DESCRIPTION OF SOME WEIGHTED EXPONENTIAL CLASSES OF SUBHARMONIC FUNCTIONS

O.V. Okhlupina

E-mail: helga131081@yandex.ru

The role of subharmonic functions in such sections of analysis as complex and real analysis is very significant. Such classes of functions are closely related to analytic harmonic functions and make an important contribution to the general theory of potential and mathematical physics. In the works of R. Nevanlinna and W. Heiman, parametric representations of subharmonic classes in the plane of functions, whose characteristic has a power growth at infinity, are obtained. The question of whether similar representations are true for weighted classes that admit a stronger growth at infinity (for example, the exponential growth) arises in the theory of entire and meromorphic functions. In this article, classes of subharmonic functions with Nevanlinna characteristic that is summable with exponential weight in a complex plane are introduced for consideration, and the representing measures of functions of such classes are studied. When proving the results, methods of complex and functional analysis are used. An important role in the study is played by potentials based on the factors of the modified Weierstrass product. The proof of the main result is based on the use of auxiliary assertions formulated in the form of lemmas.

Keywords: subharmonic function; harmonic function; representing measures; the Nevanlinna’s characteristic.

Introduction

Let \( C \) be the complex plane. \( SH_{\alpha,\sigma}(C) \) (\( \sigma, \alpha \) are positive numbers) be the class of subharmonic functions \( u \) in \( C \) such that

\[
\int_{1}^{+\infty} T(r,u)e^{-\sigma r^\alpha} dr < +\infty,
\]

where \( T(r,u) \) is the Nevanlinna’s characteristic of subharmonic function \( u \), that is

\[
T(r,u) = \frac{1}{2\pi} \int_{-\pi}^{\pi} u^+(r \cos \varphi, r \sin \varphi) d\varphi, \quad u^+ = \max\{u,0\} \quad (\text{see} \ [1–4]).
\]

In complex and real analysis, potential theory and mathematical physics the value of subharmonic functions is very significant (see [1–3, 5]). In the works R. Nevanlinna and W. Hayman (e.g., see [1]) the obtained definition of a class of subharmonic in the plane of the functions, the characteristics of which have exponential growth at infinity. The question of whether faithful same parametric representation for the weight classes, allowing for stronger growth at infinity, say exponential growth, occurs in the theory of entire and meromorphic functions (see [6]).

This paper studied the representing measures of the functions of class \( SH_{\alpha,\sigma}(C) \), as well as the necessary and sufficient condition for such measures.

Statement of the main result

Let \( \sigma, \alpha > 0, \ z, \zeta \in C, \ \zeta \neq 0, \ p(\lvert \zeta \rvert) = \max\left[ \sigma / \lvert \zeta \rvert^\alpha, 1 \right], \) where \([a]\) is the integer part of a real number \( a \).

\[
A_p(z, \zeta) = \left(1 - \frac{z}{\zeta}\right) \exp \left( \sum_{j=1}^{p(\lvert \zeta \rvert)} \frac{1}{j!} \left(\frac{z}{\zeta}\right)^j \right)
\]

is a factor of the modified product by K. Weierstrass (see [7, 8]).
Theorem 1. Let \( u \in SH_{\alpha,\sigma}(C) \), \( \mu \) is representing measure of a function \( u \). Then \( \mu \) satisfies the condition:

\[
\int_{1}^{+\infty} \frac{n(t)e^{-\sigma \alpha \alpha}}{t^\alpha} \, dt < +\infty,
\]

(1)

where \( n(t) = \mu(D_t), \ |t| < t \).

The opposite is also true: let \( \mu \) is some non-negative Borel measure in \( C \), satisfying the condition (1), then it is possible to build explicitly subharmonic function of class \( SH_{\alpha,\sigma}(C) \), \( \forall \sigma': \sigma' > \frac{1}{e\alpha} + \sigma e^\alpha \), for which \( \mu \) will be a representing measure.

Proof of auxiliary assertions

We require some auxiliary assertions for the proof of the theorem.

Lemma 1. Let \( \psi(R) \) is a non-negative monotonically increasing function, for which

\[
\int_{1}^{+\infty} \psi(x)e^{-\sigma \alpha x} \, dx < +\infty,
\]

(2)

where \( \alpha > 0 \). Then

\[
\lim_{R \to +\infty} \frac{\psi(R)e^{-\sigma \alpha R}}{R^{\alpha-1}} = 0.
\]

Proof. The convergence of the integral (2) implies that the \( \lim_{R \to +\infty} \int_{R}^{+\infty} \psi(x)e^{-\sigma \alpha x} \, dx = 0 \).

Let \( \varphi(R) = \int_{R}^{+\infty} \psi(x)e^{-\sigma \alpha x} \, dx \). It is clear that \( \varphi(R) \geq \psi(R) \int_{R}^{+\infty} e^{-\sigma \alpha x} \, dx \). We find the asymptotics of the last integral by applying the L'Hospital's rule.

\[
\lim_{R \to +\infty} \frac{\varphi(R)e^{-\sigma \alpha R}}{R^{\alpha-1}} = \lim_{R \to +\infty} \frac{e^{-\sigma \alpha R}}{R^{\alpha-1}} = \frac{1}{\sigma \alpha}.
\]

Therefore, \( \lim_{R \to +\infty} \frac{\psi(R)e^{-\sigma \alpha R}}{R^{\alpha-1}} = 0 \). That is \( \lim_{R \to +\infty} \psi(R) = 0 \).

The lemma is proved.

Lemma 2. Let \( \varphi(x) = e^{-\sigma \alpha x}, \quad x \in R_+, \quad R_+ = \{x \in R : x \geq 0\}, \quad \varepsilon_x = \frac{1}{x^\alpha}. \) Then \( \varphi(x + \varepsilon_x) = e^{\varphi(x)} \cdot e^{\beta(x)}, \) where \( \beta(x) = o \left( \frac{1}{x} \right) \) when \( x \to +\infty \).

Proof. It follows easily from the following simple arguments. It is clear that

\[
(1 + y)^\alpha = 1 + \alpha y + o \left( y^2 \right) \quad \text{when} \quad y \to 0.
\]

So \( \sigma(x + \varepsilon_x)^\alpha = \sigma x^\alpha \left( 1 + \varepsilon_x \right)^\alpha = \sigma x^\alpha + \frac{\alpha \sigma}{x} + o \left( \frac{1}{x^{\alpha+1}} \right) \) when \( x \to +\infty \).

Then, \( e^{\varphi(x + \varepsilon_x)} = e^{\varphi(x)} \cdot e^{\beta(x)}, \) where \( \beta(x) = o \left( \frac{1}{x} \right) \) when \( x \to +\infty \).

The lemma is proved.
Lemma 3. Let \( u \) is an arbitrary subharmonic function in \( C \), while it admits a representation in the form:
\[
    u(z) = \int_C \ln |A_p(z, \zeta)| d\mu(\zeta) + h(z),
\]
where \( z, \zeta \in C \), \( \mu(\zeta) \) is an arbitrary non-negative Borel measure in \( C \), such that
\[
    n(r) = \mu(D_r), \quad \sigma > 0, \quad \alpha > 0, \quad h(z) \text{ is harmonic function in } C, \quad \text{for which}
\]
\[
    \int_1^{+\infty} e^{-\sigma \alpha^r} \int \pi \pi h(re^{i\phi}) d\phi dr < +\infty.
\]
Then \( u \in \text{SH}_{\alpha, \sigma}(C) \) when \( \forall \sigma' > \frac{1}{e\alpha} + \sigma e^\alpha \).

Proof.
Let \( V_p(z) = \int C_A_p(z, \zeta) d\mu(\zeta) \). Then \( u(z) = h(z) + V_p(z) \).

It is obvious that \( h(z) \) belongs to the class under consideration. We will show that \( V_p(z) \) also included in the class \( \text{SH}_{\alpha, \sigma}(C) \) for \( \forall \sigma' = \sigma'(\alpha) > \sigma \).

We apply the estimate (see [1], p. 94):
\[
    \ln |A_p(z, \zeta)| \leq \left| \frac{z}{\zeta} \right|^{p|k|}, \quad \zeta \neq 0, \quad z, \zeta \in C.
\]  
(4)

Let's get that:
\[
    u(z) \leq \int \left| \frac{z}{\zeta} \right|^{p|k|} d\mu(\zeta).
\]

To continue the evaluation of the function, we can partition the complex plane into sets:
\[
    \Delta_k = \left\{ z \in C : 2^k < |z| \leq 2^{k+1} \right\}, \quad \Delta_0 = \left\{ z \in C : |z| \leq 1 \right\}. \quad \text{Then} \quad u(z) \leq \sum_{k=0}^{+\infty} \int_{\Delta_k} \left| \frac{z}{\zeta} \right|^{p|k|} d\mu(\zeta).
\]

Each of the rings \( \Delta_k \) is divided into small rings and we use Lemma 2.

Let \( \delta_{k,j} = \left\{ z \in C : 2^k + j2^{-\alpha k} < |z| \leq 2^k + (j+1)2^{-\alpha k} \right\} \), \( 0 \leq j \leq \left[ \frac{2^{(\alpha+1)k}}{2} \right] \), where \( \left[ a \right] \) is the integer part of the number \( a \).

Then \( \Delta_k \subset \bigcup_{j=0}^{N_a} \delta_{k,j} \), where \( N_a = \left[ \frac{2^{(\alpha+1)k}}{2} \right] \).

Therefore,
\[
    \int_{\Delta_k} \left| \frac{z}{\zeta} \right|^{p|k|} d\mu(\zeta) \leq \sum_{j=0}^{N_a} \int_{\delta_{k,j}} \left| \frac{z}{\zeta} \right|^{p|k|} d\mu(\zeta).
\]

By Lemma 2, we obtain
\[
    \int_{\delta_{k,j}} \left| \frac{z}{\zeta} \right|^{p|k|} d\mu(\zeta) \leq \left| \frac{z}{\zeta} \right|^{p|k|} d\mu(\delta_{k,j}) \leq \left| \frac{z}{\zeta} \right|^{p|k|} n(2^k + (j+1)2^{-\alpha k}), \quad \zeta^* \text{ is a point of } \delta_{k,j}.
\]

It is obvious that
\[
    \left| \frac{z}{\zeta} \right|^{p|k|} n(2^k + (j+1)2^{-\alpha k}) \leq C_0 \int_{2^k + (j+1)2^{-\alpha k}}^{2^k + j2^{-\alpha k}} \left| \frac{z}{t} \right|^{p|k|} n(t) dt, \quad k = 0, 1, \ldots
\]

Therefore
\[
    \int_{\Delta_k} \left| \frac{z}{\zeta} \right|^{p|k|} d\mu(\zeta) \leq C_0 \sum_{j=0}^{N_a} \int_{\delta_{k,j}} \left| \frac{z}{t} \right|^{p|k|} n(t) dt \leq C \int_{2^k}^{2^{k+1}} \left| \frac{z}{t} \right|^{p|k|} n(t) dt.
\]

Summing over \( k \), we get:
Let us estimate the last integral. According to (5) we have that
\[
\int_{-\pi}^{\pi} e^{-\sigma i^\alpha} \int_{-\pi}^{\pi} u^+(re^{i\theta}) \, d\phi \, dr \leq C \int_{1}^{\infty} e^{-\sigma i^\alpha} \int_{1}^{\infty} \left( \frac{r}{t} \right)^{p(t)} n(t) \, dt \, dr.
\]
Having established the convergence of the last integral, we prove the Lemma.
To do this, imagine the inner integral as a sum:
\[
\left( \int_{1}^{\infty} \left( \frac{r}{t} \right)^{p(t)} n(t) \, dt \right) \left( \int_{1}^{\infty} \left( \frac{r}{t} \right)^{p(t)} n(t) \, dt \right) = I_1 + I_2.
\]
Let us prove the boundedness of the second integral by a constant, independently of \( r \). Indeed,
\[
\left( \int_{1}^{\infty} \left( \frac{r}{t} \right)^{p(t)} n(t) \, dt \right) \left( \int_{1}^{\infty} \left( \frac{r}{t} \right)^{p(t)} n(t) \, dt \right) = \exp \left( \int_{1}^{\infty} \left( \frac{r}{t} \right)^{p(t)} n(t) \, dt \right).
\]
Consider the estimate for the integral \( I_2 \) we get that
\[
\left( \int_{1}^{\infty} \left( \frac{r}{t} \right)^{p(t)} n(t) \, dt \right) \left( \int_{1}^{\infty} \left( \frac{r}{t} \right)^{p(t)} n(t) \, dt \right) \leq C \int_{1}^{\infty} n(t) e^{-\sigma i^\alpha} \, dt < C \int_{1}^{\infty} n(t) e^{-\sigma i^\alpha} \, dt < +\infty.
\]
We estimate the integral.
\[
I_1 = \int_{1}^{\infty} \left( \frac{r}{t} \right)^{p(t)} n(t) \, dt.
\]
To calculate the largest value of the function \( p(t)(\ln r - \ln t) \) on an interval \([1;e^r]\) we put \( x = \ln r \) and \( \gamma(x,t) = p(t)(x - \ln t) \).
\[
\gamma'(x,t) = p'(t)(x - \ln t) - \frac{p(t)}{t} = \sigma \alpha^{-1} - \sigma \alpha^{-1} = \sigma \alpha^{-1} \left( x - \ln \left( \frac{1}{te^\alpha} \right) \right) = 0.
\]
That is \( \ln r = \ln \left( \frac{1}{te^\alpha} \right), t = re^{-\alpha}, \alpha = r^\alpha e^{-1} \). This point is the maximum point, therefore
\[
\gamma(x,t) = \gamma \left( x, e^{-\frac{1}{\alpha}} \right) = p \left( e^{-\frac{1}{\alpha}} \right) \left( \ln r - \ln \left( e^{-\frac{1}{\alpha}} \right) \right).
\]
Because \( \max \left( \frac{r}{t} \right)^{p(t)} \leq \left( \frac{r}{re^{-\alpha}} \right)^{e^\alpha} \), then
Okhlupina O.V.  
Description of some Weighted Exponential Classes of Subharmonic Functions

Вестник ЮУрГУ. Серия «Математика. Механика. Физика»
2018, том 10, № 1, С. 5–11

\[ \int n(t) \left( \frac{r(t)}{t} \right)^{\sigma r} \frac{dt}{t} \leq \int n(t) \left( \frac{1}{e^{\alpha \sigma}} \right) \frac{dt}{t} = \int n(t) e^{\sigma t} dt = \int n(t) e^{\sigma t} \frac{dt}{t} \]

\[ \int e^{-\sigma t} e^{\sigma t} \frac{dt}{t} = \int e^{-\sigma t} \frac{dt}{t} = \int e^{\sigma t} \frac{dt}{t} = C_1 \int n(t) dt \cdot e^{\sigma t} \]

In view of Lemma 1, we write that \[ \int n(t) dt \leq C e^{\sigma t} \alpha \]

Using the last estimate, we clarify the values \( \sigma' \), that ensure the convergence of the integral:

\[ \int_{1}^{\infty} e^{-\sigma t} e^{\sigma t} \frac{dt}{t} \leq \sigma r - \sigma(e^t) \alpha = 0, \ r^\alpha \left( \sigma' - \sigma e^\alpha - 1 \right) > 0, \ \sigma' > \frac{1}{\alpha e} \]

The lemma is proved.

Let us prove the auxiliary theorem 2.

**Theorem 2.** Let \( u \) is an arbitrary subharmonic function in the class \( \text{SH}_{\sigma, \alpha}(C) \), \( \mu(\zeta) \) is an arbitrary measure of the function \( u \), in this case \( \mu(D_t) = n(t), 0 < t < +\infty \). Then

\[ \int_{1}^{\infty} n(t) e^{-\sigma t} \frac{dt}{t} < +\infty \]

**Proof.** We integrate the integral by parts. Using the equality of Jensen for subharmonic functions (see [1]), it is enough to estimate the integral:

\[ I = \int_{1}^{\infty} \left( \int_{1}^{\infty} n(r) \frac{dr}{r} \right) e^{-\sigma \alpha} dt \]

We integrate \( I \) by parts:

\[ I = -\frac{1}{\alpha \sigma} \left( e^{-\sigma \alpha} \int_{1}^{\infty} n(r) \frac{dr}{r} \right) \left[ \frac{1}{t^\alpha} \left( \int_{1}^{\infty} n(r) \frac{dr}{r} \right) + n(t) \right] dt \]

According to Lemma 1, we have:

\[ I = \int_{1}^{\infty} e^{-\sigma \alpha} \left( \frac{1}{t^\alpha} \int_{1}^{\infty} n(r) \frac{dr}{r} + n(t) \right) dt = \int_{1}^{\infty} e^{-\sigma \alpha} \left( \frac{1}{t^\alpha} \int_{1}^{\infty} n(r) \frac{dr}{r} + n(t) \right) dt \]

By the hypothesis of the theorem \( I \leq C \).

It is clear that in \( 0 < \alpha < 1 \) the theorem is proved, since from the condition (5) implies that \[ \int_{1}^{\infty} t^{\alpha} n(t) dt < +\infty \]

Suppose \( \alpha > 1 \). Then by Lemma 1:

\[ \int_{1}^{\infty} e^{-\sigma t} \frac{dt}{t^\alpha} \leq C_1 \int_{1}^{\infty} e^{-\sigma t} \frac{dt}{t^\alpha} = C_1 \int_{1}^{\infty} \frac{dt}{t^{2\alpha-1}} < +\infty \]

Because \( \alpha > 1 \), then \[ \int_{1}^{\infty} e^{-\sigma t} \frac{dt}{t^\alpha} < +\infty \]

The theorem is proved.
The proof of the main result
The proof of the direct assertion of theorem 1 follows from theorem 2.
The validity of the converse follows from Lemma 3.
That proves theorem 1 completely.

From Theorem 1 directly follows

**Theorem 3.** Let $\alpha > 0$, $\text{SH}_{\alpha,\infty} = \bigcup_{\sigma > 0} \text{SH}_{\alpha,\sigma}$. Then class $\text{SH}_{\alpha,\infty}$ coincides with the class of subharmonic functions in $C$, representable in the form $u(z) = \int_C \ln|A_p(z,\xi)|d\mu(\xi) + h(z)$, where $\mu$ is non-negative measure in $C$, such that $n(t) = \mu(D_t)$, $D_t = \{z: |z| < t\}$, and also satisfies the condition

$$\int_1^{+\infty} \frac{n(t)e^{-\sigma t}}{t^{\alpha}} dt < +\infty$$

for some $\alpha \geq 0$, $h$ an arbitrary harmonic function in $C$, for which there exists

$$\sigma > 0: \int_1^{+\infty} e^{-\sigma t} \int_{-\pi}^{\pi} |h(re^{i\theta})| dr d\theta < +\infty.$$

Опи́сание некото́рых ве́совых экспо́ненциа́льных клас́сов субга́рмони́ческих функци́й

О.В. Охлупи́на
Бря́нский госу́дарственны́й инже́нери́но-техно́логи́ческий університе́т, г. Бря́нск, Росси́йская Федера́ция
E-mail: helga131081@yandex.ru

Роль субгармонических функций в таких разделах анализа, как комплексный и вещественный анализ, весьма существенна. Такие классы функций тесно связаны с аналитическими гармоническими функциями и вносят важный вклад в общую теорию потенциала и математическую физику. В трудах Р. Неванлинны, У. Хеймана получены параметрические представления классов субгармонических в плоскости функций, характеристика которых имеет степенной рост в бесконечности. Вопрос о том, верны ли аналогичные представления для весовых классов, которые допускают более сильный рост в бесконечности (например, экспоненциальный рост), возникает в теории целых и мерomorphic функций. В статье введены в рассмотрение классы субгармонических функций с характеристикой Неванлинны, которая суммируется с экспоненциальным весом на комплексной плоскости, а также изучены представляющие меры функций таких классов. При доказательстве результатов применяются методы комплексного и функционального анализа. Существенную роль в исследовании играют потенциалы, построенные на основе факторов модифицированного произведения Вейерштрасса. Доказательство основного результата базируется на использовании вспомогательных утверждений, сформулированных в виде лемм.

Ключевые слова: субгармоническая функция; гармоническая функция; представляющие меры; характеристика Неванлинны.
