SEARCH FOR NON-SM HIGGSES AT LEP

AURA ROSCA
Institut für Physik, Invalidenstr. 110,
D-10115 Berlin, Germany

The four LEP experiments, ALEPH, DELPHI, L3 and OPAL, have searched for Higgs bosons predicted by a large number of extensions of the Standard Model. Flavor independent searches are presented for the $h^0 Z^0$ process in which the $h^0$ decays hadronically. Search results are also presented for fermiophobic Higgs bosons, invisibly decaying Higgs bosons, charged Higgs bosons and the neutral Higgs bosons in the MSSM.

1 Introduction

Since we have no experimental evidence for the Standard Model (SM) Higgs particle, we must test more complicated scenarios beyond the SM. Several extensions of the SM introduce additional Higgs doublets and singlets. In this work we present results on the 2HDM Higgses. The 2HDM is a minimal extension of the SM, in the sense that only one additional doublet is introduced in the theory. After the symmetry is broken the Higgs spectrum consists of five particles: two CP-even neutral scalars ($h^0$ and $H^0$), a CP-odd neutral scalar ($A^0$) and a charged pair ($H^\pm$). The properties of the Higgs bosons are defined by six free parameters: four Higgs masses, the ratio of the vacuum expectation values of the two fields, $\tan \beta$, and the mixing angle in the neutral CP-even sector, $\alpha$. The Higgs couplings with the bosons and fermions control Higgs production and decays. Particularly, the Higgs couplings with the fermions must be limited, in order to suppress FCNCs (Flavor Changing Neutral Currents) at the tree level. There are exactly two possibilities for the Higgs boson to couple to the fermions: only one doublet couples with fermions, and the other does not couple to quarks or leptons, and this determines the structure of the 2HDM of Type I; or one doublet couples to down-type fermions, and the second doublet couples with the up-type fermions, and this determines the structure of the 2HDM of Type II.

2 Search for the Higgs bosons beyond the SM
2.1 Flavor independent searches

For certain regions of the parameter space the Higgs boson decay into a pair of $b\bar{b}$ quarks can be suppressed with respect to the SM values, while decays to charm quark or gluon pairs are enhanced. Therefore, flavor independent searches have been performed. The experiments have updated their search for a scalar boson which is produced in association with the $Z^0$ and which decays hadronically with a BR = 1. These analyses use the same topologies as for the SM Higgs boson search, but do not make use of the b-tag. In the absence of a signal, the results are usually given in terms of excluded regions in the plane $m_h$ versus a SM cross section scaling factor, $\xi^2$. As an example we show in Fig. 1 the results obtained by the ALEPH collaboration combining energies up to 209 GeV. A Higgs boson produced with the SM cross section and decaying hadronically with a BR = 1 is ruled out by ALEPH up to the mass of 109.4 GeV. Similar results have been obtained by the OPAL collaboration.

2.2 Fermiophobic decays

Fermiophobic decays due to suppressed couplings between the Higgs bosons and the fermions can appear in several non-minimal models, as for example 2HDM of Type I. At masses below 90 GeV the Higgs boson decays dominantly into $\gamma\gamma$, while at higher masses it decays mostly into $WW^*$ and $ZZ^*$. The four LEP experiments searched for a photonically decaying Higgs boson produced in association with a $Z^0$ and leading to the following final states: $\gamma\gamma q\bar{q}$, $\gamma\gamma \nu\bar{\nu}$, $\gamma\gamma \ell^+\ell^-$. Since no indication for a signal was found in the data, the negative search result is given in terms of upper limits of the BR($h^0 \rightarrow \gamma\gamma$), assuming a SM production cross section for the Higgs boson. The limits are shown in Fig. 2 for the OPAL collaboration. In the fermiophobic model, the observed mass limit is 105.5 GeV. Similar results have been obtained by the other collaborations.

2.3 Invisible decays

Invisible Higgs boson decays can appear in different models as MSSM, majoron models, models with extra-dimensions, etc. At LEP energies it can be produced via the Higgs-Strahlung mechanism, $e^+e^- \rightarrow h^0Z^0$, followed by the decay of $h^0$ into undetectable final states. The signatures for such process are either 2 jets and missing energy in the event, or a lepton pair and missing energy. The analyses make use of the kinematic constraint $m_{ll} \approx m_Z$. No excess with respect
to the SM is observed in the data. The results are expressed as excluded regions in the plane $m_h$ versus $\xi^2$, with $\xi^2$ defined as the ratio of the Higgs boson production cross section times the branching fraction for the invisible Higgs decay, normalized to the SM cross section. For $\xi^2=1$ the lower limit on the mass of an invisibly decaying Higgs boson is set by ALEPH at 114.1 GeV.

Similar results have been obtained by the other collaborations.

2.4 Charged Higgs Bosons

Charged Higgs bosons are predicted in 2HDMs. At LEP energies, they are produced in pairs, with a cross section which depends only on the Higgs boson mass. The branching ratios are not predicted by the model. Possible decay modes are $q\bar{q}$, $\tau\nu_\tau$, and $W^*A^0$. In 2HDM of Type II it is assumed that the first two fermionic decay modes are the only possible ones. The searches cover all the possible final states: four jet final state, the semileptonic and fully leptonic final states. The mass limits are expressed as a function of $\text{BR}(H^+ \to \tau^+\nu_\tau)$. The main background is from the process $e^+e^- \to W^+W^-$ which sets the scale for the limits in the hadronic and semileptonic searches. Negative search results are shown in Fig. 3 combining the data from the four LEP experiments at energies up to 209 GeV. The lowest mass limit obtained at $\text{BR}(H^+ \to \tau^+\nu_\tau)$=0.4 is 78.5 GeV, with a median expectation of 78.9 GeV. A small excluded "island" appears in Fig. 3 for $\text{BR}(H^+ \to \tau^+\nu_\tau)$=0, where the search sensitivity above the $W^+W^-$ background peak becomes sufficient to exclude this small region. In 2HDM of Type I, at high $\tan\beta$, the decay mode $H^\pm \to W^\pm A^0$ can become dominant, with a branching ratio which depends on $\tan\beta$ and the mass difference between the charged Higgs and the CP-odd neutral Higgs. The OPAL collaboration carries out such a search by considering new decay modes. Results are expressed as excluded regions in the $(m_{H^\pm}, m_A)$ plane.

2.5 Neutral Higgs Bosons in the MSSM

The MSSM is a 2HDM of Type II. The Higgs boson production cross sections and the branching ratios depend on the model parameters. We use a constrained model with only seven parameters: the mass scale of the sfermions $M_{\text{SUSY}}$, the gaugino mass parameter $M_2$, the supersymmetric Higgs mass parameter $\mu$, the trilinear coupling of the Higgs boson to the squarks A, the ratio of the vacuum expectation values of the two fields, the mass of the CP-odd neutral scalar $m_A$.
Table 1: Limits on $m_{h}$-max and no-mixing scenarios.

| Scenario   | $m_{h}$ limit (GeV) | $m_{A}$ limit (GeV) | Excluded $\tan \beta$ |
|------------|---------------------|---------------------|------------------------|
| $m_{h}$-max| 91.0                | 91.9                | $0.5 < \tan \beta < 2.4$ |
| no-mixing  | 91.5                | 92.2                | $0.8 < \tan \beta < 9.6$ |

and the gluino mass $m_{g}$. These parameters are further set to specific values which define three benchmark scans. In the no-mixing scenario, the parameter which controls the mixing in the stop sector, $X_{t} = A - \mu \cos \beta$, is chosen to be zero. The other parameters are chosen to be $M_{\text{SUSY}} = 1$ TeV, $M_{2} = 200$ GeV, $\mu = -200$ GeV and $m_{g} = 800$ GeV and the scan is done over $0.4 < \tan \beta < 50$ and 4 GeV < $m_{A} < 1$ TeV. For the case of the maximal mixing in the stop sector, $X_{t} = 2M_{\text{SUSY}}$ and the other parameters take the same values as before. The maximum mass value of the $h^{0}$ is a function of $\tan \beta$. In the third scenario, called the large-$\mu$ scenario, the parameters are chosen such as to emphasize points in the parameter space where the Higgs decay mode into a $b\bar{b}$ pair is not dominant. These values are: $M_{\text{SUSY}} = 400$ GeV, $M_{2} = 400$ GeV, $\mu = -1$ TeV and $m_{g} = 200$ GeV.

The two Higgs production mechanisms, the Higgs-Strahlung process, and the $h^{0}A^{0}$ associate production, vary in relative importance as a function of $\tan \beta$. The $h^{0}Z^{0}$ production is dominant at low $\tan \beta$ and the MSSM phenomenology reduces to the SM one, while the $h^{0}A^{0}$ production becomes dominant at high $\tan \beta$. The dominant decays of the $h^{0}$ and $A^{0}$ Higgs bosons are into a pair of b-quarks and a pair of tau leptons. However, for several choices of parameters, the decays $h^{0} \to A^{0}A^{0}$, $h^{0} \to c\bar{c}$, $h^{0} \to gg$ and $h^{0} \to W^{+}W^{-}$ can become important.

No evidence for a signal was found in the data. The negative results are presented as excluded regions in the planes $[m_{h}, \tan \beta]$, $[m_{A}, \tan \beta]$, $[m_{h}, m_{A}]$ or $[m_{H^{\pm}}, \tan \beta]$. The 95% C.L. excluded region for the $m_{h}$-max scenario is shown in Fig. 4 combining the data from the four LEP experiments at energies up to 209 GeV. The lower limits on the Higgs masses and the excluded $\tan \beta$ ranges for the $m_{h}$-max and no-mixing scenarios are summarized in Tab. 1.

Acknowledgments

I would like to thank the members of the four LEP collaborations and the LEP Higgs working group for providing me plots and their help in preparing this talk. I am grateful to Thomas Hebbeker for reading carefully this paper.
