambda_c} = (0.3243 \pm 0.0126, 0.3506 \pm 0.0046)$, for the results of (HBM, LFQM), respectively. Our predicted values of the branching fractions show good consistencies with the experimental data of results $B(\Lambda_b^0 \to \Lambda_c^+ e^- \bar{\nu}_e, \tau^- \bar{\nu}_\tau) = (6.2^{+1.4}_{-1.3}, 1.5 \pm 0.4)\%$.
