Regularity of the Hamiltonian along Optimal Trajectories

M. Palladino and R. B. Vinter∗

December 30, 2019

Abstract
This paper concerns state constrained optimal control problems, in which the
dynamic constraint takes the form of a differential inclusion. If the differential
inclusion does not depend on time, then the Hamiltonian, evaluated along the
optimal state trajectory and the co-state trajectory, is independent of time. If
the differential inclusion is Lipschitz continuous, then the Hamiltonian, evalu-
ated along the optimal state trajectory and the co-state trajectory, is Lipschitz
continuous. These two well-known results are examples of the following prin-
ciple: the Hamiltonian, evaluated along the optimal state trajectory and the
co-state trajectory, inherits the regularity properties of the differential inclu-
sion, regarding its time dependence. We show that this principle also applies
to another kind of regularity: if the differential inclusion has bounded variation
with respect to time, then the Hamiltonian, evaluated along the optimal state
trajectory and the co-state trajectory, has bounded variation. Two applications
of these newly found properties are demonstrated. One is to derive improved
conditions which guarantee the nondegeneracy of necessary conditions of op-
timality, in the form of a Hamiltonian inclusion. The other application is to
derive new, less restrictive, conditions under which minimizers in the calculus
of variations have bounded slope. The analysis is based on a new, local, concept
of differential inclusions that have bounded variation with respect to the time
variable, in which conditions are imposed on the multifunction involved, only
in a neighborhood of a given state trajectory.

Keywords: Necessary Conditions, Optimal Control, Differential Inclusions, State Constraints.

Consider the optimal control problem

\[
\begin{align*}
(P) \quad & \text{Minimize } g(x(S), x(T)) + \int_S^T L(t, x(t), \dot{x}(t))dt \\
& \text{over absolutely continuous functions } x(.) : [S, T] \to \mathbb{R}^n \text{ s.t.} \\
& \dot{x}(t) \in F(t, x(t)) \text{ a.e., } \\
& x(t) \in A \text{ for all } t \in [S, T] \\
& (x(S), x(T)) \in C,
\end{align*}
\]

the data for which comprises an interval \([S, T]\) \((T > S)\), functions \(g : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}\), \(L : [S, T] \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}\), closed sets \(A \subset \mathbb{R}^n\) and \(C \subset \mathbb{R}^n \times \mathbb{R}^n\) and a multifunction \(F(., .) : [S, T] \times \mathbb{R}^n \rightharpoonup \mathbb{R}^n\). Notice the presence of the pathwise state constraint, \(x(t) \in A\). The state constraint set \(A\) is assumed to have the inequality functional representation:

\[A = \{x \mid h(x) \leq 0\}\]

for some function \(h(.) : \mathbb{R}^n \to \mathbb{R}\). By allowing \(h(.)\) to be a nonsmooth function, we capture within this formulation a wide range of possible state constraints descriptions. An arbitrary closed state constraint set \(A\) is covered by this formulation, since we can always take \(h(x) = d_A(x)\), where \(d_A(.)\) denotes the distance function from the set \(A\) (defined below). But it is convenient to derive necessary conditions directly in terms of \(h(.)\), because practical constraints frequently come in functional inequality form, and it is desirable in such cases to develop analytical tools for analysing the optimal control problem expressed directly in terms of the functions arising from the problem formulation.

A state trajectory \(x(.)\) is an absolutely continuous function that satisfies \(\dot{x}(t) \in F(t, x(t))\), a.e. The state trajectory \(x(.)\) is said to be feasible if \((x(S), x(T)) \in C\) and \(x(t) \in A\) for all \(t \in [S, T]\).

We say that the state trajectory \(\bar{x}(.)\) is a minimizer if it achieves the minimum of \(g(x(S), x(T))\) over all feasible state trajectories \(x(.)\). It is called a \(L^\infty\)-local minimizer if, for some \(\delta > 0\),

\[g(x(S), x(T)) \geq g(\bar{x}(S), \bar{x}(T))\]

for all feasible state trajectories \(x(.)\) such that

\[\|x(.) - \bar{x}(.)\|_{L^\infty} \leq \delta. \tag{1.1}\]

For simplicity in this introduction, though not in the analysis to follow, we assume that \(L(., ., .) \equiv 0\) (no integral cost term).

A variety of sets of necessary conditions of optimality are known, under hypotheses which impose Lipschitz continuity conditions on the data, regarding its \(x\)-dependence, but which require the data to be merely measurable with respect to the \(t\) variable. Typically, these assert the existence of a co-state arc \(q(.)\) satisfying conditions generalizing the Euler-Lagrange equation or Hamilton’s system of equations, the Weierstrass condition and the transversality condition. Relevant references include

\[\text{1 Introduction}\]
(1), (2), (3), (4) (no state constraints), and (5), (6) (when state constraints are present). We refer also to the monographs (7), (8) for expository treatments of this material.

If we additionally hypothesize regularity of $F(t, x)$ with respect to the $t$ variable, then it is possible to extract additional information about optimal trajectories, expressed in terms of the Hamiltonian function:

$$H(t, x, q) = \sup\{q \cdot v | v \in F(t, x)\}.$$

Write $H[.] : [S, T] \rightarrow \mathbb{R}^n$ for the Hamiltonian evaluated along $\bar{x}(.)$ and $p(.)$:

$$H[t] = H(t, \bar{x}(t), p(t)) \quad t \in [S, T].$$

A property of this nature is (9), (10):

(I): ‘$t \mapsto F(., x)$ is constant (for each $x$)’ $\implies$ ‘$H[.]$ is constant’

This condition, which has as precursor the 2nd Erdmann condition in the Calculus of Variations, is referred to as the ‘constancy of the Hamiltonian’ condition for autonomous problems.

Now suppose that $F(., x)$ is Lipschitz continuous. Then the optimal control problem can be reformulated as an autonomous problem in which time is interpreted as an additional state variable. Property (I), applied to the reformulated problem, translates into the following information concerning the original problem:

(II): ‘$t \mapsto F(., x)$ is Lipschitz continuous (for each $x$)’ $\implies$ ‘$H[.]$ is Lipschitz continuous’

The latter property is unremarkable, when the state constraint is absent (i.e. $A = \mathbb{R}^n$) since, in this case, $q(.)$ is Lipschitz continuous, and the Lipschitz continuity of $t \mapsto H[.]$ can be deduced directly from the Lipschitz continuity of $F(., x)$. But the Lipschitz continuity of $H[.]$ is perhaps an unexpected property, when the state constraint is present, since, in this setting, the costate arc $q(.)$ can be discontinuous.

This brings us to the central question addressed in this paper. Can properties (I) and (II) be interpreted as part of a general principle (Q)?

(Q): ‘$H[.]$ inherits the regularity of $F(., x)$’.

The main contribution of this paper is to extend this principle to a larger regularity class. Specifically

(i): We show that if $F(., x)$, has bounded variation, then $H[.]$ also has bounded variation.

(ii): We relate the cumulative variation function of the $H[.]$ to that of the data.
We make two applications of these regularity properties of the Hamiltonian, first, to derive new, less restrictive conditions under which necessary conditions of optimality, in the form of Clarke’s Hamiltonian inclusion, are nondegenerate and, second, establish boundedness of the derivatives of optimal state trajectories, under hypotheses that are less restrictive than those earlier imposed.

As a first step we need to make clear the meaning of the statement ‘\( t \to F(t, x) \) has bounded variation’. An obvious approach would be to require

\[
\sup \left\{ \sup_{x \in X_0} \sum_{i=0}^{N-1} d_H(F(t_{i+1}, x), F(t_i, x)) \right\} < \infty,
\]

where the outer supremum is taken over all partitions \( \{t_0 = S, t_1, \ldots, t_N = T\} \) of \([S, T]\). (In this relation, \( d_H(., .) \) denotes the Hausdorff distance between sets, and \( X_0 \) is some suitably large ball in \( \mathbb{R}^n \) containing the values of all state trajectories of interest.)

The concept of a multifunction \( C(,): [S, T] \rightrightarrows \mathbb{R}^n \) of a scalar variable having bounded variation has previously been encountered in connection with Moreau’s ‘sweeping processes’ [16]. A sweeping process is a solution to the differential inclusion

\[
-dx/dt \in N_{C(t)}(x(t)),
\]

in which \( C(,.) \) is a given multifunction of a scalar variable, taking values, closed, convex sets. Here \( N_{C(x)} \) denotes the normal cone from convex analysis. Existence of solutions, in a weak sense, has been established under the hypothesis that \( C(,.) \) has finite retraction, which is the bounded variation property of this paper (for multifunctions which do not depend on \( x \)), when the one-sided distance function (or ‘retraction’) is used to define variation, in place of the Hausdorff distance function.

There is additional novelty in this paper, regarding our methodology for deriving regularity properties of the Hamiltonian, which involves applying necessary conditions for multi-stage optimal control problems for differential inclusions, similar to those first derived by Clarke and Vinter [10], [11]. This is the first instance, to our knowledge, where multi-stage necessary conditions have been used to derive regularity properties of \( H[,] \). As earlier mentioned, the demonstration that \( H[,] \) is Lipschitz continuous when the data is Lipschitz continuous with respect to \( t \) is a straightforward extension of the constancy property of \( H[,] \) for autonomous problems. Demonstrating that \( H[,] \) has bounded variation, and obtaining estimates on the cumulative variation function as is required in some applications, is a much more challenging task. The key idea is to approximate the original optimal control problem with ‘bounded variation’ data, by a multistage autonomous problem (apart from a small perturbation term contributing Lipschitz time dependence). Necessary conditions are derived for the approximating problem, which take account of its autonomous nature, and the desired regularity properties of the Hamiltonian are obtained by passage to the limit. The precise formulation of the approximating problem, and also the convergence analysis, make use of techniques first used by
Arutyunov et al [1], for the derivation of refined necessary conditions of optimality which provide information about minimizers in some circumstances when standard necessary conditions are degenerate.

Notation: For vectors $x \in \mathbb{R}^n$, $|x|$ denotes the Euclidean length. $B$ denotes the closed unit ball in $\mathbb{R}^n$. Given a multifunction $\Gamma(.) : \mathbb{R}^n \rightrightarrows \mathbb{R}^k$, the graph of $\Gamma(.)$, written $\text{Gr} \{ \Gamma(.) \}$, is the set $\{(x, v) \in \mathbb{R}^n \times \mathbb{R}^k \mid v \in \Gamma(x)\}$. Given a set $A \subset \mathbb{R}^n$ and a point $x \in \mathbb{R}^n$, we denote by $d_A(x)$ the Euclidean distance of a point $x \in \mathbb{R}^n$ from $A$:

$$d_A(x) := \inf \{|x - y| \mid y \in A\}.$$ 

Given an interval $I$, we write $\chi_I(t)$ for the indicator function of $I$, which takes values 1 and 0 when $t \in I$ and $t \notin I$, respectively.

A function $r : [S, T] \to \mathbb{R}$ of bounded variation on the interval $[S, T]$ has a left limit, written $r(t^-)$, at every point $t \in (S, T]$ and a right limit, written $r(t^+)$, at every point $t \in [S, T)$. We say $r(.)$ is normalized if it is right continuous on $(S, T]$.

We denote by $\text{NBV}^+[S, T]$ the space of increasing, real-valued, normalized functions $\mu(.)$ on $[S, T]$ of bounded variation, vanishing at the point $S$. The total variation of a function $\mu(.) \in \text{NBV}^+[S, T]$ is written $||\mu||_{\text{TV}}$. As is well known, each point $\mu(.) \in \text{NBV}^+[S, T]$ defines a Borel measure on $[S, T]$. This associated measure is also denoted $\mu$.

We shall use several constructs of nonsmooth analysis. Given a closed set $D \subset \mathbb{R}^k$ and a point $\bar{x} \in D$. The limiting normal cone $N_D(\bar{x})$ of $D$ at $\bar{x}$ is defined to be

$$N_D(\bar{x}) := \left\{ p \mid \exists x_i \xrightarrow{D} \bar{x}, p_i \to p \text{ s.t. } \limsup_{x \to x_i} \frac{p_i \cdot (x - x_i)}{|x - x_i|} \leq 0 \text{ for all } i \in \mathbb{N} \right\}.$$ 

Here, the notation $y' \xrightarrow{D} y$ is employed to indicate that all elements in the convergent sequence $\{y'\}$ lie in $D$.

Take a lower semicontinuous function $f : \mathbb{R}^k \to \mathbb{R} \cup \{+\infty\}$ and a point $\bar{x} \in \text{dom } f := \{x \in \mathbb{R}^k \mid f(x) < +\infty\}$ The limiting subdifferential of $f$ at $\bar{x}$ (termed the subdifferential in [17], [18]) is denoted $\partial f(\bar{x})$:

$$\partial f(\bar{x}) := \left\{ \xi \mid \exists \xi_i \to \xi \text{ and } x_i \xrightarrow{\text{dom } f} \bar{x} \text{ such that } \limsup_{x \to x_i} \frac{\xi_i \cdot (x - x_i) - \varphi(x) + \varphi(x_i)}{|x - x_i|} \leq 0 \text{ for all } i \in \mathbb{N} \right\}.$$ 

For further information, we refer to the monographs [8], [17] and [18].

2 Multifunctions of Bounded Variation

Take a bounded interval $[S, T]$, a compact set $A \subset \mathbb{R}^k$, a multifunction $F(., ., .) : [S, T] \times \mathbb{R}^n \times A \rightrightarrows \mathbb{R}^n$ and a continuous function $\bar{x}(.) : [S, T] \to \mathbb{R}^n$. Generic elements
in the domain of \( F(.,.,.) \) are denoted by \((t, x, a)\).

In this section we define a concept that makes precise the statement ‘\( F(t, x, a) \) has bounded variation with respect to the \( t \) variable, along \( \bar{x}(.) \), uniformly with respect to \( a \in A' \). If \( F(t, x, a) \) is independent of \((x, a)\) and single valued, i.e. \( F(t, x, a) = \{ f(t) \} \) for some function \( f(.) : [S, T] \rightarrow \mathbb{R}^n \), this concept reduces to the standard notion ‘\( f(.) \) has bounded variation’.

For any \( t \in [S, T] \), \( \delta > 0 \) and partition \( \mathcal{T} = \{ t_0 = S, t_1, \ldots, t_{N-1}, t_N = t \} \) of \([S, t]\), define \( I^\delta(\mathcal{T}) \in \mathbb{R}^+ \cup \{ +\infty \} \) to be

\[
I^\delta(\mathcal{T}) := \sum_{i=0}^{N-1} \sup \{ d_H(F(t_{i+1}, x, a), F(t_i, x, a)) \mid x \in \bar{x}([t_i, t_{i+1}]) + \delta B, a \in A \}.
\]

Here, \( \bar{x}([t_i, t_{i+1}]) \) denotes the set \( \{ \bar{x}(t) \mid t \in [t_i, t_{i+1}] \} \).

Take any \( \epsilon > 0 \). Let \( \eta^\delta(.,.) : [S, T] \rightarrow \mathbb{R}^+ \cup \{ +\infty \} \) be the function defined as follows:

\[
\eta^\delta(S) = 0 \quad \text{and, for } t \in (S, T),
\]

\[
\eta^\delta(t) = \sup \left\{ I^\delta(\mathcal{T}) \mid \mathcal{T} \text{ is a partition of } [S, t] \text{ s.t. diam}\{\mathcal{T}\} \leq \epsilon \right\}.
\]

in which

\[
\text{diam}\{\mathcal{T}\} := \sup \{ t_{i+1} - t_i \mid i = 0, \ldots, N - 1 \}.
\]

Now define the functions \( \eta^\delta(.,.) \), \( \eta(.) : [S, T] \rightarrow \mathbb{R}^+ \cup \{ +\infty \} \) to be

\[
\eta^\delta(t) := \lim_{\epsilon \downarrow 0} \eta^\delta(t) \quad \text{for } t \in [S, T] \tag{2.1}
\]

\[
\eta(t) := \lim_{\delta \downarrow 0} \eta^\delta(t) \quad \text{for } t \in [S, T]. \tag{2.2}
\]

**Definition.** Take a set \( A \subset \mathbb{R}^k \), a multifunction \( F(.,.,.) : [S, T] \times \mathbb{R}^n \times A \leadsto \mathbb{R}^n \) and a function \( \bar{x}(.) : [S, T] \rightarrow \mathbb{R}^n \). We say that \( t \rightarrow F(t,.,.) \) has bounded variation along \( \bar{x}(.) \) over \( A \), if the function \( \eta(.) \) given by (2.2) satisfies

\[
\eta(T) < +\infty.
\]

If \( t \rightarrow F(t,.,.) \) has bounded variation along \( \bar{x}(.) \) uniformly over \( A \), we refer to the function \( \eta(.) \) as the cumulative variation function of \( t \rightarrow F(t,.,.) \) along \( \bar{x}(.) \), uniformly over \( A \). We also refer to \( \eta^\delta(.) \) and \( \eta^\delta(.) \) as the \( \delta \)-perturbed cumulative variation function and \((\delta, \epsilon)\)-perturbed cumulative variation function respectively.

If \( F(t, x, a) \) does not depend on \( a \), we omit mention of the qualifier ‘uniformly over \( A' \). A function \( t \rightarrow L(t,.,.) \) is said to have bounded variation along \( \bar{x}(.) \) uniformly over \( A \), if the associated multifunction \( t \rightarrow \{ L(t,.,.) \} \) has this property.

It is clear that, for any \( t \in [S, T], \delta > 0, \delta' > 0, \epsilon > 0, \epsilon' > 0, \)

\[
\delta' \leq \delta \quad \text{and} \quad \epsilon' \leq \epsilon \implies 0 \leq \eta^\delta_{\epsilon'}(t) \leq \eta^\delta_{\epsilon}(t).
\]
(This relation is valid even when \( \eta^\delta_\epsilon(t) = +\infty \), according to the rule \(+\infty \leq +\infty\).
It follows that, for fixed \( \delta > 0 \) and \( t \in [S,T] \), the functions \( \epsilon \to \eta^\delta_\epsilon(t) \) and \( \delta' \to \eta^{\delta'}_\epsilon(t) \)
are monotone increasing and bounded below on \((0,\infty)\). The limits appearing in the
definitions of \( \eta^\delta(.) \) and \( \eta(.) \) (see (2.1) and (2.2)) are therefore well-defined.

Assume that \( t \to F(t,\ldots) \) has bounded variation along \( \bar{x}(.) \), uniformly over \( A \). Then
there exist \( \bar{\delta} > 0 \) and \( \bar{\epsilon} > 0 \) for which \( \eta^\delta_\epsilon(T) < +\infty \). We list further elementary
properties of the accumulative variation functions: for any \( \delta \in (0,\bar{\delta}] \) and \( \epsilon \in (0,\bar{\epsilon}] \),

(a): \( t \to \eta^\delta_\epsilon(t) \), \( t \to \eta^\epsilon_\delta(t) \) and \( t \to \eta(t) \) are increasing, finite valued functions, and
(b): given any \([s,t] \subset [S,T]\) such that \( t - s \leq \epsilon \),
\[
d_H(F(t,y,a),F(s,y,a)) \leq \eta^\delta_\epsilon(t) - \eta^\epsilon_\delta(s),
\]
for all \( y \in \bar{x}(t') + \delta B \), \( t' \in [s,t] \) and \( a \in A \).

As is well known, an \( \mathbb{R}^n \)-valued function of bounded variation on a finite interval
may be discontinuous, but it has everywhere left and right limits and it has at most
a countable number points of discontinuity. Any multifunction having bounded
variation uniformly along a given continuous trajectory has similar properties, as
described in the following proposition, a proof for which appears in the Appendix.

**Proposition 2.1.** Take a compact set \( A \subset \mathbb{R}^k \), a continuous function \( \bar{x}(.) : [S,T] \to \mathbb{R}^n \) and a multifunction \( F(\ldots,\ldots) : [S,T] \times \mathbb{R}^n \times A \to \mathbb{R}^n \) which has bounded variation
along \( \bar{x}(.) \) uniformly over \( A \), and take some \( \bar{\delta} > 0 \) such that \( \eta^\delta_\epsilon(T) < +\infty \). Assume that

(C1) \( F(\ldots,\ldots) \) takes values closed, non-empty sets, \( F(\ldots,x,a) \) is measurable for each
\((x,a) \in \mathbb{R}^n \times A \) and there exists \( c > 0 \) such that
\[
F(t,x,a) \subset cB \text{ for all } x \in \bar{x}(t) + \delta B, \ t \in [S,T], \ a \in A. \tag{2.3}
\]

(C2) There exists a modulus of continuity \( \gamma(.) : \mathbb{R}^+ \to \mathbb{R}^+ \) such that
\[
F(t,x,a) \subset F(t,x',a') + \gamma(|x - x'| + |a - a'|)B \tag{2.4}
\]
for all \( x,x' \in \bar{x}(t) + \delta B \), \( t \in [S,T] \) and \( a,a' \in A \).

Take \( \delta \in (0,\bar{\delta}) \). Then,

(a): For any \( \bar{s} \in [S,T] \) and \( \bar{t} \in (S,T] \), the one-sided limits
\[
F(\bar{s}^+,x,a) := \lim_{s \uparrow \bar{s}} F(s,x,a)
\]
and
\[
F(\bar{t}^-,y,a) := \lim_{t \downarrow \bar{t}} F(t,y,a)
\]
exist for every \( x \in \bar{x}(\bar{s}) + \delta B \), \( y \in \bar{x}(\bar{t}) + \delta B \) and \( a \in A \).
(b): For any \( \bar{s} \in [S,T] \) and \( \bar{t} \in (S,T) \)

\[
\lim_{s \downarrow \bar{s}, x \in \bar{x}(s) + \delta B} \sup_{a \in A} d_H(F(s^+, x, a), F(s, x, a)) = 0
\]

and

\[
\lim_{t' \downarrow t, x \in \bar{x}(t) + \delta B} \sup_{a \in A} d_H(F(t', x, a), F(t, x, a)) = 0
\]

(c): There exists a countable set \( A \) such that, for every \( t \in (S,T) \setminus A \) and \( x \in \bar{x}(t) + \bar{a}B \),

\[
\lim_{t' \to t} \sup_{x \in \bar{x}(t') + B} d_H(F(t', x, a), F(t, x, a)) = 0.
\]

The next proposition, a proof for which appears in the Appendix, relates the cumulative variation function of the multifunction \( F(\cdot, x, a) \) to that of the derived multifunction \( \bar{F}(\cdot, x, a) \), obtained by replacing the end-point values by their left and right limits.

**Proposition 2.2.** Take a compact set \( A \subset \mathbb{R}^k \), a continuous function \( \bar{x}(\cdot) : [S,T] \to \mathbb{R}^n \) and a multifunction \( F(\cdot, \cdot, \cdot) : [S,T] \times \mathbb{R}^n \times A \to \mathbb{R}^n \) which has bounded variation along \( \bar{x}(\cdot) \) uniformly over \( A \). Denote by \( \eta(\cdot) \) its cumulative variation function. Assume that hypotheses (C1) and (C2) of Prop. \( \text{[2.7]} \) are satisfied for some \( \delta > 0 \) such that \( \eta^\delta(T) < +\infty \). Take \( \delta \in (0,\bar{\delta}) \) and let \( \bar{F}(\cdot, \cdot, \cdot) : [S,T] \times \mathbb{R}^n \times A \to \mathbb{R}^n \) be a multifunction such that, for \( (t, x, a) \in [S,T] \times \mathbb{R}^n \times A \),

\[
\bar{F}(t, x, a) = \begin{cases} 
F(S^+, x, a) & \text{if } t = S \text{ and } |x - \bar{x}(S)| \leq \delta \\
F(T^-, x, a) & \text{if } t = T \text{ and } |x - \bar{x}(T)| \leq \delta \\
F(t, x, a) & \text{otherwise} .
\end{cases}
\]

(Note that limit sets \( F(S^+, x, a) \) and \( F(T^-, x, a) \) exist, by the preceding proposition.) Then \( \bar{F}(\cdot, \cdot, \cdot) \) has bounded variation along \( \bar{x}(\cdot) \) and the cumulative variation function \( \bar{\eta}(\cdot) \) is left continuous at \( S \) and right continuous at \( T \) respectively, i.e.

\[
\bar{\eta}(S) = \lim_{s \downarrow S} \bar{\eta}(s) \quad \text{and} \quad \bar{\eta}(T) = \lim_{t \uparrow T} \bar{\eta}(t) .
\]

The cumulative variation function of \( F(\cdot, \cdot, \cdot) \) and \( \bar{F}(\cdot, \cdot, \cdot) \) are related as follows:

\[
\bar{\eta}(t) - \bar{\eta}(s) = \eta(t) - \eta(s) \quad \text{for } [s, t] \subset (S,T) ,
\]

Furthermore,

\[
\lim_{s \downarrow S} \eta(s) - \lim_{s \downarrow S} \bar{\eta}(s) = \sup_{a \in A} \left. d_H(F(S, \bar{x}(S), a), F(S^+, \bar{x}(S), a)) \right|_{s \downarrow S}
\]

and

\[
\lim_{t \uparrow T} \eta(t) - \lim_{t \uparrow T} \bar{\eta}(t) = \sup_{a \in A} \left. d_H(F(T, \bar{x}(T), a), F(T^-, \bar{x}(T), a)) \right|_{t \uparrow T}
\]
The following proposition, a proof for which appears in the Appendix, provides information about how the cumulative variation function of a multifunction \( F(., x, a) \) is affected when the parameter space for \( a \) changes.

**Proposition 2.3.** Take compact sets \( A_1 \subset A \subset \mathbb{R}^k \), a continuous function \( \bar{x}(.) \) and a multifunction \( F(., ., .) : [S, T] \times \mathbb{R}^n \times \mathbb{R}^k \rightharpoonup \mathbb{R}^n \). Assume that \( t \to F(t, ., .) \) along \( \bar{x}(.) \) uniformly over \( A \). Write \( \eta_A(.) \) and \( \eta_{A_1}(.) \) for the cumulative variation functions of \( t \to F(t, ., .) \) with respect to the sets \( A \) and \( A_1 \) respectively. (Since \( t \to F(t, ., .) \) has bounded variation with respect to \( A \), it automatically has bounded variation with respect to the small set \( A_1 \).) Then, for any \( [s, t] \subset [S, T] \),

\[
\eta_{A_1}(t) - \eta_{A_1}(s) \leq \eta_A(t) - \eta_A(s) .
\]  

(2.6)

### 3 Main Results

We refer to the following hypotheses on the data for problem \((P)\) of the introduction, in which \( \bar{x}(.) \) is the \( L^\infty \)-local minimizer of interest and \( \bar{\delta} > 0 \) is some constant:

**\( (H1) \):** \( F(., .) \) takes values closed, non-empty sets. For each \( x \in \mathbb{R}^n \), \( F(., x) \) is a \( \mathcal{L} \) measurable multifunction and \( L(., x, .) \) is a \( \mathcal{L} \times \mathcal{B}^n \) measurable function, where \( \mathcal{L} \) and \( \mathcal{B}^n \) denote the Lebesgue subsets of \([S, T]\) and the Borel subsets of \( \mathbb{R}^n \) respectively. \( g(., .) \) is Lipschitz continuous on \( (\bar{x}(S), \bar{x}(T)) + \bar{\delta} \mathcal{B} \times \mathcal{B} \).

**\( (H2) \):** \( L(., ., .) \) is bounded on bounded sets and there exist \( k > 0 \) and \( c > 0 \) such that

\[
F(t, x) \subset F(t, x') + k(|x - x'|)B \quad \text{and} \quad F(t, x) \in cB
\]

\[
|L(t, x, v) - L(t, x', v)| \leq k|x - x'|
\]

for all \( x, x' \in \bar{x}(t) + \bar{\delta} \mathcal{B} \), \( v \in F(t, x) \), a.e. \( t \in [S, T] \).

**\( (H3) \):** There exists a constant \( k_h \) such that

\[
|h(x) - h(x')| \leq k_h|x - x'|
\]

for all \( x, x' \in \bar{x}([S, T]) + \bar{\delta} \mathcal{B} \).

**\( (H4) \):** \( \{(e, v) \in \mathbb{R}^n \times \mathbb{R} \mid e \in F(t, x), v \geq L(t, x, e)\} \) is a convex set for each \( x \in \mathbb{R}^n \).

Define the Hamiltonian function \( H_\lambda(., ., .) : [0, 1] \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R} \)

\[
H_\lambda(t, x, p) := \max_{v \in F(t, x)} \left[p \cdot v - \lambda L(t, x, v)\right]
\]

(3.1)
and write
\[ \tilde{C} := C \cap \left( \{ x' | h(x') \leq 0 \} \times \{ x' | h(x') \leq 0 \} \right). \]

**Theorem 3.1.** Let \( \bar{x}(.) \) be an \( L^\infty \)-local minimizer for \( (P) \). Assume that hypotheses \( (H1)-(H4) \) are satisfied. Assume also that

(BV):

\[ t \to F(t,.) \text{ has bounded variation along } \bar{x}(.) \]

and

\[ t \to L(t,.,.) \text{ has bounded variation along } \bar{x}(.) \text{ uniformly over } \mathbb{R}, \]

where \( c \) is the constant of hypothesis \( (H2) \). Write \( \eta_F^*(.) \) and \( \eta_L^*(.) \) for the normalized cumulative variation functions of \( F(.,.) \) and \( L(.,.,.) \) respectively, along \( \bar{x}(.) \).

Then there exist an absolutely continuous function \( p(.) : [S,T] \to \mathbb{R}^n \), a function \( \mu(.) \in NBV^+[S,T] \), a \( \mu \)-integrable function \( \gamma(.) \) and \( \lambda \geq 0 \) such that

(i): \( (p(.),\lambda,\mu(.)) \neq (0,0,0) \),

(ii): \( (-\dot{p}(t),\dot{x}(t)) \in \partial_{x,p}H_\lambda(t,\bar{x}(t),q(t)) \text{ a.e.} \),

(iii): \( q(t) \cdot \dot{x}(t) - \lambda L(t,\bar{x}(t),\dot{x}(t)) = \max \{ q(t) \cdot v - \lambda L(t,\bar{x}(t),v) | v \in F(t,\bar{x}(t)) \} \text{ a.e.} \),

(iv): \( (q(S),-q(T)) \in \lambda \partial g(\bar{x}(S),\bar{x}(T)) + N_C(\bar{x}(S),\bar{x}(T)), \)

(v): \( \gamma(t) \in \text{co} \partial^\gamma h(\bar{x}(t)) \text{ } \mu \text{-a.e. } t \in [S,T]. \)

where
\[ q(t) = \begin{cases} p(t) + \int_{[s,t]} \gamma(s) \mu(ds) & \text{if } t \in [S,T) \\ p(T) + \int_{[s,T]} \gamma(s) \mu(ds) & \text{if } t = T. \end{cases} \]

Furthermore, the Hamiltonian evaluated along \( (\bar{x}(.),q(.)) \) has the following properties: there exists a normalized function of bounded variation \( r(.) : [S,T] \to \mathbb{R} \) which is right and left continuous at \( S \) and \( T \) respectively, i.e.

\[ r(S) = \lim_{s \downarrow S} r(s), \quad r(T) = \lim_{t \uparrow T} r(t), \]

such that

(vi): \( |r(t) - r(s)| \leq ||q(.)||_{L^\infty} \times (\eta_F^*(t) - \eta_F^*(s)) + \lambda \times (\eta_L^*(t) - \eta_L^*(s)) \)

for all \( [s,t] \subset (S,T) \),

(vii): \( H_\lambda(t,\bar{x}(t),q(t)) = r(t) \text{ } \mu \text{-a.e. and} \)

(viii): \( r(S) = \lim_{s \downarrow S} H_\lambda(s,\bar{x}(S),p(S)), \quad r(T) = \lim_{t \uparrow T} H_\lambda(t,\bar{x}(T),q(T)). \)
In the theorem statement, the ‘hybrid’ partial subdifferentials $\partial^\infty_x h(x)$ and $\tilde{\partial}_{x,p}H(s,x,p)$ are defined to be:

$$\partial^\infty_x h(x) := \{\xi \mid \exists x_i \to x, \xi_i \to \xi, \text{ s.t. } \xi_i = \nabla_x h(x_i) \text{ and } h(x_i) > 0 \text{ for each } i\}$$

and

$$\tilde{\partial}_{x,p}H(t,x,p) := \limsup_{s \to t} \text{co} \partial_{x,p}H(s,x,p). \quad (3.2)$$

Comments

(a): The standard Hamiltonian inclusion $(-\dot{p}(t), \dot{x}(t)) \in \text{co} \partial_{x,p}H_{\lambda}(t, \bar{x}(t), q(t))$ involving the Clarke subdifferential $\partial_{x,p}H$ implies the Weierstrass condition (iii). When the Hamiltonian inclusion takes the weaker form (ii) involving the hybrid subdifferential $\tilde{\partial}_{x,p}H$, the Weierstrass condition (iii) does not automatically follow and is included in the theorem statement as a separate condition.

(b): Suppose $p(t) + \int_{[S,t]} \nabla h(\bar{x}(s)))ds$ has bounded variation along $\bar{x}(\cdot)$. Then, under hypotheses (H1)-(H4), it is easy to show directly that, for any $p(\cdot), \bar{x}(\cdot) \in W^{1,1}$ and measure $\mu(\cdot)$, the function

$$H(t) := t \to \max\{(p(t) + \int_{[S,t]} \nabla h(\bar{x}(s)))ds) \cdot v \mid v \in F(t, \bar{x}(t))\}$$

also has bounded variation. Notice that, in this simple direct demonstration, the cumulative variation of both $p(t) + \int_{[S,t]} \nabla h(\bar{x}(s)))ds$ and of $p(t) + \int_{[S,t]} \nabla h(\bar{x}(s)))ds$ both contribute to the cumulative variation function of $h(t)$. So the assertion, merely, that the Hamiltonian is of bounded variation is a trivial addition to known necessary conditions. However the theorem contributes the extra information (vi), when may be paraphrased as the assertion: when $(p(\cdot), \mu)$ are multipliers associated with a $L^\infty$ minimizer $\bar{x}(\cdot)$, then the cumulative variation function of $h(\cdot)$ is absolutely continuous with respect to the cumulative variation functions of $t \to F(t,\cdot)$ and $t \to L(t,\cdot)$. This tells, perhaps surprisingly, that only the cumulative variation of $t \to F(t,\cdot)$ and $t \to L(t,\cdot)$, and not that of $p(t) + \int_{[S,t]} \nabla h(\bar{x}(s)))ds$, contribute to the cumulative variation of the Hamiltonian. This is a highly nontrivial addition to the standard necessary conditions, even when there are no state constraints. We investigate implications in the following two sections.

4 Application 1: Minimizer Regularity

Take a function $L : [S,T] \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ and points $x_0, x_1 \in \mathbb{R}^n$. Consider the optimization problem:

$$(Q) \begin{cases} \text{Minimize } \int_{S}^{T} L(t,x(t),\dot{x}(t))dt \\
\text{over absolutely continuous functions } x(\cdot) : [S,T] \to \mathbb{R}^n \text{ s.t. } x(S) = x_0 \text{ and, } x(T) = x_1. \end{cases}$$
In this section we write $H(t,x,p)$ in place of $H_\lambda(t,x,p)$ when $\lambda = 1$, thus

$$H(t,x,p) := \sup\{p \cdot v - L(t,x,v) \mid v \in \mathbb{R}^n\}.$$ 

It is well-known that $(Q)$ has a minimizer $\bar{x}(\cdot)$ under the following hypotheses:

(HE): (i): $L(t,\cdot,\cdot)$ is $\mathcal{L} \times \mathcal{B}^{n \times n}$ measurable, where $\mathcal{L}$ and $\mathcal{B}^r$ denote the Lebesgue subsets of $[S,T]$ and the Borel subsets of $\mathbb{R}^r$ respectively, and $L(t,\cdot,\cdot)$ is lower semicontinuous for each $t \in [S,T]$.

(ii): $L(t,x,\cdot)$ is convex for each $(t,x) \in \mathbb{R}^n$.

(iii): There exists a convex function $\theta(\cdot): \mathbb{R}^+ \to \mathbb{R}^+$ and a number $\alpha$ such that

$$\lim_{r \to \infty} \frac{\theta(r)}{r} = +\infty,$$

and

$$L(t,x,v) \geq \theta(|v|) - \alpha|x| \text{ for all } (t,x,v) \in [S,T] \times \mathbb{R}^n \times \mathbb{R}^n.$$ 

If (HE) is supplemented by the mild regularity hypothesis on $L(t,\cdot,\cdot)$:

(HR): Given any $D > 0$ there exists $k_D > 0$ such that

$$L(t,x,v) - L(t,x',v') \leq k_D(|(x,v)-(x',v')|)$$

for all $(x,v),(x',v') \in D\mathcal{B}, t \in [S,T]$ which permit us to calculate subdifferentials of $L(t,\cdot,\cdot)$ in some sense, then we might expect that the minimizer $\bar{x}(\cdot)$ satisfies standard first order conditions of optimality. This however is not the case. There are counter-examples (3,9) of problems with smooth data, satisfying (HE) and (HR), whose minimizers fail to satisfy the Euler Lagrange equation.

There has been longstanding interest in the question of what additional hypotheses, besides, (HE) and (HR), are required to ensure minimizers satisfy classical necessary conditions (or their modern nonsmooth analogues). In much of this literature, additional hypotheses are imposed to ensure that minimizers are Lipschitz continuous, since the Hamiltonian inclusion (for example) is automatically satisfied by Lipschitz continuous minimizers under (HE) and (HR). One such additional hypothesis (see []) guaranteeing that minimizers are Lipschitz continuous and therefore satisfy necessary conditions of interest is

(HA): $L(\cdot,\cdot,\cdot)$ is locally Lipschitz continuous (in all variables), $L(\cdot,\cdot,\cdot)$ continuously differentiable on a neighborhood of $(t,\bar{x}(t),\dot{\bar{x}}(t))$ for each $(t,x,v) \in (S,T) \times \mathbb{R}^n \times \mathbb{R}^n$, and

$$t \to \nabla_t L(t,\bar{x}(t),\dot{\bar{x}}(t))$$

is integrable.

(For simplicity, we do not state the more complicated form this condition takes, when $L(\cdot,\cdot,\cdot)$ is no longer continuously differentiable.) Hypothesis (HA), or to be
precise the version of it which does not require continuous differentiability, is automatically satisfied when \( L(t, x, v) \) does not depend on \( t \).

The theory of previous sections will permit us to replace the hypothesis (HA) by a weaker hypothesis requiring that \( t \to L(t, ., .) \) is merely of bounded variation is some uniform sense. This new hypothesis covers different cases and it allows \( L(t, ., .) \) to have a countable number of fractional singularities, or even discontinuities. Specifically, we shall assume:

(BV): There exists \( \epsilon > 0 \) and \( \delta > 0 \) and \( K > 0 \) such that, for all partitions \( T = \{ t_0 = S, t_1, \ldots, t_{N-1}, t_N = T \} \) of \([S, T]\) with \( \text{diam}\{T\} \leq \epsilon \), we have

\[
\sum_{i=0}^{N-1} \sup \{ |L(t_{i+1}, x, v) - L(t_i, x, v)| \mid x \in \bar{x}(\{t_i, t_{i+1}\}) + \delta B, v \in \mathbb{R}^n \} \leq K.
\]

(In the language of previous sections, (BV) is the requirement that \( t \to L(t, ., .) \) has bounded variation along \( \bar{x}(.) \) uniformly over the set \( A \), where now \( A \) is the unbounded set \( \mathbb{R}^n \).)

**Proposition 4.1.** Let \( \bar{x}(.) \) be an \( L^\infty \)-local minimizer for (Q). Assume that hypotheses (HE) and (BV) are satisfied. Then \( \bar{x}(.) \) is Lipschitz continuous and there exists a Lipschitz continuous function \( p(.) : [S, T] \to \mathbb{R}^n \) such that

\[
(-\dot{p}(t), \dot{x}(t)) \in \tilde{\partial}_{x,p} H(t, \bar{x}(t), p(t)) \text{ a.e.}
\]

(4.1)

(where the subdifferential \( \tilde{\partial}_{x,p} H(., .) \) is as in (4.2)).

**Proof.** Fix any \( k' > \|\dot{x}(.)\|_{L^\infty([\bar{t}, \bar{t}'; \mathbb{R}^n])} \). Then, under the hypothesis (BV), the function \( t \to L(t, ., .) \) has bounded variation along \( \bar{x} \) uniformly over the compact set \( k'B \). Write the cumulative variation function \( t \to \eta(t; k') \). It is clear from the hypothesis that

\[
\eta(t; k') \leq K \text{ for all } t \in [S, T] \text{ and } k' \geq 0.
\]

This inequality, in which \( K \) is the constant of hypothesis (BV), continues to be satisfied if \( \eta(t; k') \) is replaced by its normalized version \( \eta^*(t; k') \), obtained by replacing values of the function at interior points by their right limits.

We deduce from Tonelli regularity theory (see, e.g., [13, Chapter XX]) that there exists a point \( \bar{t} \in (S, T) \) such that \( \dot{x}(.) \) is essentially bounded on a neighborhood of \( \bar{t} \). We shall show that \( \dot{x}(.) \) is essentially bounded on \( [\bar{t}, T] \). An analogous argument ‘in reverse time’ will tell us that \( \dot{x}(.) \) is essentially bounded also \( [\bar{t}, T] \). It will follow that \( \bar{x}(.) \) is Lipschitz continuous on all of \([S, T]\).

The proof is based on the fact:

If there exists \( \bar{k} \) such that, for any \( [\bar{t}, t'] \subset [\bar{t}, T], \ t' > \bar{t}, \) on which \( \dot{x}(.) \) is essentially bounded, there exists \( p(.) \in W^{1,1}([\bar{t}, T]; \mathbb{R}^n) \) such that

\[
(-\dot{p}(t), \dot{x}(t)) \in \tilde{\partial}_{x,p} H(t, \bar{x}(t), p(t)) \text{ a.e.}
\]

(4.2)

\[
|p(t)| \leq \bar{k} \text{ for all } t \in [\bar{t}, T].
\]
Then \( \hat{x}(\cdot) \) is essentially bounded on \([\bar{t}, T]\).

(This is a slight modification of [18] Lemma 11.4.1, in which the right side of (4.2) is expressed in terms of the hybrid subdifferential \( \partial H \); this makes no essential difference to the proof.)

Take any \([\bar{t}, t'] \subset [\bar{t}, T]\), \( t' > \bar{t} \), on which \( \hat{x}(\cdot) \) is essentially bounded. Now apply Thm. 3.1 to \( \bar{x}(\cdot) \) restricted to \([\bar{t}, t']\), regarded as minimizer for the problem

\[
\text{Minimize } \left\{ \int_{\bar{t}}^{t'} L(s, x(s), \dot{x}(s))ds \mid x(\bar{t}) = \bar{x}(\bar{t}), x(t') = \bar{x}(t') \text{ and } |\dot{x}(\cdot)| \leq k' \right\}.
\]

We deduce the existence of \( p(\cdot) \in W^{1,1} \) and a normalized function of bounded variation (on the interval \([\bar{t}, t']\)) such that

\[
\begin{align*}
-\hat{p}(t), \dot{x}(t) &\in \partial_{x,p} H(t, \bar{x}(t), q(t)) \text{ a.e.} \quad (4.3) \\
r(t) &= \max_{v \in k'B} \{ p(t) \cdot v - L(t, \bar{x}(t), v) \}, \text{ a.e.} \quad (4.4) \\
p(t) \cdot \dot{x}(t) - L(t, x(t), \dot{x}(t)) &\geq p(t) \cdot v - L(t, \bar{x}(t), v) \quad \text{for all } v \in k'B \quad (4.5) \\
r(t) - r(s) &\leq \eta^*(t; k') - \eta^*(s; k') \quad \text{for all } [s,t] \subset [\bar{t}, t'] . \quad (4.6)
\end{align*}
\]

Notice the necessary conditions are stated in ‘normal form’, i.e. with cost multiplier \( \lambda \) set to 1. This is permissible since, for fixed endpoint problems with a dynamic constraint \( \dot{x} \in k'B \) and minimizing arcs \( \bar{x}(\cdot) \) with velocities interior to \( k'B \), the necessary conditions above can only be satisfied by multipliers \( (p(\cdot), \lambda) \) for which \( \lambda > 0 \). We may then arrange \( \lambda = 1 \) by scaling \( p(\cdot) \) and \( \lambda \) appropriately.

Since \( \dot{x}(t) \) interior to \( k'B \) a.e., and \( L(t, \bar{x}(t), \cdot) \) is convex, (4.5) implies the ‘global’ optimality property

\[
p(t) \cdot \dot{x}(t) - L(t, x(t), \dot{x}(t)) \geq p(t) \cdot v - L(t, x(t), v) \quad \text{for all } v \in \mathbb{R}^n, \text{ a.e.} \quad (4.7)
\]

Since, additionally, \( L(t, \bar{x}(t), \cdot) \) is locally Lipschitz continuous, we have

\[
p(t) \in \partial_v L(t, \bar{x}(t), v = \dot{x}(t)) \quad \text{a.e.}
\]

It follows then from hypothesis (HR) that, for some \( t_1 \in (\bar{t}, t') \),

\[
|p(t)| \leq k_1 \quad \text{a.e. } t \in [\bar{t}, t_1] \quad (4.8)
\]

for some \( k_1 > 0 \) that does not depend on \( t' \). We can deduce from (4.4) and (4.8) that

\[
|r(s)| \leq k_2 \quad \text{a.e. } t \in [\bar{t}, t_1] \quad , \quad (4.9)
\]

for some \( k_2 > 0 \) that does not depend on \( t' \). Now write

\[
k_3 := \max_{t \in [\bar{t}, T]} \max_{v \in B} L(t, \bar{x}(t), v) ,
\]

14
By considering the choice $v = p(t)/|p(t)|$ if $p(t) \neq 0$ or $v = 0$ otherwise in (4.7), we deduce that

$$|p(t)| \leq k_3 + r(t) \quad \text{a.e.}$$

Now choose any $s \in [\bar{t}, t_1]$ such that (4.9) is valid. Then for any $t \in [t_1, t']$ we have, by (4.6),

$$p(t) \leq k_3 + r(t) = k_3 + r(s) + r(t) - r(s) \leq k_2 + k_3 + \eta^*(t; k') - \eta^*(s, k') \leq k_2 + k_3 + K,$$

where $K$ is the constant in hypothesis (BV). Combining this relation with (4.8) and noting that $p(.)$ is continuous, we conclude that the values of $p(.)$ are uniformly bounded on all of $[\bar{t}, t']$, and the bound does not depend on $t'$. But, as we have earlier observed, the existence of such a bound implies $\dot{x}(.)$ is essentially bounded on $[\bar{t}, t']$.

We have shown that $\bar{x}(.)$ is Lipschitz continuous. To complete the proof we have merely to recall that, under (HE) and (HR), Lipschitz continuous minimizers satisfy the asserted necessary conditions.

5 Application 2: Non-Degeneracy of the State Constrained Hamiltonian Inclusion.

Consider the optimal control problem

\[
\begin{cases}
&\text{Minimize } g(x(T)) \\
&\text{over absolutely continuous functions } x(.) : [S, T] \to \mathbb{R}^n \text{ s.t.} \\
&P_1 \quad \hat{x}(t) \in F(t, x(t)) \text{ a.e.,} \\
&\quad h(x(t)) \leq 0 \quad \text{for all } t \in [S, T] \\
&\quad x(S) = x_0, \\
\end{cases}
\]

in which $x_0$ is a given $\mathbb{R}^n$ vector. To simplify the subsequent analysis, we assume:

\[(H3)' \quad h(.) \text{ is a continuously differentiable function satisfying } \nabla h(x_0) \neq 0.\]

$(P_1)$ will be recognized as a special case of $(P)$ in which $C = \{x_0\} \times \mathbb{R}^n$ (‘fixed initial state’). Let $\bar{x}(.)$ be an $L^\infty$-local minimizer for $(P_1)$. The state constrained Hamiltonian inclusion condition tells us: under unrestrictive hypotheses (details of which do not concern us here), there exist $p(.) \in W^{1,1}([S, T]; \mathbb{R}^n)$, a function $\mu(.) \in NBV^+[S, T]$ and $\lambda \geq 0$ such that

(i) $\langle p(.), \lambda, \mu(.) \rangle \neq (0, 0, 0),$

(ii) $(-\dot{p}(t), \dot{x}(t)) \in \tilde{\partial}_x p H(t, \bar{x}(t), q(t)) \text{ a.e. },$

(iii) $-q(1) \in \lambda \partial g(\bar{x}(T))$

and

(iv) $\text{supp } \{d\mu\} \subset \{t \mid h(t, \bar{x}(t)) = 0\}$
where
\[ q(t) = \begin{cases} 
  p(t) + \int_{[S,T]} \nabla h(x(s)) \mu(ds) & \text{if } t \in [S,T) \\
  p(t) + \int_{[S,T]} \nabla h(x(s)) \mu(ds) & \text{if } t = T.
\end{cases} \]

These conditions are deficient when
\[ h(x_0) = 0 \quad \text{‘initial state in the boundary’.} \quad (5.1) \]

Indeed it is easy to show that, in this case, any feasible \( F \)-trajectory \( \bar{x}(\cdot) \) satisfies conditions (i)-(iii) above, when we choose multipliers:
\[ p(\cdot) \equiv -\nabla h(\bar{x}(S)), \quad \mu(t) = \delta(t) \quad \text{and} \quad \lambda = 0, \quad (5.2) \]

and so the standard set of conditions (i)-(iii) convey no useful information about minimizers whatsoever.

As the proof of the following proposition shows, the additional information about the Hamiltonian in Thm. 3.1, coupled with an inward pointing condition at the left endpoint, provides an extra condition:
\[ \lambda + \int_{[S,T]} d\mu(s) \neq 0 \]

This condition excludes the ‘trivial’ set of multipliers \((5.2)\), in which \( \lambda = 0 \) and \( \mu(\cdot) \) comprises merely an atom at \{\( S \} \), and therefore strengthens the standard set of conditions (i)-(iii). Write
\[ H(t, x, p) = \sup \{ p \cdot v | v \in F(t, x) \}. \]

**Corollary 5.1.** Let \( \bar{x}(\cdot) \) be an \( L^\infty \)-local minimizer for \((P_1)\). Assume that hypotheses \((H1), (H2) \) (for \( L(\cdot, \cdot, \cdot) \equiv 0 \) ) and \((H3')\) are satisfied. Assume also that

\((BV)\): \( t \to F(t, \cdot) \) has bounded variation along \( \bar{x}(\cdot) \)

and

\((I)\): There exists \( v \in \lim \inf_{s \downarrow S} F(s, x_0) \) such that
\[ \nabla h(x_0) \cdot v < 0. \]

Then there exist \( p(\cdot) \in W^{1,1}([S, T]: \mathbb{R}^n) \), a function \( \mu(\cdot) \in NBV^+[S, T] \) and \( \lambda \geq 0 \) such that

(i) \( \lambda + \int_{[S,T]} \mu(ds) \neq 0 \),

(ii) \( (-\dot{p}(t), \dot{\bar{x}}(t)) \in \tilde{\partial}_{x,p} H(t, \bar{x}(t), q(t)) \) a.e. ,

(iii) \( (q(S), -q(T)) \in \lambda \partial g(\bar{x}(S), \bar{x}(T)) + N_{\tilde{C}}(\bar{x}(S), \bar{x}(T)), \)

where
\[ q(t) = \begin{cases} 
  p(t) + \int_{[S,T]} \nabla h(x(s)) \mu(ds) & \text{if } t \in [S,T) \\
  p(t) + \int_{[S,T]} \nabla h(x(s)) \mu(ds) & \text{if } t = T.
\end{cases} \]
Proof. From Thm. 3.1 we know that there exist \( p(.) \in W^{1,1}([S,T];\mathbb{R}^n) \), a function \( \mu(.) \in NBV^+[S,T] \) and \( \lambda \geq 0 \) such that (ii) and (iii) are satisfied, and 
\[
| |p(.)| |_{L^\infty} + \lambda + \int_{[S,T]} d\mu(s) \neq 0.
\]

We must check also condition (i). Suppose this condition is not satisfied. Let \( \tilde{q}(.) \) be the modification to \( q(.) \), in which \( q(S) \) is replaced by its left limit \( q(S^+) \). Then \( \tilde{q}(.) \) is an absolutely continuous function satisfying
\[
(-\tilde{q}(t), \dot{x}(t)) \in \partial_{x,p}H(t, \tilde{x}(t), \tilde{q}(t)) \quad \text{a.e.}
\]
and \( \tilde{q}(T) = 0 \). It can be deduced, with the help of Gronwall’s inequality, that \( \tilde{q}(.) \equiv 0 \). So \( q(t) = \tilde{q}(t) = 0 \) for \( t \in (S,T] \). Then
\[
H(t, \tilde{x}(t), q(t)) = 0 \quad \text{for all } t \in (S,T].
\]

Now let us examine the implications of the ‘extra’ information about \( \tilde{x}(.) \) supplied by Thm. 3.1: there exists a normalized function of bounded variation \( r(.) : [S,T] \rightarrow \mathbb{R} \), continuous at its endpoints, such that
\[
r(t) = H(t, \tilde{x}(t), q(t)) = 0 \quad \text{a.e } t \in (S,T] \quad \text{and } r(S) = H(S^+, \tilde{x}(S), p(S)).
\]
From the first condition and the continuity of \( r(.) \) at \( S \), we conclude that \( r(S) = 0 \). This implies that
\[
\sup_{v \in F(S^+, x_0)} p(S) \cdot v = 0. \quad (5.3)
\]
But \( p(S) = \tilde{q}(S^+) - \nabla h(x_0)\mu\{\{S\}\} = 0 - \nabla h(x_0)\mu\{\{S\}\} \). There are now two possibilities. It \( \mu(.) \equiv 0 \) then \( p(.) = \tilde{q}(.) \equiv 0 \). This contradicts the non-triviality condition \( | |p(.)| |_{L^\infty} + \lambda + \int_{[S,T]} d\mu(s) \neq 0 \). On the other hand, if \( \mu\{\{S\}\} \neq \gamma > 0 \) then
\[
H(S^+, x_0, p(S)) = \sup_{v \in F(S^+, x_0)} p(S) \cdot v = - \inf_{v \in F(S^+, x_0)} \gamma \nabla h(x_0) \cdot v > 0,
\]
by hypothesis (I). This contradicts (5.3). This concludes the proof.

Comments.

(a): The idea of using regularity of the Hamiltonian to justify the exclusion of trivial multipliers in state constraint optimal control is due to Arutyunov and Aseev. They assume that the data is Lipschitz continuous with respect to time. The corollary improves on this earlier work, by excluding the trivial multiplier set when the data is merely of bounded variation with respect to time.

(b): The corollary excludes just one type of non-degeneracy. The condition (i) still permits \( \lambda = 0 \), a case in which the necessary conditions make no reference to the cost function and merely convey information about the constraints. The hypotheses can be strengthened to ensure also normality, i.e. we can choose \( \lambda \neq 0 \), in cases not covered in the earlier ‘non-degeneracy’ literature.
6 Preliminary Analysis: Discrete Approximations

A key step in the proof the \( H[.] \) has bounded variation when \( F(., x) \) has bounded variation will be to derive necessary conditions for a perturbation of problem \((P)\), resulting from the discrete approximation of the multifunction \( F(., x) \) (and the addition of penalty terms to the cost). The perturbed problem \((P)'\) has the form of a multistage optimal control problem, with end-times taken to be the grid points of a partition of \([S, T]\):

\[
\begin{align*}
(P') \quad \begin{cases} 
\text{Minimize } & g(x(S), x(T)) + \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} L_i(x(t), \dot{x}(t))dt + \int_{S}^{T} e(t, x(t))dt \\
& \text{over absolutely continuous functions } x(.) : [S, T] \rightarrow \mathbb{R}^n \text{ s.t.} \\
& \dot{x}(t) \in F_i(x(t)) \text{ a.e. } t \in [t_i, t_{i+1}), i = 0, \ldots, N-1 \\
& (x(S), x(T)) \in C,
\end{cases}
\end{align*}
\]

for which the data is as follows: a partition \(\{t_0 = S, t_1, \ldots, t_{N-1}, t_N = T\}\) of \([S, T]\), multifunctions and functions \(F_i(.) : \mathbb{R}^n \rightarrow \mathbb{R}^n\) and \(L_i : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}\), \(i = 0, \ldots, N-1\), functions \(e(.) : [S, T] \times \mathbb{R}^n \rightarrow \mathbb{R}\) and \(g(.) : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}\), and a set \(C \subset \mathbb{R}^n \times \mathbb{R}^n\). The special structure of the cost integrand reflects the requirements of the analysis to follow.

Problem \((P)'\) will be recognised as a special case of the problem \((P)\) of the introduction, when the following identifications are made for \(F(., .)\) and \(L(., ., .)\):

\[
F(t, x) = \sum_{i=0}^{N-1} F_i(x) \chi_{[t_i, t_{i+1})}(t) \text{ a.e.,}
\]

\[
L(t, x, v) = \sum_{i=0}^{N-1} L_i(x, v) \chi_{[t_i, t_{i+1})}(t) + e(t, x).
\]

Define the \(i\)'th stage hamiltonian \(H^{i}_{\lambda}(., ., .)\) (parameterized by the cost multiplier \(\lambda\)) to be

\[
H^{i}_{\lambda}(t, x, p) := \max_{v \in F(t, x)} \{p \cdot v - \lambda L(t, x, v)\}
\]

for \((x, p) \in \mathbb{R}^n \times \mathbb{R}^n\) and \(t \in [t_i, t_{i+1}), i = 0, \ldots, N-1\).

**Proposition 6.1.** Let \(\bar{x}(.)\) be an \(L^\infty\)-local minimizer for \((P)'\). Assume, for some \(\delta > 0\),

\(\text{(HM1): } F_i(.) \text{ takes values closed, non-empty sets, } i = 0, \ldots, N - 1 \text{ and } L(., .) \text{ is continuous. } g(., .) \text{ is Lipschitz continuous on } (\bar{x}(S), \bar{x}(T)) + \bar{\delta}(\mathbb{B} \times \mathbb{B}).\)

\(\text{(HM2): There exist } k > 0 \text{ and } c > 0, \text{ such that, for each } i \in \{0, \ldots, N - 1\}, L_i(., .) \text{ is bounded on bounded sets, and }\)

\[
F_i(x) \subset F_i(x') + k(|x - x'|)B \quad \text{and} \quad F_i(x) \in cB
\]

\[
|L_i(x, v) - L_i(x', v)| \leq k|x - x'|
\]

18
for all \( x, x' \in \bar{x}(t) + \delta B, v \in F(t, x) \), a.e. \( t \in [S, T] \).

**HM3:** \( e(\cdot, \cdot) \) is Lipschitz continuous on bounded subsets

Then there exist \( p(\cdot) \in W^{1,1}([S, T]; \mathbb{R}^n) \) and \( \lambda \geq 0 \) such that

(i) \( (p(\cdot), \lambda) \neq (0, 0) \),

(ii) \( (-\dot{p}(t), \dot{x}(t)) \in \co \partial x, p H^\lambda_1(\bar{x}(t), p(t)) - \lambda \co \partial x e(t, \bar{x}(t)) \times \{0\} \)

a.e. \( t \in [t_i, t_{i+1}], \ i = 0, \ldots, N - 1 \), where \( \partial x e(t, x) := \limsup_{s \to t} \co \partial x e(s, x) \),

(iii) \( (p(S), -p(T)) \in \lambda \partial g(\bar{x}(S), \bar{x}(T)) + N_C(\bar{x}(S), \bar{x}(T)) \),

Furthermore, there exists a piecewise Lipschitz continuous function \( r(\cdot) : [S, T] \to \mathbb{R} \), with discontinuities confined to the set \( \{t_1, \ldots, t_{N-1}\} \) satisfying

(iv) \( \dot{r}(t) \in \lambda \co \partial x e(t, \bar{x}(t)) \) a.e.

(v) \( r(t) = H^\lambda_1(t, \bar{x}(t), p(t)) \) a.e. \( t \in [t_{i-1}, t_i], \ i = 1, \ldots, N \).

**Proof.** The proof is based on a well-known idea for deriving conditions on \( H[\cdot] \), when the data is Lipschitz continuous in time. It is to observe that the given \( L^\infty \)-local minimizer \( \bar{x}(\cdot) \) remains an \( L^\infty \)-local minimizer after the domain of the optimization problem is enlarged to include the effects of an arbitrary change of independent variable, and then to apply standard necessary conditions to the modified optimization problem. We thereby obtain, not just the usual necessary conditions for the \( L^\infty \)-local minimizer, but the desired additional information about \( H[\cdot] \). For problem \((P)'\), the data is not Lipschitz continuous in \( t \). But it is piecewise continuous, and we can use the idea to establish piecewise Lipschitz continuity of \( H[\cdot] \). Take an \( L^\infty \) minimizer \( \bar{x}(\cdot) \) for \((P'')\) which is minimizint with respect to feasible \( F \)-trajectories that satisfy:

\[
\|x(\cdot) - \bar{x}(\cdot)\|_{L^\infty} \leq \bar{\epsilon}
\]

for some \( \bar{\epsilon} > 0 \). Consider the function:

\[
\{(\bar{z}_i(\cdot), \bar{\tau}_i(\cdot), \bar{x}_i(\cdot))\}_{i=0}^{N-1} : [S, T] \to (\mathbb{R} \times \mathbb{R} \times \mathbb{R}^n)^N
\]

in which, for \( i = 0, \ldots, N - 1 \),

\[
(\bar{z}_i(s), \bar{\tau}_i(s), \bar{x}_i(s)) = \begin{cases} 
(\int_{t_i}^s L(s, \bar{x}(s'), \dot{x}(s'))ds', s, \bar{x}(s)) & \text{for } s \in [t_i, t_{i+1}] \\
(0, t_i, \bar{x}(t_i)) & \text{for } s \in [S, t_i] \\
(\int_{t_i}^{t_i+1} L(s', \bar{x}(s'), \dot{x}(s'))ds', t_{i+1}, \bar{x}(t_{i+1})) & \text{for } s \in (t_i, T].
\end{cases}
\]

We claim that, for \( \epsilon' > 0 \) sufficiently small, (6.1) is an \( L^\infty \)-local minimizer for \((P'')\):
In view of the constraints imposed in problem \((P)\), now follow from an application of known necessary conditions to \((P)\), exercise to show that \(x_i\) has for \((P)\):

\[
\begin{aligned}
\{z_i(\cdot), \tau_i(\cdot), x_i(\cdot)\}_{i=0}^{N-1} : [S, T] \rightarrow (\mathbb{R} \times \mathbb{R} \times \mathbb{R}^n)^N,
\end{aligned}
\]

satisfying, for a.e. \(t \in [t_i, t_{i+1}]\) and \(i = 0, \ldots, (N - 1)\),

\[
\begin{aligned}
& (z_i(s), \tau_i(s), x_i(s)) \
& \in \{(1 + w)L_i(x_i(s), v), (1 + w)(1 + w)v \mid w \in [1 - \epsilon', 1 + \epsilon'], v \in F_i(s, x_i(s)) \} \\
& \quad \text{if } s \in [t_i, t_{i+1}] \\
& \quad \text{if } s \in [S, T \setminus [t_i, t_{i+1}]] \\
& (x_0(S), x_{N-1}(T)) \in C, \\
& (z_i(S), \tau_i(S), \tau_i(T)) = (0, t_i, t_{i+1}) \text{ for } i = 0, \ldots, N - 1 \\
& x_i(T) = x_{i+1}(S) \text{ for } i = 0, \ldots, N - 2.
\end{aligned}
\]

To see this, fix \(\alpha > 0\) and \(\epsilon' \in (0, 1)\), and take any \(F\)-trajectory for \((P')\),

\[
\begin{aligned}
\{(z_i(\cdot), \tau_i(\cdot), x_i(\cdot))\}_{i=0}^{N-1},
\end{aligned}
\]

satisfying

\[
\begin{aligned}
||\{(z_i(\cdot), \tau_i(\cdot), x_i(\cdot)) - \{z_i(s), \tau_i(s), x_i(s)\}\}|L_\infty\leq \alpha.
\end{aligned}
\]

Then, in view of the dynamic constraint in \((P')\), there exist measurable functions \(w(\cdot) : [S, T] \rightarrow [1 - \epsilon', 1 + \epsilon']\), and \(v(\cdot) : [S, T] \rightarrow \mathbb{R}^n\) such that

\[
\begin{aligned}
& \{\{(1 + w)L(s, x_i(s), v), (1 + w)(1 + w)v \mid w \in [1 - \epsilon', 1 + \epsilon'], v \in F(s, x_i(s)) \} \\
& \quad \text{if } s \in [t_i, t_{i+1}] \\
& \quad \text{if } s \in [S, T \setminus [t_i, t_{i+1}]]
\end{aligned}
\]

for a.e. \(s \in [t_i, t_{i+1}]\) and \(i = 0, \ldots, (N - 1)\). Now consider the function \(\phi(\cdot) : [S, T] \rightarrow \mathbb{R}\)

\[
\phi(s) = S + \int_{[S, s]} \left\{ \sum_{i=0}^{N-1} (1 + w(s'))\chi_{[t_i, t_{i+1}]}(s') \right\} ds'.
\]

In view of the constraints imposed in problem \((P')\), \(\phi(\cdot)\) is a Lipschitz continuous, strictly increasing function with a Lipschitz continuous inverse, such that \(\phi(t_i) = t_i\)

for \(i = 0, \ldots, N\). Furthermore

\[
y(s) = \sum_{i=0}^{N-1} x_i(s)\chi_{[t_i, t_{i+1}]}(s)
\]

is an absolutely continuous function. It is a straightforward ‘change of independent variable’ exercise to show that \(x(\cdot) : [S, T] \rightarrow \mathbb{R}^n\) defined by

\[
x(t) := y(\phi^{-1}(t))
\]

is a feasible \(F\)-trajectory for \((P)\) and has the same cost as \(\{(z_i(\cdot), \tau_i(\cdot), x_i(\cdot))\}_{i=0}^{N-1}\) has for \((P')\). Also, \([6.11]\) has the same cost for \((P')\). by choosing \(\epsilon\) and \(\alpha\) sufficiently small, we can arrange that, however the choice of \(\{(z_i(\cdot), \tau_i(\cdot), x_i(\cdot))\}\), we have

\[
||x(\cdot) - \tilde{x}(\cdot)||_L_\infty \leq \epsilon.\]

The claim is confirmed. The assertions of proposition now follow from an application of known necessary conditions to \((P')\) \([13, \text{ThmXX}]\).

We shall also require certain convergence properties, as the mesh size tends to zero, of interpolants of suitably bounded points on a grid, summarized in the lemma:
Lemma 6.2. Take a compact set $A \subset \mathbb{R}^k$, a continuous function $\bar{x}(\cdot) : [S, T] \to \mathbb{R}^n$ and a multifunction $F(\cdot, \cdot, \cdot) : [S, T] \times \mathbb{R}^n \times A \to \mathbb{R}^n$ which has bounded variation along $\bar{x}(\cdot)$ uniformly over $A$. Denote by $\eta(\cdot)$ its cumulative variation function, and by $\eta^\delta(\cdot)$ the related $(\delta, \epsilon)$-perturbed functions. Assume that hypotheses $(C1)$ and $(C2)$ of Prop. 2.1 are satisfied. Take a sequence of families of numbers $\{d_j^i\}^N_{j=1}$ and a sequence of numbers $\{m_0^i\}$. For each $i$, let $\mathcal{T}_i = \{t_0^i, t_1^i, \ldots, t_{N_i}^i, t_{N_i}^i = T\}$ be a partition of $[S, T]$ and define the piecewise constant interpolation function

$$m_i(t) = m_0^i + \sum_{j=1}^{N_i-2} d_j^i \chi_{[t_j^i, t_{j+1}^i)}(t) + d_{N_i-1}^i \chi_{[t_{N_i-1}^i, t_{N_i}^i]}(t).$$

Assume that

(A1): $\text{diam}\{\mathcal{T}_i\} \to 0$ as $i \to \infty$.

(A2): $\{m_0^i\}$ is a bounded sequence.

(A3): There exist an integer valued function $(\epsilon, \delta) \to I(\epsilon, \delta)$ such that, for any $\epsilon > 0$ and $\delta > 0$,

$$|d_j^i| \leq \eta^\delta(\epsilon^i_\epsilon(t_j^i)) - \eta^\delta(\epsilon^i_{\epsilon-1}(t_j^i)) \quad \text{for all } j \in \{1, \ldots, N_i\}, \text{ and } i \geq I(\epsilon, \delta).$$

Then there exist a normalized function of bounded variation $m(\cdot) : [S, T] \to \mathbb{R}^n$ and a countable set $A \subset (S, T)$, such that, along some subsequence,

$$m_i(t) \to m(t) \quad \text{for all } t \in [S, T] \setminus A$$

and

$$|m(t) - m(s)| \leq \eta^*(t) - \eta^*(s) \quad \text{for all } [s, t] \subset [S, T],$$

in which $\eta^*(\cdot)$ is the normalized cumulative variation

$$\eta^*(t) := \begin{cases} \eta(t) & \text{if } t = S \text{ or } T \\ \eta(t^+) & \text{if } t \in (S, T) \end{cases}$$

where $\eta(t^+) := \lim_{s \to t^+} \eta(s)$.

A proof of the lemma appears in the Appendix.

7 Proof of Theorem 3.1

Consider first the case $L(\cdot, \cdot, \cdot) \equiv 0$. Here, the Hamiltonian $H(\cdot, \cdot, \cdot)$, defined by (3.1), no longer depends on $\lambda$ and we write it simply $H(\cdot, \cdot, \cdot)$.

By reducing the size of $\bar{\delta} > 0$ in hypotheses (H1) – (H3) we can arrange that $\eta^\delta_F(T) < \infty$. We may choose $\bar{\epsilon} > 0$ such that $\eta^{\bar{\delta} + \bar{\epsilon}}_F(T) < \infty$. Since $\bar{x}(\cdot)$ is an $L^\infty$-local minimizer, we may arrange (again by reducing the size of $\bar{\delta} > 0$ if required) that $\bar{x}(\cdot)$ minimizes $g(x(S), x(T))$ over all feasible $F$-trajectories for (P) satisfying
\[ ||x(.) - \bar{x}(.)||_{L^\infty} \leq \delta. \]

We impose the following temporary hypothesis:

(C): \( t \to F(t, .) \) is right and left continuous at \( S \) and \( T \) respectively, in the following sense: for some \( \delta \in (0, \delta), \)

\[ \lim_{s \downarrow S} \sup_{x \in \bar{x}(S) + \delta B} d_H(F(S, x), F(s, x)) = 0, \quad \lim_{t \uparrow T} \sup_{x \in \bar{x}(T) + \delta B} d_H(F(T, x), F(t, x)) = 0. \]

Take a sequence of positive integers \( N_i \uparrow \infty \). Define \( \epsilon_i = |T - S|/N_i \). For each \( i \), let \( \{t^i_0 = S, t^i_1, \ldots, t^i_{N_i-1}, t^i_{N_i} = T\} \) be the uniform partition of \([S, T]\) into \( N_i \) subintervals. Define

\[ F_i(t, x) := \sum_{j=0}^{N_i-1} F(t^i_j, x) \chi_{[t^i_j, t^i_{j+1})}(t) + F(t^i_{N_i-1}, x) \chi_{[t^i_{N_i-1}, t^i_{N_i}]}(t). \]

In view of (H2),

\[ \int_S^T dF_i(t, \tilde{x}(t)) (\tilde{x}(t)) dt \leq \frac{T - S}{N_i} \times \left( \sum_{j=0}^{N_i-1} \eta_{F_i, \epsilon}(t^i_{j+1}) - \eta_{F_i, \epsilon}(t^i_j) \right) = \frac{T - S}{N_i} \times \left( \eta_{F_i, \epsilon}(T) - \eta_{F_i, \epsilon}(S) \right), \]

\[ \to 0 \quad \text{as} \quad i \to \infty. \]

It follows from Filippov’s Existence Theorem [] that there exists an absolutely continuous function \( z_i(.) \) such that \( \dot{z}_i(t) \in F_i(t, z_i(t)), \) a.e., and \( z_i(S) = \bar{x}(S), \) and a sequence \( \alpha_i \downarrow 0 \) such that

\[ ||z_i(.) - \bar{x}(.)||_{L^\infty} \leq \alpha_i \]

for all \( i \) sufficiently large. For each \( i \) we have \( h(z_i(t)) \leq k_h \alpha_i \), where \( k_h \) is the constant of (H3) and \( (z_i(S), z_i(T)) \in \tilde{C} + \sqrt{2} \times \alpha_i \mathbb{B}. \) Notice that

\[ \tilde{C} + \sqrt{2} \times \alpha_i \mathbb{B} \subset \{(x_0, x_1) \mid h(x_0) \lor h(x_1) \leq 2 \times k_h \alpha_i \}. \]

Take a sequence \( \beta_i \downarrow 0 \) such that \( \beta_i > 2k_h \alpha_i \) for each \( i \). Then

\[ \tilde{C} + \sqrt{2} \times \alpha_i \mathbb{B} \subset \{(x_0, x_1) \mid h(x_0) \lor h(x_1) < \beta_i \}. \]

Now take any sequence of numbers \( K_i \uparrow \infty \) and, for each \( i \), consider the optimization problem

\[ (P_i) \begin{cases} \text{Minimize } g(x(S), x(T)) + \int_S^T \left( |x(t) - \bar{x}(t)|^2 + K_i \left( h(x(t)) - \beta_i \right)^+ \right) dt \\ \text{such that} \\ \dot{x}(t) \in F_i(t, x(t)) \text{ a.e.,} \\ (x(S), x(T)) \in \tilde{C} + \sqrt{2} \times \alpha_i \mathbb{B}, \\ |x(t) - \bar{x}(t)| \leq \delta/2 \quad \text{for all } t \in [S, T]. \end{cases} \]
For each $i$, $(P_i)$ has a minimizer $x_i(\cdot)$, since the data for this problem satisfy the standard conditions for existence of minimizers. (The assumed convexity of the velocity sets $F(t, x)$ is crucial here.) Notice that the $\alpha_i$'s have been chosen to ensure existence of feasible $F$-trajectories for this problem. Since the $x_i(\cdot)$'s are uniformly bounded and the $\dot{x}_i(\cdot)$'s are uniformly integrably bounded we know that, along some subsequence (we do not relabel),

$$||x_i(\cdot) - x'(\cdot)||_{L^\infty} \to 0, \quad (7.1)$$

for some absolutely continuous function $x'(\cdot)$ satisfying $||x'(\cdot) - \bar{x}(\cdot)||_{L^\infty} \leq \delta/2$. Appealing once again to Filippov’s Existence Theorem we can show that, for each $i$ sufficiently large, there exists an $F$-trajectory $y_i(\cdot)$ such that $||x_i(\cdot) - y_i(\cdot)||_{L^\infty} \to 0$. It follows from (7.1) that

$$||y_i(\cdot) - x'(\cdot)||_{L^\infty} \to 0.$$ But then, by standard closure properties of solutions of convex valued differential inclusions, $x'(\cdot)$ is an $F$-trajectory. Notice that, since $(x_i(S), x_i(T)) \in \tilde{C} + \sqrt{2} \times \alpha_i\mathbb{B}$ for each $i$,

$$(x'(S), x'(T)) \in \tilde{C}. \quad (7.2)$$

Observe next that the $z_i(\cdot)$'s satisfy the conditions

$$(z_i(S), z_i(T)) \in \tilde{C} + \sqrt{2} \times \alpha_i\mathbb{B}, \max_{t \in [S, T]} (h(z_i(t)) - \beta_i) < 0 \text{ and } ||z_i(\cdot) - \bar{x}(\cdot)||_{L^\infty} \leq \delta/2,$$

for $i$ sufficiently large. It follows that $z_i(\cdot)$ is feasible for $(P_i)$ and cannot have cost less than that of $x_i(\cdot)$. But then

$$g(x_i(S), x_i(T)) + \int_S^T |x_i(t) - \bar{x}(t)|^2 dt + K_i \int_S^T (h(x_i(t)) - \beta_i)^+ dt \leq g(z_i(S), z_i(T)) + \int_S^T |z_i(t) - \tilde{x}(t)|^2 dt + 0.$$ Since $||z_i(\cdot) - \bar{x}(\cdot)||_{L^\infty} \to 0$ and $||x_i(\cdot) - x'(\cdot)||_{L^\infty} \to 0$, we have

$$g(x'(S), x'(T)) + \int_S^T |x'(t) - \tilde{x}(t)|^2 dt + \limsup_{i \to \infty} K_i \int_S^T (h(x_i(t)) - \beta_i)^+ dt \leq g(\tilde{x}(S), \tilde{x}(T)). \quad (7.3)$$

It follows from $K_i \uparrow \infty$ that $\int_S^T (h(x_i(t)) - \beta_i)^+ dt \to 0$.

We deduce from the continuity of $t \to h(x(t))$ that

$$h(x'(t)) \leq 0 \text{ for all } t \in [S, T].$$

But then, by (7.2), $x'(\cdot)$ is a feasible $F$-trajectory for the original problem $(P)$, which satisfies $||x'(\cdot) - \bar{x}(\cdot)||_{L^\infty} \leq \delta/2$. In consequence then of the local optimality of $\tilde{x}(\cdot)$,

$$g(x'(S), x'(T)) \geq g(\tilde{x}(S), \tilde{x}(T)).$$
We deduce from this relation and (7.3) that \( x'(.) = \bar{x}(.) \). Then, by (7.4),
\[
||x_i(.) - \bar{x}(.)||_{L^\infty} \to 0.
\]
and
\[
K_i \int_S^T (h(x_i(t)) - \beta_i)^+ dt \to 0.
\]
It follows from Egorov’s Theorem that, after subtracting a subsequence,
\[
K_i (h(x_i(t)) - \beta_i)^+ \to 0 \quad \text{a.e.} \tag{7.5}
\]
In view of (7.4), \( x_i(.) \) is a \( L^\infty \)-local minimizer for a modified version of \( (P_i) \), resulting from removal of the constraint \( ||x(.) - \bar{x}(.)||_{L^\infty} \leq \bar{\delta}/2' \). The hypotheses are satisfied for the application of the ‘multistage’ necessary conditions Prop. 6.1 of the preceding section. Write \( q \) for the costate variable and \( \lambda \) for the cost multiplier. The Hamiltonian for \( (P_i) \) is
\[
H_i(t, x, q) = \lambda |x - \bar{x}(t)|^2 - \lambda K_i (h(x) - \beta_i)^+,
\]
in which
\[
H_i(t, x, q) = \max \{ q \cdot e \mid e \in F_i(t, x) \}. \tag{7.6}
\]
The necessary conditions assert the existence, for each \( i \), of \( q_i(.) \in W^{1,1}([S, T]; \mathbb{R}^n) \) and a piecewise absolutely continuous function \( r_i(.) : [S, T] \to \mathbb{R} \), with possible jumps at \( t_{i,1}, \ldots, t_{i,N_i-1} \) and right continuous on \( (S, T) \), such that
\[
(-\dot{q}_i(t), \dot{x}_i(t)) \in co \partial_x H_i(t, x_i(t), q_i(t))
\]
\[
\quad -2\lambda_i(x_i(t) - \bar{x}(t)) - 2\gamma_i(t)K_i \nu_i(t) \quad \text{a.e.,}
\tag{7.7}
\]
in which \( \gamma_i(.) : [S, T] \to \mathbb{R}^n \) and \( \nu_i(.) : [S, T] \to [0, 1] \) are measurable functions such that
\[
\gamma_i(t) \in co \partial_x^2 h(x_i(t)) \tag{7.8}
\]
for almost all \( t \in \{ s \in [S, T] : \nu_i(s) > 0 \} \). To derive these relations, we have used the subdifferential calculus rule
\[
\partial [h(x) - \beta, 0]^+ \subset \left\{ \nu \partial h(x) \mid \nu \in [0, 1] \right\} \quad \text{for } h(x) - \beta \geq 0
\]
otherwise.

Also:
\[
\dot{r}_i(t) = 2\lambda_i(x_i(t) - \bar{x}(t)) \cdot \dot{x}(t) \quad \text{a.e.} \tag{7.9}
\]
and
\[
- r_i(t) + H_i(t, x_i(t), q_i(t)) - \lambda_i|x_i(t) - \bar{x}(t)|^2 - \lambda_i K_i [h(x_i(t)) - \beta_i]^+ = 0 \quad \text{a.e.} \tag{7.10}
\]
Furthermore
\[
q_i(t) \cdot \dot{x}_i(t) = \max_{e \in F_i(t, x_i(t))} q_i(t) \cdot e \quad \text{a.e.} \tag{7.11}
\]
and
\[
(q_i(S), -q_i(T)) \in \lambda_i \partial g(x_i(S), x_i(T)) + N_{\tilde{C}+\sqrt{2}\alpha_i E}(x_i(S), x_i(T)) \tag{7.12}
\]
Now define  
\[ \mu_i(dt) := \lambda_i K_i \nu_i(t) dt \]
and  
\[ p_i(t) := q_i(t) - \int_{[S,T]} \gamma_i(s) \mu_i(ds) \]
it follows from the last two relations that \((q_i(.), \lambda_i) \neq (0,0)\). We can arrange then, by scaling the multipliers, that  
\[ ||p_i(.)||_{L^\infty} + \lambda_i + ||\mu_i(.)||_{TV} = 1. \quad (7.12) \]
We note from (7.8) that  
\[ r_i(.), \quad \text{by scaling the multipliers}, \]
and  
\[ \text{by scaling the multipliers, that} \]
\[ ||p_i(.)||_{L^\infty} + \lambda_i + ||\mu_i(.)||_{TV} = 1. \quad (7.12) \]
We note from (7.8) that \( r_i(.) \) has the representation  
\[ r_i(t) = \tilde{r}_i(t) - \int_S^t (2\lambda_i(x_i(s) - \bar{x}(s)) \cdot \dot{x}(s)) ds, \quad (7.13) \]
where \( \tilde{r}_i(.) \) is the piecewise constant function with distributional derivative expressed in terms of the jumps  
\[ \Delta_j^i = r_i(t_j^+) - r_i(t_j^-) \quad j = 1, \ldots, N - 1 \]
as  
\[ \dot{\tilde{r}}_i(t) = \sum_{j=1}^{N-1} \Delta_j^i \delta(t - t_j). \quad (7.14) \]
Here, \( \delta(.) \) is the Dirac delta function. We see from (7.9) that the jumps in \( \tilde{r}_i(.) \) are  
\[ \Delta_j^i = H_i(t_j^+, x_i(t_j^+), q_i(t_j^+)) - H_i(t_j^-, x_i(t_j^-), q_i(t_j^-)), \]
which, in view of (H3), can be estimated by  
\[ ||\Delta_j^i|| \leq ||q_i(.)||_{TV} \times \left[ \eta_{\delta_i}^i(t_j^+ - t_j^-) \right]. \quad (7.15) \]
Since \( \lambda_i K_i[h(x_i(.)) - \beta_i] \to 0 \) in \( L^1 \) and \( t \to H_i(t, x_i(t), q_i(t)) - \lambda_i|x_i(t) - \bar{x}(t)|^2, \)
\( i = 1, 2, \ldots, \) is a uniformly bounded sequence of functions, we can conclude from (7.8) that \( \{r_i(.)\} \) is bounded with respect to the \( L^1 \) norm. Note however that, by (7.14) and (7.15), \( \tilde{r}_i(.) \) has total variation bounded by  
\[ ||q_i(.)||_{L^\infty} \times \left[ \eta_{\delta_i}^i(T) - \eta_{\delta_i}^i(S) \right] \]
A simple contradiction argument based on (7.13) permits us to conclude that \( r_i(S)(= \tilde{r}_i(S)) \) is a bounded sequence.

We now apply Lemma 6.2 when we identify \( m_i(.) \) with \( \tilde{r}_i(.) \), \( d_j^i \) with \( r(t_j^{i+}) - r(t_j^{i-}) \)
and \( \eta_{\delta_i}^i(.) \) with \( K' \eta_{\delta_i}^i(.) \), in which \( K' \) is any number such that  
\[ K' > \lim_{i \to \infty} \sup ||q_i(.)||_{L^\infty}. \]
The lemma tells us that there exists a normalized function of bounded variation  
\( r(.) : [S, T] \to \mathbb{R} \) and a countable subset \( \mathcal{A} \subset (S, T) \) such that  
\[ \tilde{r}_i(t) \to r(t) \text{ for all } t \in [S, T] \setminus \mathcal{A}, \]

25
and

$$|r(t) - r(s)| \leq K' \times (\eta^p_\varepsilon(t) - \eta^p_\varepsilon(s))$$  \hspace{1cm} (7.16)$$

for all $[s, t] \subset [S, T]$.

We deduce from (7.9), the facts that $h(x_i(S)) < \beta_i$ and $h(x_i(T)) < \beta_i$, and the interim 'continuity' hypothesis (C) that, for some $p_i \downarrow 0$,

$$r_i(S) = H(S, x_i(S), p_i(S)) + \lambda_i|x_i(S) - \bar{x}(S)|^2$$
$$r_i(T) \in H(T, x_i(T), q_i(T)) + \lambda_i|x_i(T) - \bar{x}(T)|^2 + \rho_i \times ||q_i||_{L\infty}B.$$  \hspace{1cm} (7.17)$$

(We have used here the fact that $F$ is uniformly bounded. It follows that, for a subsequence, $p_i \downarrow 0$, $\hat{\rho}_i \rightarrow \hat{\rho}$, $\hat{\rho}_i$ weakly in $L^1$, $\mu_i(\cdot) \rightarrow \mu(\cdot)$ weakly* $\gamma_i d\mu_i \rightarrow \gamma d\mu$ weakly* and $q_i(\cdot) \rightarrow q(\cdot)$ weakly*,

for some Lipschitz continuous function $p(\cdot)$, $\lambda \geq 0$, some function of bounded variation $q(\cdot)$, some measure $\mu(\cdot)$, and some Borel measurable function $\gamma(\cdot)$. Define

$$q(t) := p(t) + \int_{(S,t)} \gamma(s)\mu(ds)$$

A straightforward extension of the convergence analysis in [18] permits us to pass to the limit in the relations (7.6), (7.7), (7.11) and (7.12) and thereby deduce

$$(p(S), -q(T)) \in \lambda \partial_\gamma g(\bar{x}(S), \bar{x}(T)) + N_{\gamma}(\bar{x}(S), \bar{x}(T)),$$  \hspace{1cm} (7.20)$$

$m(t) = \co \partial_\gamma h(t, \bar{x}(t))$ $\mu$-a.e. $t \in [S, T]$,

$r(S) = H(S, \bar{x}(S), p(S))$ and $r(T) = H(T, \bar{x}(T), q(T)).$  \hspace{1cm} (7.22)$$

(Note that, for any $t \in [S, T]$, $H_i(t, \ldots)$ and $(H(t, \ldots)$ may fail to coincide. Nonetheless, for any index value $i$ and $t \in [S, T]$, $H_i(t, \ldots) = H(s, \ldots)$ for some $s$ such that $|t - s| \leq \delta_i$. So the partial subdifferential employed to capture limiting behavior for a particular time $t$, must take account of partial subgradients of $H(\ldots)$ at neighbouring times $s$. This is why the 'hybrid' partial subdifferential $\partial_\gamma H$ appears in (7.18) in place of the customary $\co \partial_\gamma H$. To derive the relation (7.18) we make use of the fact: at all points $t$ in a subset of $[S, T]$ of full measure and some $\epsilon' > 0$, $t \rightarrow F(t, x)$ is continuous, uniformly over $x \in \bar{x}(t) + \epsilon' B$. See Prop. 2.11.)

We deduce from (7.9), with the help of (7.5) that

$$r(t) = H(t, \bar{x}(t), q(t))$$ a.e.
Reviewing the preceding relations (7.16) and (7.24) - (??) and, we see that the proof of the theorem in the 'L(.,.,.) \equiv 0' case is almost complete. But there are some minor matters that require attention, relating to the function \( r(t) \). First, in the proof \( K \) is taken to be any number \( K' > K \) where

\[
K = \lim_{i \to \infty} \sup_i |q_i(\cdot)|_{L^\infty} = ||q(\cdot)||_{L^\infty}
\]

To justify replacing \( K' \) by \( K \) in relation (7.16) we take a sequence \( K_j \downarrow K \). For each \( j \), we obtain the above relations with multipliers indexed by \( j \). The desired necessary conditions, involving \( K \), are obtained by extracting subsequences and passage to the limit in these relations.

The other matters concern the imposition of the temporary hypothesis \((C)\) and also the fact that the theorem statement additionally asserts the continuity of \( r(\cdot) \) at the endpoints of the interval \([S, T]\). Suppose condition \((C)\) is not valid. Then, since \( t \to F(t, \cdot) \) is assumed to have bounded variation along \( \bar{x}(\cdot) \), \((C)\) is satisfied when the Hamiltonian inclusion \( \dot{x}(t) \in F(t, x(t)) \) is replaced by \( \dot{x}(t) \in \bar{F}(t, x(t)) \), given by (2.34). Notice that \( F(\cdot, \cdot) \) is obtained by changing \( t \to F(t, \cdot) \) only on a null-set, and so this procedure does not affect \( F \)-trajectories. \( \bar{x}(\cdot) \) remains an \( L^\infty \)-local minimizer.

The only respect in which this changes the preceding relations is to replace \( \eta^*(\cdot) \) in (7.16) by the normalized cumulative variation function \( \tilde{\eta}^*(\cdot) \) of \( t \to \bar{F}(t, \cdot) \) in relation (7.16). We may deduce from Prop. 2.2, however, that

\[
r(t) - r(s) \leq \tilde{\eta}^*(t) - \tilde{\eta}^*(s) = \eta^*(t) - \eta^*(s)
\]

for \([s, t] \subset (S, T)\). But we also know from Prop. 2.2 that \( \tilde{\eta}^*(\cdot) \) is continuous at the two endpoints of the interval \([S, T]\). So

\[
\lim_{t \uparrow S} |r(t) - r(S)| \leq \lim_{t \uparrow S} \tilde{\eta}^*_F(t) - \eta^*_F(S^+) = 0
\]

and

\[
\lim_{t \uparrow T} |r(T) - r(t)| \leq \tilde{\eta}^*_F(T^-) - \lim_{t \uparrow T} \eta^*_F(t) = 0 .
\]

We have shown that \( r(\cdot) \) has the desired continuity properties. This completes the proof of the special case of the theorem.

Now suppose that \( L(.,.,.) \) is non-zero. Then the assertions of the theorem may be deduced from those of the special case treated above by the well known state augmentation technique, based on the fact that \((\bar{x}(\cdot), \bar{z}(\cdot))\) is an \( L^\infty \)-local minimizer for the optimal control problem, with state dimension \( n + 1 \),

\[
(PA) \left\{ \begin{array}{l}
\text{Minimize } g(x(S), x(T)) + z(T) \\
\text{over absolutely continuous functions } (x(\cdot), z(\cdot)) : [S, T] \to \mathbb{R}^{n+1} \text{ s.t.}
\end{array} \right.
\]

\[
(\dot{x}(t), \dot{z}(t)) \in \bar{F}(t, x(t)) \text{ a.e.,}
\]

\[
h(x(t)) \leq 0 \text{ for all } t \in [S, T]
\]

\[
(x(S), x(T)) \in C \text{ and } z(S) = 0 .
\]
Here \( \tilde{F}(., .) : \mathbb{R}^n \to \mathbb{R}^{n+1} \) is the multifunction:

\[
\tilde{F}(t, x) := \{(e, \beta) \in \mathbb{R}^{n+1} \mid e \in F(t, x) \text{ and } L(t, x, e) \leq \beta \leq c'\}.
\]

in which \( c' \) is any number satisfying \( c' > c \), where \( c \) is as in (H2). We reproduce the preceding analysis in the proof of the theorem, now with reference to \((\tilde{x}(.), \tilde{z}(.))\), interpreted as an \( L^\infty\)-local minimizer for \((PA)\). This is permitted because all the relevant hypotheses are satisfied and since \((PA)\) has no integral cost term. The approximating ‘higher dimensional’ costate arcs \((p_i(.), p_i^0(.)\)) and associated arcs \((q_i(.), q_i^0(.)\)), which have an extra component, take the form \((p_i(.), p_i^0(.)) = (p_i(.), -\lambda_i)\) and \((q_i(.), -\lambda_i)\).

However we refine the analysis in one minor respect: this is to replace the estimate \((7.15)\) by the more refined relation,

\[
|\Delta_\gamma| \leq ||q_i(.)||_{TV} \times \left[ \eta_{F, \epsilon_i}^\delta(t^i_j) - \eta_{F, \epsilon_i}^\delta(t^i_{j-1}) \right] + \lambda_i \times \left[ \eta_{L, \epsilon_i}^\delta(t^i_j) - \eta_{L, \epsilon_i}^\delta(t^i_{j-1}) \right].
\]

in which the contributions to the estimates of the variation of the Hamiltonian on \([t^i_j, t^i_{j-1}]\), from the two components of \((q_i(.), (q_i^0(.) = \lambda_i))\), are now separated out. Here, \( \eta_{F, \epsilon_i}^\delta \) and \( \eta_{L, \epsilon_i}^\delta \) are the perturbed cumulative variation functions of \( F(., .) \) and \( L(., .) \) respectively.

We thereby arrive at a set of conditions from which may be deduced all the assertions of the theorem, when the integral cost term is present, with reference to the \( L^\infty\)-local minimizer \( \tilde{x}(.) \) for (P).

**Appendix**

*Proof of Proposition 2.1:* (a): We prove the first assertion. Proof of the second assertion is analogous. Take any \( \epsilon > 0 \) such that \( \eta^\delta_k(T) < +\infty \). Fix \( \delta \in (0, \delta) \). Take any \( x \in \tilde{x}(\bar{s}) + \delta B \), \( a \in A \) and

\[
v \in \limsup_{s \downarrow \bar{s}} F(s, x, a).
\]

By definition of the ‘lim sup’, there exists \( s_i \downarrow \bar{s} \) and \( v_i \to v \) such that

\[
v_i \in F(s_i, x, a) \text{ for all } i \text{ and } v_i \to v \text{ as } i \to \infty.
\]

The assertion (a) will follow if we can show that, also,

\[
v \in \liminf_{s \downarrow \bar{s}} F(s, x, a), \quad (7.23)
\]

i.e. the ‘lim sup’ and ‘lim inf’ coincide, in which case the limit exists. To show \((7.23)\) we take an arbitrary sequence \( t_j \downarrow \bar{s} \). By eliminating elements in the sequence \( \{(s_i, v_i)\} \), we can arrange that, for every \( j \), \( \bar{s} \leq s_j < t_j \), \( t_j - \bar{s} \leq \epsilon \) and \( x \in \tilde{x}(t) + \delta B \) for all \( t \in [\bar{s}, t_j] \), \( j = 1, 2, \ldots \), for all \( a \in A \). But then, since \( t_j - s_j \leq \epsilon \) and by an earlier listed ‘elementary’ property of the \((\delta, \epsilon)\)-perturbed cumulative variation function,

\[
d_H(F(t_j, x, a), F(s_j, x, a)) \leq \eta^\delta_k(t_j) - \eta^\delta_k(s_j).
\]

28
This means that, for each \( j \), there exists \( w_j \in F(t_j, x, a) \) and
\[
|v_j - w_j| \leq \eta^\delta_k(t_j) - \eta^\delta_k(s_j) .
\]

We know however that, since \( \eta^\delta_k(.) \) is a finite valued, monotone function, it has a right limit \( \eta^\delta_k(\bar{s}^+) \) at \( \bar{s} \). Hence
\[
\lim_{j \to \infty} |v_j - w_j| \leq \lim_{j \to \infty} \left( \eta^\delta_k(t_j) - \eta^\delta_k(s_j) \right) \leq \eta^\delta_k(\bar{s}^+) - \eta^\delta_k(\bar{s}^+) = 0 .
\]

It follows that \( v_j - w_j \to 0 \). But then \( v = \lim_j v_j = \lim_j w_j \). Since \( t_j \downarrow \bar{s} \) was an arbitrary sequence, we conclude \((7.23)\). We have confirmed (a).

(b) These assertions follow from (a), together with the compactness of the set \( A \) and of the \( \delta \) balls about \( \bar{x}(\bar{s}) \) and \( \bar{x}(\bar{t}) \), and with the assumed continuity properties of \((x, a) \to F(t, x, a)\).

(c) Let \( A \) be the empty or countable subset of \((S, T)\) comprising points at which the finite-valued monotone function \( \eta^\delta_k(.) \) is discontinuous. Fix a point \( t \in (S, T) \setminus A \), \( a \in A \) and \( x \in \bar{x}(t) + \delta B \). Take any \( \rho > 0 \). Since \( \eta^\delta_k(.) \) is continuous at \( t \), we may choose \( \gamma > 0 \) such that
\[
\eta^\delta_k(t + \gamma) - \eta^\delta_k(t - \gamma) \leq \rho .
\]

So, for any \( t' \in [S, T] \) such that \(|t' - t| \leq \rho \wedge \bar{\epsilon}|\),
\[
\sup \{d_H(F(t', x, a), F(t, x, a)) \mid x \in \bar{x}(t) + \delta B, a \in A\} \leq \eta^\delta(t' \vee t) - \eta^\delta(t' \wedge t)
\leq \eta^\delta(t + \gamma) - \eta^\delta(t - \gamma) \leq \rho .
\]

The continuity properties of \( F(., x, a) \) at \( t \) have been confirmed.

**Proof of Prop. 7.24.** Let \( \bar{F}(.,.) : [S, T] \times \mathbb{R}^n \times A \to \mathbb{R}^n \) be a multifunction such that, for \((t, x, a) \in [S, T] \times \mathbb{R}^n \times A\),
\[
\bar{F}(t, x, a) = \begin{cases} 
F(S^+, x, a) & \text{if } t = S, x \in \bar{x}(S) + \delta B \text{ and } a \in A \\
F(t, x, a) & \text{otherwise} .
\end{cases}
\]

(Note that \( \bar{F}(t, x, a) \) is a modified version of \( F(t, x, a) \) that differs only at the left endpoint \( t = S \).) Write \( \bar{\eta}^\delta_k(.) \) to denote the \((\delta, \epsilon)\)-perturbed cummulative variation function of \( t \to \bar{F}(t, ., .) \) along \( \bar{x}(.) \), for \( a \in A \).

Fix \( t \in (S, T) \). Take \( \delta \in (0, \bar{\delta}) \) and \( \epsilon > 0 \) such that \( \eta^\delta_k(T) < +\infty \). Let \( T = \{t_0 = S, \ldots, t_N = t\} \) be an arbitrary partition of \([S, T] \). Take an arbitrary sequence \( s_j \downarrow S \). For \( j \) sufficiently large,
\[
\eta^\delta_k(t) \geq \sup \{d_H(F(s_j, x, a), F(S, x, a)) \mid x \in \bar{x}([S, s_j]) + \delta B, a \in A\} \\
+ \sup \{d_H(F(s_j, x, a), F(t_1, x, a)) \mid x \in \bar{x}([s_j, t_1]) + \delta B, a \in A\} \\
+ \sum_{i=1}^{N-1} \sup \{d_H(F(t_{i+1}, x, a), F(t_i, x, a)) \mid x \in \bar{x}([t_i, t_{i+1}]) + \delta B, a \in A\} .
\]

29
In view of Prop. 2.1, we may pass to the limit as \( j \to \infty \) in this relation to obtain:

\[
\eta^\delta_k(t) \geq \sup \left\{ d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \bar{x}(S) + \delta B, a \in A \right\} \\
+ \sup_{N-1} \left\{ d_H(F(S^+, x, a), F(t_1, x, a)) \mid x \in \bar{x}([S, t_1]) + \delta B, a \in A \right\} \\
+ \sum_{i=1}^{N} \sup \left\{ d_H(F(t_{i+1}, x, a), F(t_i, x, a)) \mid x \in \bar{x}([t_i, t_{i+1}]) + \delta B, a \in A \right\} .
\]

Since the partition \( T \) was an arbitrary partition such that \( \text{diam}\{T\} \leq \epsilon \) it follows that

\[
\eta^\delta_k(t) \geq \sup \left\{ d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \bar{x}(S) + \delta B, a \in A \right\} + \hat{\eta}^\delta_k(t). \tag{7.24}
\]

Take again an arbitrary partition \( T = \{t_0 = S, \ldots, t_N = t\} \) of \([S, t]\). Let \( \bar{\delta}, \delta \) and \( \epsilon \) be as before. We have

\[
\hat{\eta}^\delta_k(t) \geq \sup_{N-1} \left\{ d_H(F(S^+, x, a), F(t_1, x, a)) \mid x \in \bar{x}([S, t_1]) + \delta B, a \in A \right\} \\
+ \sum_{i=1}^{N} \sup \left\{ d_H(F(t_{i+1}, x, a), F(t_i, x, a)) \mid x \in \bar{x}([t_i, t_{i+1}]) + \delta B, a \in A \right\}. \tag{7.25}
\]

But by the triangle inequality we have, for each \( x \in \{\bar{x}(t) + \delta B \mid t \in [S, t_1]\} \) and \( a \in A, \)

\[
d_H(F(S^+, x, a), F(t_1, x, a)) \geq d_H(F(S, x, a), F(t_1, x, a)) - d_H(F(S^+, x, a), F(S, x, a)).
\]

Furthermore,

\[
\max d_H(F(S^+, x, a), F(t_1, x, a)) \geq \\
\min d_H(F(S, x, a), F(t_1, x, a)) - \max \{d_H(F(S^+, x, a), F(S, x, a))\},
\]

where, in each term, the max is taken over \( (x, a) \in \{\bar{x}(t) + \delta B \mid t \in [S, t_1]\} \times A. \)

Noting that \( T \) was an arbitrary partition such that \( \text{diam}\{T\} \leq \epsilon \), we deduce from (7.25) that

\[
\hat{\eta}^\delta_k(t) \geq \eta^\delta_k(t) - \max \{d_H(F(S^+, x, a), F(S, x, a)) \mid (x, a) \in \{\bar{x}(t) + \delta B \mid t \in [S, t_1]\} \times A\}.
\]

This relation combines with (7.24) to yield

\[
0 \leq \eta^\delta_k(t) - \hat{\eta}^\delta_k(t) - \max \{d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \bar{x}(S) + \delta B, a \in A\} \leq \Delta(\epsilon, \delta),
\]

in which

\[
\Delta(\epsilon, \delta) := \max \{d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \{\bar{x}(t) + \delta B \mid t \in [S, (S + \epsilon) \land T]\} \}, a \in A\}
\]

\[
- \max \{d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \bar{x}(S + \delta B), a \in A\}.
\]

Since, as is easily shown, \( F(S^+, \ldots) \) has modulus of continuity \( \theta(.) \) on \( \{\bar{x}(S) + \delta B\} \times A, \)

where \( \theta(.) \) is as in hypothesis (C2) and \( \bar{x}(\cdot) \) is continuous,

\[
\lim_{\epsilon \downarrow 0} \Delta(\epsilon', \delta) = 0. \]
We deduce that
\[ \eta^\delta(t) = \eta^\delta(t) + \max \{ d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \bar{x}(S) + \delta B, a \in A \} . \]
In the limit as \( \delta \downarrow 0 \) we obtain
\[ \eta(t) = \eta(t) + \sup_{a \in A} d_H(F(S^+, \bar{x}(S), a), F(S, \bar{x}(S), a)) . \] (7.26)
Since \( \eta(t) \) and \( \eta(t) \) coincide for \( t < T \), we have shown that
\[ \eta(t) = \eta(t) + \sup_{a \in A} d_H(F(S^+, \bar{x}(S), a), F(S, \bar{x}(S), a)) \text{ for } t \in [S, T) . \] (7.27)
A similar analysis to that above yields
\[ \hat{\eta}(T) = \hat{\eta}(T) + \sup_{a \in A} d_H(F(T^-, \bar{x}(T), a), F(T, \bar{x}(T), a)) . \] (7.28)
Combining (7.26) (in the case \( t = T \)) and (7.28) yields
\[ \eta(T) = \eta(T) + \sup_{a \in A} d_H(F(S^+, \bar{x}(S), a), F(S, \bar{x}(S), a)) + \sup_{a \in A} d_H(F(T^-, \bar{x}(T), a), F(T, \bar{x}(T), a)) . \] (7.29)

It follows from (7.27) that
\[ \hat{\eta}(t) - \hat{\eta}(s) = \eta(t) - \eta(s) , \text{ for all } [s, t] \subset (S, T) . \] (7.30)

The remaining assertions of the proposition will follow from (7.27) and (7.29), if we can verify the two assertions: \( \hat{\eta}(.) \) is right continuous at \( S \) and left continuous at \( T \). We prove the first assertion. The proof of the second is similar.

Suppose the first assertion is not true. Then there exists \( \alpha > 0 \) such that \( \hat{\eta}(t) - \hat{\eta}(S) = 0 \geq \alpha \) for all \( t \in [S, T] \). Choose any \( \delta \in (0, \delta) \) and \( \epsilon > 0 \) such that \( \hat{\eta}^\delta(t) < \infty \). Then
\[ \hat{\eta}^\delta(t) \geq \alpha \text{ for all } t \in [S, T] . \]
Notice that the choice of \( \epsilon \) does not depend on the choice of \( \alpha \). We can then impose that
\[ \Delta(\epsilon, \delta) < \alpha/8 . \]

By Prop 2.1, we can find \( \bar{s} > 0 \) such that
\[ \max_{x \in [S] + \delta B, a \in A} d_H(F(\bar{s}, x, a), F(S^+, x, a)) \leq \alpha/4 . \]

By the properties of the supremum, we can choose a partition \( \{ s_0, ..., s_N \} \) of \( [S, \bar{s}] \), of diameter at most \( \epsilon \), such that
\[ \hat{\eta}^\delta(\bar{s}) \leq \max_{x \in [S, s_1] + \delta B, a \in A} d_H(F(s_1, x, a), F(S^+, x, a)) + \alpha/4 + \Sigma_2 \]
\[ = \Delta(\epsilon, \delta) + \max_{x \in [S, s_1] + \delta B, a \in A} d_H(F(\bar{s}, x, a), F(S^+, x, a)) + \alpha/4 + \Sigma_2 \] (7.31)
\[ \leq \alpha/8 + \alpha/4 + \Sigma_2 + \alpha/4 = \Sigma_2 + 5\alpha/8 , \] (7.32)
where
\[
\Sigma_2 := \sum_{i=1}^{N-1} \max_{x \in \mathcal{B}([s_i, s_{i+1}]) + \delta \mathcal{B}} d_H(F(s_{i+1}, x, a), F(s_i, x, a)).
\]

But we can also choose a partition \( \{t_0, \ldots, t_M\} \) of \([S, s_1]\) (which will have diameter not greater than \(\varepsilon\)) such that
\[
\alpha \leq \tilde{\eta}^\delta(s_1) \leq \Sigma_1 + \alpha/4,
\]
where
\[
\Sigma_1 := \sum_{i=0}^{N-1} \max_{x \in \mathcal{B}([t_i, t_{i+1}]) + \delta \mathcal{B}} d_H(F(t_{i+1}, x, a), F(t_i, x, a)).
\]

It follows that
\[
\Sigma_1 \geq 3\alpha/4.
\]

But since the concatenation of \(\{t_0, \ldots, t_M\}\) and \(\{s_1, \ldots, s_N\}\) is a partition of \([S, \tilde{s}]\), of diameter no greater than \(\varepsilon\), we know from the preceding inequality that
\[
\tilde{\eta}^\delta(\tilde{s}) \geq \Sigma_1 + \Sigma_2 \geq \Sigma_2 + 3\alpha/4.
\]

But this contradicts (7.32). The assertion has been confirmed.

**Proof of Lemma (7.2):** Notice that
\[
m_i(S) = m_0^i \quad \text{and} \quad ||m_i(.)||_{TV} \leq \eta(T) - \eta(S) \quad \text{for all } i.
\]

These relations follow from the definition of the \(m_i(.)\)'s and (H3).

Take sequences \(\delta_m \downarrow 0\) and \(\epsilon_n \downarrow 0\). For each \((m, n)\) let \(\mathcal{B}_{m,n}\) be the (possibly empty,) countable set comprising points of discontinuity of the monotone function \(\eta_{\delta_m}^n(.)\). Fix \((m, n)\).

For each \(i\), define the function \(\bar{m}_i(.) : [S, T] \rightarrow \mathbb{R}^n\), which can be interpreted as an interpolant of the values of \(m(.)\) at grid points, as follows:
\[
\bar{m}_i(t) := m_i(t_k) + (m_i(t_{k+1}) - m_i(t_k)) \times \frac{\eta_{\delta_m}^n(t) - \eta_{\delta_m}^n(t_k)}{\eta_{\delta_m}^n(t_{k+1}) - \eta_{\delta_m}^n(t_k)}
\]
if \(t \in [t_k, t_{k+1})\), for some \(k = 0, \ldots, N_i - 1\). Set \(\bar{m}_i(T) := m_i(T)\).

(The rightside of (7.34) is interpreted as \(m_i(t_k)\) if \(\eta_{\delta_m}^n(t_{j+1}) - \eta_{\delta_m}^n(t_j) = 0\).)

**Claim:**
\[
\bar{m}_i(S) = m_i(S) \quad \text{and} \quad \bar{m}_i(T) = m_i(T) \quad \text{for all } i
\]
\[
\bar{m}_i(t) - m_i(t) \rightarrow 0 \quad \text{for all } t \in [S, T] \setminus \mathcal{B}_{m,n}
\]
\[
|\bar{m}_i(t) - \bar{m}_i(s)| \leq \eta_{\delta_m}^n(t) - \eta_{\delta_m}^n(s)
\]
\[
\quad \text{for all } [s, t] \subset [S, T] \text{ and } i \geq I(\delta_m, \epsilon_n).
\]
We verify the claim. (7.35) follows from the fact that $m_i(.)$ and $\tilde{m}_i(.)$ coincide at mesh points, which include $S$ and $T$. Consider next (7.36). Take any $t \in (S, T) \setminus \mathcal{B}$. Then

$$|\tilde{m}_i(t) - m_i(t)| = |\tilde{m}_i(t) - \tilde{m}_i(t_{j_i}^i)| \leq \eta^\delta_{\epsilon_n}(t_{j_i+1}) - \eta^\delta_{\epsilon_n}(t_{j_i}) ,$$

for each $i$, where $j_i$ is the unique index value satisfying $t \in [t_{j_i}^i, t_{j_i+1}^i)$, by (H1). But from the definition of $\tilde{m}_i(.)$, it follows that there exists a normalized function of bounded variation $\tilde{m}_i(.)$ for $t \in [S, T]$ such that, for some $j, k$ such that $j \leq k$.

Consider finally assertion (7.37). Take any $[s, t] \subset [S, T]$. Then either

Case 1: $[s, t] \subset [t_j^i, t_{j+1}^i]$ for some $j \in \{0, \ldots, N_i - 1\}$

Case 2: $s \in [t_{j-1}^i, t_j^i]$ and $s \in [t_k^i, t_{k+1}^i]$ for some $j, k$ such that $j \leq k$.

We consider only Case 2. (Verifying Case 1 is similar, but simpler.) We have

$$\tilde{m}_i(t) - \tilde{m}_i(s) = \tilde{m}_i(t_j^i) - \tilde{m}_i(s) + \sum_{l=j}^{k-1} (m(t_{l+1}) - m(t_l)) = \tilde{m}(t) - m(t_k) \quad (7.38)$$

(We have used here the fact that $\tilde{m}_i(.)$ and $m(.)$ coincide at points $t_j^i$, $j = 1, \ldots, N_i$.) But from the definition of $\tilde{m}_i(.)$, and in view of (H3),

$$|\tilde{m}(t_j^i) - \tilde{m}(s)| = (\eta^\delta_{\epsilon_n}(t_j^i) - \eta^\delta_{\epsilon_n}(s)) \times \frac{m(t_j^i) - m(t_{j-1})}{\eta^\delta_{\epsilon_n}(t_j^i) - \eta^\delta_{\epsilon_n}(t_{j-1})} \leq \eta^\delta_{\epsilon_n}(t_j^i) - \eta(s) .$$

$$|\tilde{m}(t) - \tilde{m}(t_k^i)| = (\eta^\delta_{\epsilon_n}(t) - \eta^\delta_{\epsilon_n}(t_k^i)) \times \frac{m(t_k^i) - m(t_{k+1})}{\eta^\delta_{\epsilon_n}(t_k^i) - \eta^\delta_{\epsilon_n}(t_{k+1})} \leq \eta^\delta_{\epsilon_n}(t) - \eta^\delta_{\epsilon_n}(t_k^i) .$$

It follows from (7.37) and (H3) that

$$|\tilde{m}_i(t) - \tilde{m}_i(s)| \leq \eta^\delta_{\epsilon_n}(t_j^i) - \eta^\delta_{\epsilon_n}(s) + \sum_{l=j}^{k-1} \eta^\delta_{\epsilon_n}(t_{l+1}) - \eta^\delta_{\epsilon_n}(t_l) + \eta(t) - \eta(t_k^i) = \eta^\delta_{\epsilon_n}(t) + 0 + \ldots + 0 - \eta^\delta_{\epsilon_n}(s) = \eta^\delta_{\epsilon_n}(t) - \eta^\delta_{\epsilon_n}(s) .$$

We have confirmed (7.37) (in the Case 2) and thereby verified the claim.

In view of (H1), we can deduce from (7.35) and (7.37) that the total variation of elements in the sequence $\{\tilde{m}_i(.)\}$ are uniformly bounded and that their initial values are uniformly bounded. It follows that there exists a normalized function of bounded variation $m(.) : [S, T) \to \mathbb{R}^n$ and a countable set $\tilde{A} \subset (S, T)$ such that, for some subsequence,

$$\tilde{m}_i(t) \to m(t) \quad \text{for all} \quad t \in [S, T] \setminus \tilde{A}. \quad (7.39)$$

But then, by (7.36),

$$m_i(t) \to m(t) \quad \text{for all} \quad t \in [S, T] \setminus (\tilde{A} \cup \mathcal{B}_{m,n}) ,$$

33
Up to this point the index values $m, n$ have been fixed. We now let them vary. Define the countable set

$$A := \hat{A} \cup_{m,n} B_{m,n}.$$ 

Passing to the limit as $i \to \infty$ in (7.37) we deduce that, for every $[S,T] \setminus A$, we have

$$|m(t) - m(s)| \leq \eta_{\epsilon_n}^{\delta_m}(t) - \eta_{\epsilon_n}^{\delta_m}(s)$$

for all $[s,t] \subset [S,T]$ such that $s, t \notin (S,T) \setminus A$. Fixing $m$ and passing to the limit as $n \to \infty$ yields

$$|m(t) - m(s)| \leq \eta_{\epsilon_n}^{\delta_m}(t) - \eta_{\epsilon_n}^{\delta_m}(s).$$

Then, passing to the limit as $m \to \infty$ in this relation, we obtain

$$|m(t) - m(s)| \leq \eta(t) - \eta(s).$$

This inequality is valid, we recall, for all $[s,t] \subset [S,T]$ such that $s, t \in (S,T) \setminus A$. It implies however

$$|m(t) - m(s)| \leq \eta^*(t) - \eta^*(s).$$

for all subintervals $[s,t] \subset [S,T]$, since the regularized cumulative variation $\eta^*(\cdot)$ coincides with $\eta(\cdot)$ on the complement of a countable subset of $[S,T]$ that includes $\{S\} \cup \{T\}$ and since $m(\cdot)$ and $\eta^*(\cdot)$ are right continuous on $(S,T)$.

**Proof of Lemma 2.3** Write $\eta_{\epsilon,A}(\cdot)$ for the $(\delta, \epsilon)$ perturbed cumulative variation with respect to $A$, etc. Take $\delta > 0$ and $\epsilon > 0$ such that $\eta_{\epsilon,A}(\cdot) < \infty$ for every $\delta \in (0, \delta)$, $\epsilon \in (0, \epsilon]$. Take also any $[s,t] \subset [S,T]$. We shall show that

$$\eta_{A_1}^\delta(t) - \eta_{A_1}^\delta(s) \leq \eta_{A}^\delta(t) - \eta_{A}^\delta(s).$$

(7.40)

Since this relation is valid for all $\delta > 0$ sufficiently small, we can deduce (2.6) by passing to the limit as $\delta \downarrow 0$.

If $s = S$ then (7.40) is obvious, since $\eta_{A_1}^\delta(S) = \eta_{A}^\delta(S) = 0$ and since $\eta_{A_1}^\delta(t) \leq \eta_{A}^\delta(t)$. The latter inequality is true because the left side involves taking the supremum over a smaller set, as compared with the right side. So we may assume that $s > S$.

Define $\eta_{\epsilon,A}^\delta([s,t])$ to be the $(\delta, \epsilon)$ perturbed cumulative variation with respect to $A$, when the underlying time interval is changed from $[S,T]$ to the smaller set $[s,T]$. It is clear that

$$\eta_{\epsilon,A_1}^\delta(t) \leq \eta_{\epsilon,A}^\delta(t).$$

(7.41)

because the left side involves taking the supremum over a small set, in relation to the right side.

By consideration of arbitrary partitions of $[S,s]$ of diameter not greater than $\epsilon$, as well as their extensions to form partitions of the larger interval $[S,t]$, we deduce that

$$\eta_{\epsilon,A}^\delta(t) - \eta_{\epsilon,A}^\delta(s) \geq \eta_{\epsilon,A}^\delta([s,t]).$$
Passing to the limit as $\delta \downarrow 0$ yields
\[ \eta_{\delta}^A(t) - \eta_{\delta}^A(s) \geq \eta_{\delta}^A([s, t]). \] (7.42)

On the other hand, consideration of arbitrary partitions of $[S, t]$ of diameter not greater than $\epsilon$, as their refinements to include the intermediate point $s$, we deduce that there exists continuity modulus $\gamma(.)$ such that
\[ \eta_{\epsilon, A}^\delta(t) - \lim_{t' \uparrow s} \eta_{\epsilon, A}^\delta(t') \leq \eta_{\epsilon, A}^\delta([s, t]) + \gamma(\epsilon). \]

Noting that $\lim_{t' \uparrow s} \eta_{\epsilon, A}^\delta(t') \leq \eta_{\epsilon, A}^\delta(s)$ and passing to the limit as $\delta \downarrow 0$ yields
\[ \eta_{A}^\delta(t) - \eta_{A}^\delta(s) \leq \eta_{A}^\delta([s, t]). \] (7.43)

(7.40) now follow from (7.41), (7.42) and (7.43).
