CONVERGENCE OF A MASS CONSERVING ALLEN-CAHN EQUATION
WHOSE LAGRANGE MULTIPLIER IS NONLOCAL AND LOCAL

MATTHIEU ALFARO AND PIERRE ALIFRANGIS

ABSTRACT. We consider the mass conserving Allen-Cahn equation proposed in [8]: the Lagrange multiplier which ensures the conservation of the mass contains not only nonlocal but also local effects (in contrast with [14]). As a parameter related to the thickness of a diffuse internal layer tends to zero, we perform formal asymptotic expansions of the solutions. Then, equipped with these approximate solutions, we rigorously prove the convergence to the volume preserving mean curvature flow, under the assumption that classical solutions of the latter exist. This requires a precise analysis of the error between the actual and the approximate Lagrange multipliers.

1. INTRODUCTION

Setting of the problem. In this paper, we consider $u_\varepsilon = u_\varepsilon(x,t)$ the solutions of an Allen-Cahn equation with conservation of the mass proposed in [8], namely

$$\partial_t u_\varepsilon = \Delta u_\varepsilon + \frac{1}{\varepsilon^2} \left( f(u_\varepsilon) - \frac{\int_\Omega f(u_\varepsilon)}{\int_\Omega \sqrt{4W(u_\varepsilon)}} \sqrt{4W(u_\varepsilon)} \right)$$

in $\Omega \times (0, \infty)$,

supplemented with the homogeneous Neumann boundary conditions

$$\frac{\partial u_\varepsilon}{\partial \nu}(x,t) = 0 \text{ on } \partial \Omega \times (0, \infty),$$

and the initial conditions

$$u_\varepsilon(x,0) = g_\varepsilon(x) \text{ in } \Omega.$$

Here $\Omega$ is a smooth bounded domain in $\mathbb{R}^N$ ($N \geq 2$) and $\nu$ is the Euclidian unit normal vector exterior to $\partial \Omega$. The small parameter $\varepsilon > 0$ is related to the thickness of a diffuse interfacial layer. The term

$$- \frac{\int_\Omega f(u_\varepsilon(x,t))}{\int_\Omega \sqrt{4W(u_\varepsilon(x,t))}} \sqrt{4W(u_\varepsilon(x,t))}$$

can be understood as a Lagrange multiplier for the mass constraint

$$\frac{d}{dt} \int_\Omega u_\varepsilon(x,t) \, dx = 0.$$

Let us notice that (1.4) combines nonlocal and local effects (see below).

The nonlinearity is given by $f(u) := -W''(u)$, where $W(u)$ is a double-well potential with equal well-depth, taking its global minimum value at $u = \pm 1$. More precisely we assume that $f$ is $C^2$ and has exactly three zeros $-1 < 0 < +1$ such that

$$f'(\pm 1) < 0, \quad f'(0) > 0 \quad \text{(bistable nonlinearity)},$$

and that \( f \) is odd, which implies in turn that
\[
\int_{-1}^{+1} f(u) \, du = 0 \quad \text{(balanced nonlinearity)}.
\]
The condition (1.6) implies that the potential \( W(u) \) attains its local minima at \( u = \pm 1 \), and (1.7) implies that \( W(-1) = W(+1) \). In other words, the two stable zeros of \( f \), namely \( \pm 1 \), have "balanced" stability. For the sake of clarity, in the sequel we restrict ourselves to the case where
\[
f(u) = u(1 - u^2), \quad W(u) = \frac{1}{4}(1 - u^2)^2.
\]
This will slightly simplify the presentation of the asymptotic expansions in Section 4 and is enough to capture all the features of the problem.

The initial data \( g_\varepsilon \) are well-prepared in the sense that they already have sharp transition layers whose profile depends on \( \varepsilon \). The precise assumptions on \( g_\varepsilon \) will appear in Theorem 2.3. For the moment, it is enough to note that
\[
\lim_{\varepsilon \to 0} g_\varepsilon = \begin{cases} 
-1 & \text{in the region enclosed by } \Gamma_0 \\
+1 & \text{in the region enclosed between } \partial \Omega \text{ and } \Gamma_0,
\end{cases}
\]
where \( \Gamma_0 \subset \subset \Omega \) is a given smooth bounded hypersurface without boundary.

Our goal is to investigate the behavior of the solutions \( u_\varepsilon \) of (1.1), (1.2), (1.3), as \( \varepsilon \to 0 \).

Related works and comments. It is long known that, even for not well-prepared initial data, the sharp interface limit of the Allen-Cahn equation
\[
\partial_t u_\varepsilon = \Delta u_\varepsilon + \varepsilon^{-2} f(u_\varepsilon)
\]
by its mean curvature. As long as the classical motion by mean curvature exists, it was proved in [12] and an optimal estimate of the thickness of the transition layers was provided in [2]. Let us also mention that, recently, the first term of the actual profile of the layers was identified [3]. If the mean curvature flow develops singularities in finite time, then a generalized motion can be defined via level-set methods and viscosity solutions, [18] and [15]. In this framework, the convergence of the Allen-Cahn equation to generalized motion by mean curvature was proved by Evans, Soner and Souganidis [17] and a convergence rate was obtained in [1].

The above results rely on the construction of efficient sub- and super-solutions. Nevertheless, when comparison principle does not hold, a different method exists for well-prepared initial data. It was used e.g. by Mottoni and Schatzman [24] for the Allen-Cahn equation (without using the comparison principle!); Alikakos, Bates and Chen [4] for the convergence of the Cahn-Hilliard equation
\[
\partial_t u_\varepsilon + \Delta \left( \varepsilon \Delta u_\varepsilon + \frac{1}{\varepsilon} f(u_\varepsilon) \right) = 0,
\]
to the Hele-Shaw problem; Caginalp and Chen [10] for the phase field system... The idea is to first construct solutions \( u_{\varepsilon,k} \) of an approximate problem thanks to matched asymptotic expansions. Next, using the lower bound of a linearized operator around such constructed solutions, an estimate of the error \( \|u_\varepsilon - u_{\varepsilon,k}\|_{L_p} \) is obtained for some \( p \geq 2 \).

Using these technics, Chen, Hilhorst and Logak [14] considered the Allen-Cahn equation with conservation of the mass
\[
\partial_t u_\varepsilon = \Delta u_\varepsilon + \frac{1}{\varepsilon^2} \left( f(u_\varepsilon) - \frac{1}{|\Omega|} \int_{\Omega} f(u_\varepsilon) \right),
\]
proposed by [25] as a model for phase separation in binary mixture. They proved its convergence to the volume preserving mean curvature flow
\[
V_n = -\kappa + \frac{1}{|\Gamma_t|} \int_{\Gamma_t} \kappa \, dH^{n-1} \quad \text{on } \Gamma_t.
\]
Here $V_n$ denotes the velocity of each point of $\Gamma_t$ in the normal exterior direction and $\kappa$ the sum of the principal curvatures, i.e. $N - 1$ times the mean curvature. For related results, we also refer the reader to the works [9] (radial case, energy estimates) and [22] (case of a system).

In a recent work, Brassel and Bretin [8] proposed the mass conserving Allen-Cahn equation (1.1) as an approximation for mean curvature flow with conservation of the volume (1.12). According to their formal approach and numerical computations, it seems that “(1.1) has better volume preservation properties than (1.11)”. Let us notice that, as far as the local Allen-Cahn equation is concerned, such an improvement of the accuracy of phase field solutions, thanks to an adequate perturbation term, was already performed in [20] or in [11].

In the present paper we prove the convergence of (1.1) to (1.12). Observe that in (1.11) the conservation of the mass (1.5) is ensured by the Lagrange multiplier $-\frac{1}{\Omega} \int_\Omega f(u_\varepsilon)$ which is nonlocal, whereas in the considered equation (1.1) the Lagrange multiplier (1.4) combines nonlocal and local effects. On the one hand, this will make the outer expansions completely independent of the inner ones, and will cancel the $\varepsilon$ order terms of all expansions (see Section 4). On the other hand, this makes the proof of Theorem 2.3 much more delicate since further accurate estimates are needed (see subsection 6.1). In other words, in the study [14] of (1.11), it turns out that the nonlocal Lagrange multipliers “disappear” while estimating the error estimate $u_\varepsilon \sim u_{\varepsilon,k}$. This will not happen in our context and our key point will be the following. Roughly speaking, our estimates of subsection 6.1 will make appear an integral of the error on the limit hypersurface which must be compared with the $L^2$ norm of the error. If the former is small compared with the latter then the Gronwall’s lemma is enough. If, as expected, the error concentrates so that the former becomes large compared with the latter, then the situation is favorable: a “sign minus” intends at decreasing the $L^2$ norm of the error (see subsection 6.1 and Remark 6.2 for details).

To conclude let us mention the work of Golovaty [21], where a related equation with a nonlocal/local Lagrange multiplier is considered. The convergence to a weak (via viscosity solutions) volume preserving motion by mean curvature is proved via energy estimates. As mentioned before, our method is different and allows to capture a fine error estimate between the actual solutions and the constructed approximate solutions.

2. Statement of the results

The flow (1.12). Let us first recall a few interesting features of the averaged mean curvature flow (1.12). It is volume preserving, area shrinking and every Euclidian sphere is an equilibrium. The local in time well posedness in a classical framework is well understood (see Lemma 2.1 for a statement which is sufficient for our purpose). It is also known that local classical solutions with convex initial data turn out to be global. Additionally, there exist non-convex hypersurfaces (close to spheres) whose flow is global. For more details on the averaged mean curvature flow (1.12), we refer the reader to [19], [23], [16] and the references therein.

Lemma 2.1 (Volume preserving mean curvature flow). Let $\Omega_0 \subset \subset \Omega$ be a subdomain such that $\Gamma_0 := \partial \Omega_0$ is a smooth hypersurface without boundary. Then there is $T^{\text{max}} \in (0, \infty]$ such that the averaged mean curvature flow (1.12), starting from $\Gamma_0$, has a unique smooth solution $\cup_{0 \leq t < T^{\text{max}}} (\Gamma_t \times \{t\})$ such that $\Gamma_t \subset \subset \Omega$, for all $t \in [0, T^{\text{max}})$.

In the sequel, for $\Gamma_0$ as in (1.9), we fix $0 < T < T^{\text{max}}$ and work on $[0, T]$. We define

$$\Gamma := \cup_{0 \leq t \leq T} (\Gamma_t \times \{t\}),$$
and denote by $\Omega_t$ the region enclosed by $\Gamma_t$. Let us define the step function $\tilde{u} = \tilde{u}(x, t)$ by

$$
\tilde{u}(x, t) := \begin{cases} 
-1 & \text{in } \Omega_t \\
1 & \text{in } \Omega \setminus \overline{\Omega_t} 
\end{cases} \quad \text{for all } t \in [0, T],
$$

which represents the sharp interface limit of $u_\varepsilon$ as $\varepsilon \to 0$. Let $d$ be the signed distance function to $\Gamma$ defined by

$$
d(x, t) = \begin{cases} 
-\text{dist}(x, \Gamma_t) & \text{for } x \in \Omega_t \\
\text{dist}(x, \Gamma_t) & \text{for } x \in \Omega \setminus \overline{\Omega_t}.
\end{cases}
$$

**Main results.** We rewrite equation (1.1) as

$$\tag{2.3} \partial_t u_\varepsilon - \Delta u_\varepsilon - \frac{1}{\varepsilon^2} \left( f(u_\varepsilon) - \varepsilon \lambda_\varepsilon(t) \sqrt{4W(u_\varepsilon)} \right) = 0 \quad \text{in } \Omega \times (0, \infty),$$

by defining

$$
\varepsilon \lambda_\varepsilon(t) := \frac{\int_{\Omega} f(u_\varepsilon)}{\int_{\Omega} \sqrt{4W(u_\varepsilon)}} = \frac{\int_{\Omega} u_\varepsilon - u_\varepsilon^3}{\int_{\Omega} 1 - u_\varepsilon^2}.
$$

Our first main result consists in constructing accurate approximate solutions.

**Theorem 2.2 (Approximate solutions).** Let us fix an arbitrary integer $k > \max(N, 4)$. Then there exist $(u_{\varepsilon,k}(x, t), \lambda_{\varepsilon,k}(t))_{t \in [0, T]}$ such that

$$\tag{2.5} \partial_t u_{\varepsilon,k} - \Delta u_{\varepsilon,k} - \frac{1}{\varepsilon} \left( f(u_{\varepsilon,k}) - \varepsilon \lambda_{\varepsilon,k}(t) \sqrt{4W(u_{\varepsilon,k})} \right) = \delta_{\varepsilon,k} \quad \text{in } \Omega \times (0, T),$$

with

$$
\|\delta_{\varepsilon,k}\|_{L^\infty(\Omega \times (0, T))} = O(\varepsilon^k) \quad \text{as } \varepsilon \to 0,
$$

and

$$
\partial u_{\varepsilon,k} / \partial \nu(x, t) = 0 \quad \text{on } \partial \Omega \times (0, T),
$$

$$
\frac{d}{dt} \int_{\Omega} u_{\varepsilon,k}(x, t) \, dx = 0 \quad \text{for all } t \in (0, T).
$$

Observe that by integrating (2.5) over $\Omega$ and using (2.7) and (2.8), we see that

$$
\varepsilon \lambda_{\varepsilon,k}(t) = \frac{\int_{\Omega} f(u_{\varepsilon,k}) + O(\varepsilon^{k+2})}{\int_{\Omega} \sqrt{4W(u_{\varepsilon,k})}}.
$$

Then we prove the following estimate, in the $L^2$ norm, on the error between the approximate solutions $u_{\varepsilon,k}$ and the solutions $u_\varepsilon$.

**Theorem 2.3 (Error estimate).** Let us fix an arbitrary integer $k > \max(N, 4)$. Let $u_\varepsilon$ be the solution of (1.1), (1.2), (1.3) with the initial conditions satisfying (1.9) and

$$
g_\varepsilon(x) = u_{\varepsilon,k}(x, 0) + \phi_\varepsilon(x) \in [-1, 1], \quad \int_{\Omega} \phi_\varepsilon = 0, \quad \|\phi_\varepsilon\|_{L^2(\Omega)} = O(\varepsilon^{k+\frac{3}{2}}).
$$

Then, there is $C > 0$ such that, for $\varepsilon > 0$ small enough,

$$
\sup_{0 \leq t \leq T} \|u_\varepsilon(\cdot, t) - u_{\varepsilon,k}(\cdot, t)\|_{L^2(\Omega)} \leq C\varepsilon^{k-\frac{1}{2}}.
$$

Let us notice that, since $-1 \leq g_\varepsilon \leq 1$, it follows from the maximum principle that $-1 \leq u_\varepsilon \leq 1$. Also since $g_\varepsilon \neq 1$ and $g_\varepsilon \neq -1$, the conservation of the mass implies $u_\varepsilon \neq 1$ and $u_\varepsilon \neq -1$, which shows that the definition of $\varepsilon \lambda_\varepsilon(t)$ in (2.4) actually makes sense.

As it will be clear from our construction in Section 5, the approximate solutions satisfy

$$
\|u_{\varepsilon,k} - \tilde{u}\|_{L^\infty((x,t): |d(x,t)| \geq \sqrt{T})} = O(\varepsilon^{k+\frac{3}{2}}), \quad \text{as } \varepsilon \to 0,
$$

...
with $\tilde{u}$ the sharp interface limit defined in (2.1) via the volume preserving mean curvature flow (1.12) starting from $\Gamma_0$. We can therefore interpret Theorem 2.3 as a result of convergence of the mass conserving Allen-Cahn equation (1.1) to the volume preserving mean curvature flow (1.12):

$$\sup_{0 \leq t \leq T} \| u_\varepsilon(\cdot, t) - \tilde{u}(\cdot, t) \|_{L^2(\Omega)} = O(\varepsilon^{1/4}), \quad \text{as } \varepsilon \to 0.$$  

Organizational of the paper. The organization of this paper is as follows. In Section 3 we present the needed tools which are by now rather classical. In Section 4, we perform formal asymptotic expansions of the solutions $(u_\varepsilon(x, t), \lambda_\varepsilon(t))$. This will enable to construct the approximate solutions $(u_{\varepsilon,k}(x, t), \lambda_{\varepsilon,k}(t))$, and so to prove Theorem 2.2, in Section 5. Last we prove the error estimate of Theorem 2.3 in Section 6. In particular and as mentioned before, a precise understanding of the error between the actual and the approximate Lagrange multipliers will be necessary (see subsection 6.1).

Remark 2.4. Through the paper, the notation $\psi_\varepsilon = \sum_{i \geq 0} \varepsilon^i \psi_i$ represents asymptotic expansions as $\varepsilon \to 0$ and means that, for all integer $k$, $\psi_\varepsilon = \sum_{i=0}^k \varepsilon^i \psi_i + O(\varepsilon^{k+1})$.

3. Preliminaries

For the present work to be self-contained, we recall here a few properties which are classical in the works mentioned in the introduction, [25], [4], [24], [10], [11], [14], [22], and the references therein.

3.1. Some related linearized operators. We denote by $\theta_0(\rho) := \tanh(\sqrt{\varepsilon} \rho)$ the standing wave solution of

$$\begin{align*}
\theta_0'' + f(\theta_0) &= 0 & \text{on } \mathbb{R}, \\
\theta_0(-\infty) &= -1, & \theta_0(0) &= 0, & \theta_0(\infty) &= 1,
\end{align*}$$

which we expect to describe the transition layers of solutions $u_\varepsilon$ observed in the stretched variable. Note that, for all $m \in \mathbb{N}$,

$$D_{\rho}^m \left[ \theta_0(\rho) - (\pm 1) \right] = O(\varepsilon^{-\sqrt{N} |\rho|}) \quad \text{as } \rho \to \pm \infty.$$  

We then consider the one-dimensional underlying linearized operator around $\theta_0$, acting on functions depending on the variable $\rho$ by

$$L \psi := -u_{\rho \rho} - f'(\theta_0(\rho)) u.$$  

Lemma 3.1 (Solvability condition and decay at infinity). Let $A(\rho, s, t)$ be a smooth and bounded function on $\mathbb{R} \times U \times [0, T]$, with $U \subset \mathbb{R}^{N-1}$ a compact set. Then, for given $(s, t) \in U \times [0, T]$ the problem

$$\begin{align*}
L \psi := -\psi_{\rho \rho} - f'(\theta_0(\rho)) \psi &= A(\rho, s, t) & \text{on } \mathbb{R}, \\
\psi(0, s, t) &= 0, & \psi(\cdot, s, t) & \in L^\infty(\mathbb{R}),
\end{align*}$$

has a solution (which is then unique) if and only if

$$\int_{\mathbb{R}} A(\rho, s, t) \theta_0'(\rho) \, d\rho = 0. \quad (3.3)$$

Under the condition (3.3), assume moreover that there are real constants $A^{\pm}$ and an integer $i$ such that, for all integers $m$, $n$, $l$,

$$D_{\rho}^m D_{s}^n D_{t}^l [A(\rho, s, t) - A^{\pm}] = O(|\rho|^i e^{-\sqrt{N} |\rho|}) \quad \text{as } \rho \to \pm \infty,$$

uniformly in $(s, t) \in U \times [0, T]$. Then

$$D_{\rho}^m D_{s}^n D_{t}^l [\psi(\rho, s, t) - A^{\pm}] = O(|\rho|^i e^{-\sqrt{N} |\rho|}) \quad \text{as } \rho \to \pm \infty,$$

uniformly in $(s, t) \in U \times [0, T]$. 
Proof. The lemma is rather standard (see [4], [2] among others) and we only give an outline of the proof. Multiplying the equation by $\theta_0'$ and integrating it by parts, we easily see that the condition (3.3) is necessary. Conversely, suppose that this condition is satisfied. Then, since $\theta_0'$ is a bounded positive solution to the homogeneous equation $\psi_{pp} + f' (\theta_0 (p)) \psi = 0$, one can use the method of variation of constants to find the above solution $\psi$ explicitly:

$$\psi (p, s, t) = -\theta_0' (p) \int_0^p \left( \theta_0'^{-2} (\zeta) \int_\zeta^\infty A (\zeta, s, t) \theta_0' (\rho) \, d\zeta \right) \, d\zeta.$$  

Using this expression along with the estimates (3.4) and (3.1), one then proves (3.5). \hfill \Box

Note also, that after the construction of the approximate solutions $u_{\varepsilon, k}$, we shall need the estimate of the lower bound of the spectrum of a perturbation of the self-adjoint operator $-\Delta - \varepsilon^{-2} f' (u_{\varepsilon, k})$ proved in [13]. This will be stated in Section 6.

3.2. Geometrical preliminaries. The following geometrical preliminaries are borrowed from [14], to which we refer for more details and proofs.

Parametrization around $\Gamma$. As mentioned before, we call $\Gamma = \bigcup_{0 \leq t \leq T} (\Gamma_t \times \{t\})$ the smooth solution of the volume preserving mean curvature flow (1.12), starting from $\Gamma_0$; we also denote by $\Omega_t$ the region enclosed by $\Gamma_t$. Let $d$ be the signed distance function to $\Gamma$ defined by

$$d (x, t) = \begin{cases} -\text{dist}(x, \Gamma_t) & \text{for } x \in \Omega_t, \\ \text{dist}(x, \Gamma_t) & \text{for } x \in \Omega \setminus \Omega_t. \end{cases}$$

We remark that $d$ is smooth in a tubular neighborhood of $\Gamma$, say in

$$\mathcal{N}_{3\delta} (\Gamma_t) := \{ x \in \Omega : |d(x, t)| < 3\delta \},$$

for some $\delta > 0$. We choose a parametrization of $\Gamma_t$ by $X_0 (s, t)$, with $s \in U \subset \mathbb{R}^{N - 1}$. We denote by $n (s, t)$ the unit outer normal vector on $\partial \Omega_t = \Gamma_t$. For any $0 \leq t \leq T$, one can then define a diffeomorphism from $(-3\delta, 3\delta) \times U$ onto the tubular neighborhood $\mathcal{N}_{3\delta} (\Gamma_t)$ by

$$X (r, s, t) = X_0 (s, t) + r n (s, t) = x \in \mathcal{N}_{3\delta} (\Gamma_t),$$

whose inverse is denoted by $r = d(x, t)$, $s = S (x, t) := (S^1 (x, t), \ldots, S^{N-1} (x, t))$. Then $\nabla d$ is constant along the normal lines to $\Gamma_t$, and the projection $S (x, t)$ from $x$ on $\Gamma_t$ is given by $X_0 (S(x, t), t) = x - d(x, t) \nabla d (x, t)$. For $x = X_0 (s, t) \in \Gamma_t$ denote by $\kappa_i (s, t)$ the principal curvatures of $\Gamma_t$ at point $x$ and by $V (s, t) := (X_0)_{\Gamma_t} (s, t).n (s, t)$ the normal velocity of $\Gamma_t$ at point $x$. Then, one can see that

$$\kappa (s, t) := \sum_{i=1}^{N-1} \kappa_i (s, t) = \Delta d (X_0 (s, t), t),$$

$$b_1 (s, t) := - \sum_{i=1}^{N-1} \kappa_i^2 (s, t) = - (\nabla d. \nabla \Delta d) (X_0 (s, t), t),$$

$$V (s, t) := (X_0)_{\Gamma_t} (s, t).n (s, t) = - d_t (X (r, s, t), t).$$

In particular, $d_t (x, t)$ is independent of $r = d(x, t)$ in a small enough tubular neighborhood of $\Gamma_t$. Changing coordinates form $(x, t)$ to $(r, s, t)$, to any function $\phi (x, t)$ one can associate the function $\tilde{\phi} (r, s, t)$ by

$$\tilde{\phi} (r, s, t) = \phi (X_0 (s, t) + rn (s, t), t) \quad \text{or} \quad \phi (x, t) = \tilde{\phi} (d(x, t), S(x, t), t).$$
The stretched variable. In order to describe the sharp transition layers of the solutions \( u_{\varepsilon} \) around the limit interface, we now introduce a stretched variable. Let us consider a graph \( \Gamma_{t}^{*} \) of the form

$$\Gamma_{t}^{*} = \{ X(r, s, t) : r = \varepsilon h_{\varepsilon}(s, t), s \in U \},$$

which is expected to represent the 0 level set, at time \( t \), of the solutions \( u_{\varepsilon} \). We define the stretched variable \( \rho(x, t) \) as “the distance from \( x \) to \( \Gamma_{t}^{*} \) in the normal direction, divided by \( \varepsilon \)”, namely

$$\rho(x, t) := \frac{d(x, t) - \varepsilon h_{\varepsilon}(S(x, t), t)}{\varepsilon}.$$  

(3.10)

In the sequel, we use \( (\rho, s, t) \) as independent variables for the inner expansions. The link between the old and the new variable is

$$x = \hat{X}(\rho, s) := X(\varepsilon(\rho + h_{\varepsilon}(s, t)), s, t) = X_{0}(s, t) + \varepsilon(\rho + h_{\varepsilon}(s, t))n(s, t).$$

Changing coordinates form \( (x, t) \) to \( (\rho, s, t) \), to any function \( \psi(x, t) \) one can associate the function \( \hat{\psi}(\rho, s, t) \) by

$$\hat{\psi}(\rho, s, t) = \psi(X_{0}(s, t) + \varepsilon(\rho + h_{\varepsilon}(s, t))n(s, t), t),$$

(3.11)

or \( \psi(x, t) = \hat{\psi}(\frac{d(x, t) - \varepsilon h_{\varepsilon}(S(x, t), t)}{\varepsilon}, S(x, t), t) \). A computation then yields

$$\varepsilon^{2}(\partial_{t}\hat{\psi} - \Delta\hat{\psi}) = -\hat{\psi}_{\rho\rho} - \varepsilon(V + \Delta d)\hat{\psi}_{\rho}$$

(3.12)

$$+ \varepsilon^{2}[\partial_{t}^{\Gamma}\hat{\psi} - \Delta^{\Gamma}\hat{\psi} - (\partial_{t}^{\Gamma}h_{\varepsilon} - \Delta^{\Gamma}h_{\varepsilon})\hat{\psi}_{\rho}] + \varepsilon^{2}[2\nabla^{\Gamma}h_{\varepsilon}\nabla^{\Gamma}\hat{\psi}_{\rho} - \nabla^{\Gamma}h_{\varepsilon}(\partial_{\rho}\hat{\psi})^{2}].$$

where

$$\partial_{t}^{\Gamma} := \partial_{t} + \sum_{i=1}^{N-1} S_{i}^{t}\partial_{s_{i}}, \quad \nabla^{\Gamma} := \sum_{i=1}^{N-1} \nabla S_{i}^{t}\partial_{s_{i}}, \quad \Delta^{\Gamma} := \sum_{i,j=1}^{N-1} \Delta S_{i}^{t}\partial_{s_{i,j}} + \sum_{i,j=1}^{N-1} \nabla S_{i}^{t}\nabla S_{i}^{t}\partial_{s_{i,j}}.$$  

(3.13)

Here \( \Delta d \) is evaluated at \( (x, t) = (X_{0}(s, t) + \varepsilon(\rho + h_{\varepsilon}(s, t))n(s, t), t) \), so that (3.7) and (3.8) imply

$$\Delta d = \Delta d(X_{0}(s, t) + \varepsilon(\rho + h_{\varepsilon}(s, t))n(s, t), t) \approx \kappa(s, t) - \varepsilon(\rho + h_{\varepsilon}(s, t))b_{1}(s, t) - \sum_{i \geq 2} \varepsilon^{i}(\rho + h_{\varepsilon}(s, t))^{i}b_{i}(s, t),$$

where \( b_{i}(s, t) (i \geq 2) \) are some given functions only depending on \( \Gamma_{t} \).

Last, define

$$\varepsilon J^{\varepsilon}(\rho, s, t) := \partial X(\rho, s) / \partial (\rho, s)$$

the Jacobian of the transformation \( X \) so that, in particular, \( dx = \varepsilon J^{\varepsilon}(\rho, s) ds d\rho \). Then, for all \( \rho \in \mathbb{R}, s \in U \) and \( 0 \leq t \leq T \), we have

$$J^{\varepsilon}(\rho, s, t) = \prod_{i=1}^{N-1} [1 + \varepsilon(\rho + h_{\varepsilon}(s, t))\kappa_{i}(s, t)].$$  

(3.14)

4. Formal asymptotic expansions

In this section, we perform formal expansions for the solutions \( u_{\varepsilon}(x, t) \) of (2.3). We start by outer expansions to represent the solutions “far from the limit interface”, then make inner expansions to describe the sharp transition layers. Last, expansions of the nonlocal term \( \lambda_{\varepsilon}(t) \) are performed. In the meanwhile we shall also discover the expansions of the correction terms \( h_{\varepsilon}(s, t) \) defined in (3.10).  

We assume that the solutions \( u_{\varepsilon}(x, t) \) are of the form

$$u_{\varepsilon}(x, t) \approx u_{\varepsilon}^{+}(t) := \pm 1 + \varepsilon u_{1}^{\pm}(t) + \varepsilon^{2} u_{2}^{\pm}(t) + \cdots$$  

(outer expansions),
Let us also recall that we have chosen \((4.7)\)
and by the (complete) expansion at order \(\varepsilon h\) \((4.6)\)
all
We also require the matching conditions between outer and inner expansions, that is, for all \((s, t) \in U \times [0, T]\), we get \((4.8)\)
\[ u_i(\rho, s, t) = 0 \quad \text{(normalization conditions),} \]
for all \((s, t) \in U \times [0, T]\).

As far as the nonlocal term \(\lambda_\varepsilon(t)\) is concerned we assume the expansions \((4.5)\)
\[ \lambda_\varepsilon(t) \approx \lambda_0(t) + \varepsilon \lambda_1(t) + \varepsilon^2 \lambda_2(t) + \cdots \quad \text{(nonlocal term).} \]
Last, the distance correcting term \(h_\varepsilon(s, t)\) is assumed to be described by \((4.6)\)
\[ h_\varepsilon(s, t) \approx h_1(s, t) + \varepsilon^2 h_2(s, t) + \cdots \quad \text{(distance correction term),} \]
for all \((s, t) \in U \times [0, T]\).

In the following, by the (complete) expansion at order 1 we mean \((4.7)\)
\[ \{d(x, t), \lambda_0(t), u_1(\rho, s, t), u_1^\pm(t)\} \quad \text{(expansion at order 1),} \]
and by the (complete) expansion at order \(i \geq 2\) we mean \((4.7)\)
\[ \{h_{i-1}(s, t), \lambda_{i-1}(t), u_i(\rho, s, t), u_i^\pm(t)\} \quad \text{(expansion at order } i \geq 2). \]

Let us also recall that we have chosen
\[ f(u) = u(1 - u^2), \quad W(u) = \frac{1}{4}(1 - u^2)^2. \]

**4.1. Outer expansions.** By plugging the outer expansions \((4.1)\) and the expansion \((4.5)\)
into the nonlocal partial differential equation \((2.3)\), we get \((4.8)\)
\[ \varepsilon^2 (u_\varepsilon^\pm)'(t) = u_\varepsilon^\pm(t) - (u_\varepsilon^\pm(t))^3 - \varepsilon \lambda_\varepsilon(t)(1 - (u_\varepsilon^\pm(t))^2)^2. \]
Since \(u_\varepsilon^\pm(t) \approx \sum_{i \geq 0} \varepsilon^i u_i^\pm(t)\), where \(u_0^\pm(t) = \pm 1\), an elementary computation yields
\[ -\varepsilon \lambda_\varepsilon(t)(1 - (u_\varepsilon^\pm(t))^2)^2 \approx \sum_{i \geq 1} \left( \sum_{p+q=i, q \neq 0} \lambda_p(t) \sum_{k+l=q} u_i^\pm(t) u_i^\pm(t) \right) \varepsilon^{i+1}, \]
and
\[ (u_\varepsilon^\pm(t))^3 \approx \sum_{i \geq 0} \left( \sum_{p+q=i} u_i^\pm(t) \sum_{k+l=q} u_i^\pm(t) u_i^\pm(t) \right) \varepsilon^i. \]
Hence, collecting the \(\varepsilon\) terms in \((4.8)\), we discover \(0 = u_1^\pm(t) - 3 u_1^\pm(t)(u_0^\pm(t))^2\) so that \(u_1^\pm(t) \equiv 0\). Next, an induction easily shows that
\[ u_i^\pm(t) \equiv 0 \quad \text{for all } i \geq 1. \]
Therefore the outer expansions are already completely known and are trivial:
\[ u_i^\pm(t) \equiv \pm 1. \]
In other words, thanks to the adequate form of the Lagrange multiplier, the outer expansions are independent of the expansion of the nonlocal term. This is in contrast with the equation considered in [14].
4.2. Inner expansions. It follows from (3.12) that, in the new variables, equation (2.3) is recast as

\begin{equation}
\hat{u}_\varepsilon + \varepsilon \lambda \varepsilon(t) (1 - (\hat{u}_\varepsilon)^2) - \varepsilon (V + \Delta d) \hat{u}_\varepsilon + \varepsilon^2 [\hat{u}_\varepsilon - \Delta \varepsilon \hat{u}_\varepsilon - (\partial^2 V \lambda \varepsilon) \hat{u}_\varepsilon] + \varepsilon^2 [2 \nabla \varepsilon h \cdot \nabla \varepsilon \hat{u}_\varepsilon - |\nabla \varepsilon h|^2 \hat{u}_\varepsilon].
\end{equation}

The \( \varepsilon^0 \) terms. By collecting the \( \varepsilon^0 \) terms above and using the normalization and matching conditions (4.3), (4.4) we discover that \( u_0(\rho, s, t) = \theta_0(\rho) \), with \( \theta_0 \) the standing wave solution of

\begin{equation}
\begin{cases}
\theta_0'' + f(\theta_0) = 0 & \text{on } \mathbb{R}, \\
\theta_0(-\infty) = -1, \quad \theta_0(0) = 0, \quad \theta_0(\infty) = 1.
\end{cases}
\end{equation}

Formally, this solution represents the first approximation of the profile of the transition layers around the interface observed in the stretched coordinates. Note that since \( f(u) = u - u^3 \), one can even compute \( \theta_0(\rho) = \tanh\left(\frac{\rho}{\sqrt{2}}\right) \).

The \( \varepsilon^1 \) terms. Next, since \( \hat{u}_\varepsilon(\rho, s, t) \approx \sum_{i \geq 0} u_i(\rho, s, t) \varepsilon^i \), where \( u_0(\rho, s, t) = \theta_0(\rho) \), an elementary computation yields

\begin{equation}
\varepsilon \lambda \varepsilon(t) (1 - (\hat{u}_\varepsilon)^2(\rho, s, t)) \approx - \sum_{i \geq 0} \left( \sum_{p+q=i} \lambda_p \lambda_q \beta_q(\rho, s, t) \right) \varepsilon^{i+1},
\end{equation}

where

\[ \beta_q(\rho, s, t) = \begin{cases} 
\theta_0^2(\rho) - 1 & \text{if } q = 0 \\
\sum_{k+i=q} u_k(\rho, s, t) u_i(\rho, s, t) & \text{if } q \geq 1,
\end{cases} \]

and also

\begin{equation}
(\hat{u}_\varepsilon)^3(\rho, s, t) \approx \sum_{i \geq 0} \left( \sum_{p+q=i} u_p(\rho, s, t) \sum_{k+i=q} u_k(\rho, s, t) u_i(\rho, s, t) \right) \varepsilon^i.
\end{equation}

Hence, plugging the expansion (3.13) of \( \Delta d \) into (4.10) and collecting the \( \varepsilon \) terms, we discover

\begin{equation}
\mathcal{L} u_1 := -u_{1,\rho \rho} - f'(\theta_0(\rho)) u_1 = (V + \kappa)(s, t) \theta_0'(\rho) - (1 - \theta_0^2(\rho)) \lambda_0(t).
\end{equation}

For the above equation to be solvable (see Lemma 3.1 for details) it is necessary that, for all \((s, t) \in U \times [0, T] \),

\begin{equation*}
\int_{\mathbb{R}} \mathcal{L} u_1(\rho, s, t) \theta_0(\rho) \, d\rho = 0,
\end{equation*}

which in turn yields

\begin{equation}
V(s, t) = -\kappa(s, t) + \sigma \lambda_0(t), \quad \sigma \equiv \frac{\int_{\mathbb{R}} (1 - \theta_0^2) \theta_0'}{\int_{\mathbb{R}} \theta_0^2}.
\end{equation}

As seen in subsection 3.2 the above equation can be recast as

\begin{equation}
d(\rho, x, t) = \Delta \varepsilon(x, t) \sigma \lambda_0(t) \quad \text{for } x \in \Gamma_t.
\end{equation}

Now, in view of (4.11), we can write \( 0 = \int_{-\infty}^\infty (\theta_0'' - f(\theta_0)) \theta_0' = \int_{-\infty}^\infty (\theta_0'' - W'(\theta_0)) \theta_0' \) and find the relation \( 1 - \theta_0^2 = \sqrt{2} \theta_0' \), so that \( \sigma = \sqrt{2} \). Plugging this and (4.15) into (4.14) we see that \( \mathcal{L} u_1 = 0 \). Therefore, the normalization \( u_1(0, s, t) = 0 \) implies

\begin{equation}
u_1(\rho, s, t) \equiv 0.
\end{equation}

Again this is in contrast with the equation considered in [14].
The $\varepsilon^i$ terms ($i \geq 2$). Now, taking advantage of $u_0(\rho, s, t) = \theta_0(\rho)$ and of $u_1(\rho, s, t) \equiv 0$ we identify, for $i \geq 2$, the $\varepsilon^i$ terms in all terms appearing in (4.10). In the sequel we omit the arguments of most of the functions and, by convention, the sum $\sum_{j=0}^{i-1}$ is null if $b < a$.

Using (4.13) we see that the $\varepsilon^i$ term in $\hat{u}_{\varepsilon\rho\rho} + u_\varepsilon - (\hat{u}_\varepsilon)^3$ is

$$-\mathcal{L}u_\varepsilon - \theta_0 \sum_{k=2}^{i-2} u_k u_{i-k} - \sum_{p=2}^{i-2} u_p \sum_{k+i=p}^{i-2} u_k u_l \quad \text{(term 1)}.$$  

In view of (4.12), the $\varepsilon^i$ term in $\varepsilon \lambda_\varepsilon(t)(1 - (\hat{u}_\varepsilon)^2)$ is

$$\lambda_{i-1}(1 - \theta_0^2) - \sum_{p+q=i-1, q \neq 0}^{i-3} \lambda_p \sum_{k+i=q}^{i-2} u_k u_l \quad \text{(term 2)}.$$  

In order to deal with the term $-\varepsilon(V + \Delta d)\hat{u}_\varepsilon$, we first note that (3.13) and (4.6) yield the following expansion of the Laplacian

$$\Delta d \approx \kappa - \sum_{i \geq 1} (b_1 h_i + \delta_i) \varepsilon^i,$$

with

$$\delta_i = \delta_i(\rho, s, t) = \sum_{k=0}^{i} c_k(s, t) \rho^k$$

a polynomial function in $\rho$ of degree lower than $i$, whose coefficients $c_k(s, t)$ are themselves polynomial in $(h_1, \ldots, h_{i-1})$ which are part of the formal expansions at lower orders, and in $(\rho_1, \ldots, \rho_i)$ which are given functions. Among others, we have $\delta_1(\rho, s, t) = b_1(s, t)\rho$ and $\delta_2(\rho, s, t) = b_2(s, t)(\rho + h_1(s, t))^2$. Combining $u_{\varepsilon\rho} \approx \theta_0' + \varepsilon^2 u_{2\rho} + \cdots$ and (4.20), we next discover that the $\varepsilon^i$ term in $-\varepsilon(V + \Delta d)\hat{u}_\varepsilon$ is

$$b_1 h_{i-1} \theta_0' + \delta_{i-1} \theta_0' - (V + \kappa) u_{(i-1)p}$$

$$+ \sum_{p=1}^{i-3} (b_1 h_p + \delta_p) u_{(i-1-p)p} \quad \text{(term 3)}.$$  

We see that the $\varepsilon^i$ term in $\varepsilon^2(\partial_t^2 \hat{u}_\varepsilon - \Delta^t \hat{u}_\varepsilon - (\partial_t^t h_\varepsilon - \Delta^t h_\varepsilon)\hat{u}_\varepsilon)$ is given by

$$\hat{u}_{i-2} - (\partial_t^t - \Delta^t) h_{i-1} - \theta_0' - \sum_{p=1}^{i-3} (\partial_t^t - \Delta^t) h_p u_{(i-1-p)p} \quad \text{(term 4)}.$$  

Note that

$$\varepsilon^2(\nabla^t h_\varepsilon)^2 \approx \varepsilon^2(\nabla^t h_1)^2 + \sum_{i \geq 3} (2\nabla^t h_1, \nabla^t h_{i-1} + \eta_i) \varepsilon^i,$$

where

$$\eta_i = \eta_i(s, t) := \sum_{p+q=i-2, p \neq 0, q \neq 0} \nabla^t h_{p+1}(s, t). \nabla^t h_{q+1}(s, t)$$

depends only on the derivatives of $h_1, \ldots, h_{i-2}$. Combining this with $u_{\varepsilon\rho\rho} \approx \theta_0'' + \varepsilon^2 u_{2\rho} + \cdots$, we discover that the $\varepsilon^i$ term in $-\varepsilon^2(\nabla^t h_\varepsilon)^2 u_{\varepsilon\rho\rho}$ is

$$-\beta_{i}(\nabla^t h_1, \nabla^t h_{i-1}) \theta_0'' - (\nabla^t h_1)^2 u_{(i-2)\rho\rho} - \sum_{k=0}^{i-3} \alpha_k u_{k\rho\rho} \quad \text{(term 5)},$$

where $\alpha_k = \alpha_k(s, t)$ depends only on the derivatives of $h_1, \ldots, h_{i-2}$ and $\beta_2 = 0$, $\beta_i = 2$ if $i \geq 3$.

Last, since $\nabla^t u_{\varepsilon\rho} \approx \varepsilon^2(\nabla^t u_{2\rho}) + \cdots$, we see that the $\varepsilon^i$ term in $\varepsilon^2[2\nabla^t h_\varepsilon, \nabla^t u_{\varepsilon\rho}]$ is

$$2 \sum_{k=2}^{i-2} \nabla^t h_{i-1-k}, \nabla^t u_{k\rho} \quad \text{(term 6)}.$$
Lemma 4.1 where

\[ L u_i = (\mathcal{M}^T h_{i-1}) \theta_0' - (1 - \theta_0^2) \lambda_{i-1} + \beta_i (\nabla^T h_1, \nabla^T h_{i-1}) \theta_0'' + |\nabla^T h_1|^2 u_{i(2)p} + R_{i-1} \]

where \( \mathcal{M}^T \) denotes the linear operator acting on functions \( h(s, t) \) by

\[ \mathcal{M}^T h := \frac{\partial^2}{\partial s^2} h - \Delta^T h - b_1 h, \]

and where \( R_{i-1} = R_{i-1}(\rho, s, t) \) contains all the remaining terms. Since it is important that \( R_{i-1} \) does not "contain" \( h_{i-1} \), we have to leave \( |\nabla^T h_1|^2 u_{i(2)p} \) for the case \( i = 2 \), but with a slight abuse of notation we can "insert" \( |\nabla^T h_1|^2 u_{i(2)p} \) in \( R_{i-1} \) for \( i \geq 3 \). As an example, for \( i = 2 \) we see that

\[ R_1(\rho, s, t) = -\delta_1(\rho, s, t)\theta_0' + b_1(\rho, s, t)\theta_0''(\rho), \]

so that we infer that, for all integers \( m, n, l \),

\[ D^m D^l_\rho D^k_s D^i_t[R_1(\rho, s, t)] = \mathcal{O}(|\rho| e^{-\sqrt{2} |\rho|}) \quad \text{as} \quad \rho \to \pm \infty, \]

uniformly in \( (s, t) \). Now, for \( i \geq 3 \), we isolate the “worst terms”—which are the \( \delta_i \)’s—in \( R_{i-1} \) and write

\[ R_{i-1} = -\delta_{i-1}\theta_0' - \sum_{p=1}^{i-3} \delta_p u_{i(1-p)} + r_{i-1}, \]

where \( r_{i-1} = r_{i-1}(\rho, s, t) \) contains all the remaining terms.

Lemma 4.1 (Decay of \( R_{i-1} \)). Let \( i \geq 2 \). Assume that, for any \( 1 \leq k \leq i - 1 \), there holds that, for all integers \( m, n, l \),

\[ D^m D^l_\rho D^k_s D^i_t[u_k(\rho, s, t)] = \mathcal{O}(|\rho|^{k-1} e^{-\sqrt{2} |\rho|}) \quad \text{as} \quad \rho \to \pm \infty, \]

uniformly in \( (s, t) \in U \times [0, T] \). Then, for all integers \( m, n, l \)

\[ D^m D^l_\rho D^k_s D^i_t[R_{i-1}(\rho, s, t)] = \mathcal{O}(|\rho|^{i-3} e^{-\sqrt{2} |\rho|}) \quad \text{as} \quad \rho \to \pm \infty, \]

uniformly in \( (s, t) \in U \times [0, T] \).

Proof. Let us have a look at expression (4.30) of \( R_{i-1} \). By a tedious but straightforward examination we see that \( r_{i-1}(\rho, s, t) \) depends only on

- \( V(s, t), \kappa(s, t), b_1(s, t), ..., b_i(s, t) \) which are bounded given functions
- \( \lambda_0(t), ..., \lambda_{i-2}(t) \)
- \( h_1(s, t), ..., h_{i-2}(s, t) \) and their derivatives w.r.t. \( s \) and \( t \)
- \( u_0(\rho, s, t) = \theta(\rho), u_1(\rho, s, t) = 0, ..., u_{i-1}(\rho, s, t) \) and their derivatives w.r.t. \( \rho, s \) and \( t \)

in such a way that it is \( \mathcal{O}(|\rho|^{i-2} e^{-\sqrt{2} |\rho|}) \) as \( \rho \to \pm \infty \). Concerning the term

\[ -\delta_{i-1}(\rho, s, t)\theta_0' \sum_{p=1}^{i-3} \delta_p u_{i(1-p)} + r_{i-1}, \]

the fact that it behaves like (4.32) follows from (4.31) and the fact that \( \delta_p(\rho, s, t) \) grows like \( |\rho|^k \), as seen in (4.21). \( \square \)

Now, in virtue of Lemma 3.1, the solvability condition for equation (4.26) yields, for all \( (s, t) \),

\[ (\mathcal{M}^T h_{i-1})(s, t) \int_R \theta_0'^2 - \lambda_{i-1}(t) \int_R (1 - \theta_0^2) \theta_0' + \int_R R_{i-1}(\cdot, s, t) \theta_0' = 0. \]

Note that the term \( -\beta_i(\nabla^T h_1, \nabla^T h_{i-1}) \theta_0'' \) does not appear above since \( \int_R \theta_0'' \theta_0' = 0 \). Note also that the term \( -|\nabla^T h_1|^2 u_{i(2)p} \) does not appear for the same reason if \( i = 2 \).
and because it can be “hidden” in $R_{i-1}$ for $i \geq 3$ without altering the fact that $R_{i-1}$ does not depend on $h_{i-1}$. The above equality can be recast as

$$\mathcal{M}^T h_{i-1}(s, t) = \sigma h_{i-1}(t) - \sigma^* \int_R R_{i-1}(\rho, s, t) \theta_0 (\rho) \, d\rho,$$

with $\sigma$ defined in (4.15) and $\sigma^* := \left( \int_R \theta_0^2 (\rho) \right)^{-1}$. Note that, thanks to $1 - \theta_0^2 = \sqrt{2} \theta_0'$, we have $\sigma = \sqrt{2}$ (as seen before) and also $\sigma^* = \frac{1}{\sqrt{2}}$.

Let us have a look at $i = 2$. From (4.28) and the fact that $\int_R \rho \theta_0^2 (\rho) \, d\rho = 0$ (odd function), we see that (4.33) reduces to

$$\mathcal{M}^T h_1 (s, t) = \sigma h_1 (t).$$

Assume that $h_1$ satisfies the above equation. Then since $u_1 \equiv 0$ trivially satisfies (4.31), Lemma 4.1 implies that $R_1(\rho, s, t)$ together with its derivatives are $O(|\rho| e^{-\sqrt{2}|\rho|})$ as $\rho \to \pm \infty$. It follows from Lemma 3.1 that

$$\mathcal{L} u_2 = (\mathcal{M}^T h_1) \theta_0' - (1 - \theta_0^2) h_1 + \nabla^T h_1 \theta_0'' + R_1,$$

admits a unique solution $u_2(\rho, s, t)$ such that $u_2(0, s, t) = 0$, which additionally satisfies $D_{\rho}^n D_{\rho}^n D_t^1 [u_2(\rho, s, t)] = O(|\rho| e^{-\sqrt{2}|\rho|})$.

Now, an induction argument straightforwardly concludes the construction of the inner expansions.

**Lemma 4.2 (Construction by induction).** Let $i \geq 2$. Assume that, for all $1 \leq k \leq i - 1$ the term $u_k$ is constructed such that

$$D_{\rho}^n D_{\rho}^n D_t^1 [u_k(\rho, s, t)] = O(|\rho|^{k-1} e^{-\sqrt{2}|\rho|}) \quad \text{as} \quad \rho \to \pm \infty,$$

uniformly in $(s, t) \in U \times [0, T]$. Assume moreover that $h_{i-1}(s, t)$ satisfies the solvability condition (4.33). Then one can construct $u_i(\rho, s, t)$ solution of (4.26) such that $u_i(0, s, t) = 0$ and

$$D_{\rho}^n D_{\rho}^n D_t^1 [u_i(\rho, s, t)] = O(|\rho|^{i-1} e^{-\sqrt{2}|\rho|}) \quad \text{as} \quad \rho \to \pm \infty,$$

uniformly in $(s, t) \in U \times [0, T]$.

**Remark 4.3.** Note that the cancellation $u_1 \equiv 0$ implies that the term $u_i(\rho, s, t)$ appearing in the expansion of the solutions of (1.1) behaves like $O(|\rho|^{i-1} e^{-\sqrt{2}|\rho|})$, where the term $u_i(\rho, s, t)$ appearing in the expansion of the solutions of (1.11) behaves like $O(|\rho|^{i-1} e^{-\sqrt{2}|\rho|})$ (see [14]).

### 4.3. Expansions of the nonlocal term $\lambda_2 (t)$ and the distance correction term $h_2 (s, t)$.

By following [14, subsection 5.4] with $\sqrt{\varepsilon}$ playing the role of $\delta$, we see that an asymptotic expansion of the conservation of the mass (1.5) yields

$$0 = \frac{d}{dt} \int_{\Omega} u_2(x, t) \, dt \approx I_1 + I_2 + I_3,$$

where $I_1 = 0$, since in our case $u_2^+(t) \equiv \pm 1$, and

$$I_2 := \int_{|\rho| < 1/\sqrt{\varepsilon}} \partial_t^F \tilde{u}_c (\rho, s, t) \varepsilon J^F (\rho, s, t) \, d\rho \, ds,$$

$$I_3 := \int_{|\rho| < 1/\sqrt{\varepsilon}} (-V - \varepsilon \partial_t^F h_2 (s, t) \partial_\rho \tilde{u}_c (\rho, s, t) J^F (\rho, s, t) \, d\rho \, ds,$$

Combining $\partial_t^F := \partial_t + \sum_{i=1}^{N-1} S_i^\rho \partial_\rho$, with $u_0(\rho, s, t) = \theta_0 (\rho)$ and $u_1(\rho, s, t) \equiv 0$, we see that

$$\partial_t^F \tilde{u}_c (\rho, s, t) \approx \sum_{i \geq 2} \varepsilon^i [\partial_t + \sum_{k=1}^{N-1} S_i^k \partial_\rho] u_i (\rho, s, t).$$
In view of the above inner expansions, this implies
\[ \partial_t^\varepsilon u_\varepsilon (\rho, s, t) \approx \sum_{i \geq 2} \varepsilon^i O \left( |\rho|^{i-1} e^{-\sqrt{2}|\rho|} \right), \]
where \( O \left( |\rho|^{i-1} e^{-\sqrt{2}|\rho|} \right) \) depends only on expansions at orders \( \leq i - 1 \). By plugging this into (4.39), we get
\[ I_2 \approx \sum_{i \geq 3} \varepsilon^i \gamma_{i-2}, \]
where \( \gamma_{i-2} = \gamma_{i-2}(t) \) depends only on expansions at orders \( \leq i - 2 \).

We now turn to the term \( I_3 \). We expand
\[ ( -V - \varepsilon \partial_t^\varepsilon \rho \cdot \sigma \lambda_i ) (s, t) \approx dt \left( X_0(s, t), t \right) - \sum_{i \geq 1} \varepsilon^i \partial_t^\varepsilon \rho \cdot \sigma \lambda_i (s, t), \]
and
\[ \partial_t^\varepsilon \rho \cdot \sigma \lambda_i (s, t) \approx \theta_0'(\rho) + \sum_{i \geq 2} \varepsilon^i \partial_t^\varepsilon \rho \cdot \sigma \lambda_i (s, t). \]

Expanding the Jacobian (3.14) and using (3.7), we get
\[ J^\varepsilon (\rho, s, t) \approx 1 + \Delta d(X_0(s, t), t) \varepsilon (\rho + h^\varepsilon(s, t)) + \sum_{i \geq 2} \varepsilon^i \mu_{i-1}, \]
where \( \mu_{i-1} = \mu_{i-1}(\rho, s, t) \) depends only on expansions at orders \( \leq i - 1 \). Multiplying the three above equalities, we see that the integrand in \( I_3 \) expands as
\[ \theta_0' d_t + \varepsilon \theta_0' \left[ -\partial_t^\varepsilon \rho \cdot \sigma \lambda_1 + h_1 d_t \Delta d + \rho d_t \Delta d \right] + \sum_{i \geq 2} \varepsilon^i \theta_0' \left[ -\partial_t^\varepsilon \rho \cdot \sigma \lambda_i + h_i d_t \Delta d + v_{i-1} \right], \]
where \( v_{i-1} = v_{i-1}(\rho, s, t) \) depends only on expansions at orders \( \leq i - 1 \). We integrate this over \( s \in U \) and \( |\rho| < 1/\sqrt{\varepsilon} \) and, using \( \int_{|\rho| < 1/\sqrt{\varepsilon}} \theta_0'(\rho) d\rho = 2 \) and \( \int_{|\rho| < 1/\sqrt{\varepsilon}} \rho \theta_0'(\rho) d\rho = 0 \) (odd function), we discover
\[ \frac{1}{2} I_3 \approx \int_U d_t(s, t) \, ds + \varepsilon \int_U \left[ -\partial_t^\varepsilon \rho \cdot \sigma \lambda_1 + h_1 d_t \Delta d + \rho d_t \Delta d \right] \, ds \\
+ \sum_{i \geq 2} \varepsilon^i \int_U \left[ -\partial_t^\varepsilon \rho \cdot \sigma \lambda_i + h_i d_t \Delta d + v_{i-1} \right] \, ds, \]
where \( \omega_{i-1} = \omega_{i-1}(t) \) depends only on expansions at orders \( \leq i - 1 \). Using (4.16) to substitute \( d_t, (4.34) \) to substitute \( \partial_t^\varepsilon \rho \cdot \sigma \lambda_1, (4.33) \) to substitute \( \partial_t^\varepsilon \rho \cdot \sigma \lambda_i, \) we have
\[ \frac{1}{2} I_4 \approx \int_U \left( \Delta d - \sigma \lambda_0 \right) \, ds + \varepsilon \int_U \left[ -\Delta^\varepsilon h_1 - b_1 h_1 - \sigma \lambda_1 + (d_t \Delta d) h_1 \right] \, ds \\
+ \sum_{i \geq 2} \varepsilon^i \int_U \left[ -\Delta^\varepsilon h_i - b_i h_i - \sigma \lambda_i + (d_t \Delta d) h_i \right] \, ds + \zeta_{i-1} \]
where \( \zeta_{i-1} = \zeta_{i-1}(t) \) depends only on expansions at orders \( \leq i - 1 \).

Last, using \( \int_U \Delta^\varepsilon h_i \, ds = 0 \), we see that \( I_2 + I_3 \approx 0 \) reduces to
\[ \sigma \lambda_0(t) = \overline{\Delta d(\cdot, t)} \]
\[ \sigma \lambda_1(t) = - [b_1(\cdot, t) - d_t(\cdot, t) \overline{\Delta d(\cdot, t)}] h_1(\cdot, t) \]
\[ \sigma \lambda_i(t) = - [b_i(\cdot, t) - d_t(\cdot, t) \overline{\Delta d(\cdot, t)}] h_i(\cdot, t) + \Lambda_{i-1}(t) \quad (i \geq 2), \]
where \( \overline{\phi(\cdot)} := \frac{1}{|U|} \int_U \phi \) denotes the average of \( \phi \) over \( \Gamma_t \) (parametrized by \( U \)), and \( \Lambda_{i-1}(t) \) depends only on expansions at orders \( \leq i - 1 \). Moreover if we plug (4.41), (4.42) and
(4.33) into (4.16), (4.34) and (4.33), we have the following closed system for \( d, h_1, \ldots, h_i \) on \( U \times [0, T] \):

\[
\begin{align*}
(4.44) \quad d_t &= \Delta d - \Delta d(\cdot, t) \\
(4.45) \quad \partial_t^i h_1 &= \Delta^i h_1 + b_1 h_1 - [b_1(\cdot, t) - d_1(\cdot, t) \Delta d(\cdot, t)] h_1(\cdot, t) \\
(4.46) \quad \partial_t^i h_i &= \Delta^i h_i + b_1 h_i - [b_1(\cdot, t) - d_i(\cdot, t) \Delta d(\cdot, t)] h_i(\cdot, t) + \Lambda_{i-1}(t) \quad (i \geq 2).
\end{align*}
\]

5. THE APPROXIMATE SOLUTIONS \( u_{\varepsilon,k}, \lambda_{\varepsilon,k} \)

In order to construct our desired approximate solutions and prove Theorem 2.2, let us first explain how the previous section enables to determine, at any order, the outer expansion (4.1), the inner expansion (4.2), the expansion of the nonlocal term (4.5), and the expansion of the distance correction term (4.6).

First, as seen before, the outer expansion (4.1) is already completely known since \( u_{\varepsilon,k}^0(t) \equiv 0 \) for all \( i \geq 1 \).

Recall that \( \Gamma = \bigcup_{0 \leq t \leq T} (\Gamma_t \times \{t\}) \) denotes the unique smooth evolution of the volume preserving mean curvature flow (1.12) starting from \( \Gamma_0 \subset \subset \Omega \), to which we associate the signed distance function \( d(x, t) \). Hence, defining \( \lambda_0(t) \) as in (4.41) and \( u_1(\rho, s, \tau) \equiv 0 \) as in (4.17), we are equipped with the first order expansion

\[
\{ d(x, t), \lambda_0(t), u_1(\rho, s, \tau) \equiv 0 \}.
\]

Next, since \( \Gamma_t \) is a smooth hypersurface without boundary, there is a unique smooth solution \( h_1(s, t) \) to the parabolic equation (4.45). Assuming \( h_1(s, 0) \equiv 0 \) for \( s \in U \), we see that \( h_1(s, t) \equiv 0 \), which combined with (4.42) yields \( \lambda_1(t) \equiv 0 \). Notice that these cancellations are consistent with the observation of [8] that "(1.11) has better volume preserving properties than the traditional mass conserving Allen-Cahn equation (1.11)". In Section 4, we have defined \( u_2(\rho, s, t) \) as the solution of (4.35), which now reduces to \( L u_2 = -b_1(s, t) \rho \delta_0(\rho) \). This completes the second order expansion, namely

\[
\{ h_1(s, t) \equiv 0, \lambda_1(t) \equiv 0, u_2(\rho, s, t) \}.
\]

Now, for \( i \geq 2 \), let us assume that expansions \( \{ h_{k-1}(s, t), \lambda_{k-1}(t), u_k(\rho, s, t) \} \) are constructed for all \( 2 \leq k \leq i \). Therefore we can construct \( \Lambda_{i-1}(t) \) appearing in (4.46). Assuming \( h_1(s, 0) \equiv 0 \) for \( s \in U \), there is a unique smooth solution \( h_i(s, t) \) to the parabolic equation (4.46). This enables to construct \( \lambda_i(t) \) via (4.43). Now, \( h_i(s, t) \) satisfies the solvability condition (4.33) at rank \( i \), so that Lemma 4.2 provides \( u_{i+1}(\rho, s, t) \), the solution of (4.26) at rank \( i + 1 \) with \( u_{i+1}(0, s, t) = 0 \). This completes the construction of the \( i + 1 \)-th order expansion \( \{ h_i(s, t), \lambda_i(t), u_{i+1}(\rho, s, t) \} \).

Note also that, from the above induction argument, we also deduce the behavior (4.37) for all \( u_i(\rho, s, t) \)’s.

**Proof of Theorem 2.2.** We are now in the position to construct the approximate solutions as stated in Theorem 2.2. Let us fix an integer \( k > \max(N, 4) \). We define

\[
\begin{align*}
\rho_{\varepsilon,k}(x, t) &:= \frac{1}{\varepsilon} \left[ d(x, t) - \sum_{i=1}^{k+2} \varepsilon^i h_i(S(x, t), t) \right] = \frac{d_{\varepsilon,k}(x, t)}{\varepsilon}, \\
u_{\varepsilon,k}^{in}(x, t) &:= \theta_0(\rho_{\varepsilon,k}(x, t)) + \sum_{i=1}^{k+3} \varepsilon^i u_i(\rho_{\varepsilon,k}(x, t), S(x, t), t), \\
u_{\varepsilon,k}^{out}(x, t) &:= \bar{u}(x, t), \\
\lambda_{\varepsilon,k}(t) &:= \lambda_0(t) + \sum_{i=1}^{k+2} \varepsilon^i \lambda_i(t),
\end{align*}
\]
where \( \bar{u} \) is the sharp interface limit defined in (2.1). We introduce a smooth cut-off function \( \zeta(z) = \zeta_\varepsilon(z) \) such that

\[
\begin{align*}
\zeta(z) &= 1 & \text{if } |z| \leq \sqrt{\varepsilon}, \\
\zeta(z) &= 0 & \text{if } |z| \geq 2\sqrt{\varepsilon}, \\
0 &\leq z\zeta'(z) \leq 4 & \text{if } \sqrt{\varepsilon} \leq |z| \leq 2\sqrt{\varepsilon}.
\end{align*}
\]

For \( x \in \bar{\Omega} \) and \( 0 \leq t \leq T \), we define

\[
u^{\varepsilon,k}(x,t) = \zeta(d(x,t))u^{in}_{\varepsilon,k}(x,t) + [1 - \zeta(d(x,t))]u^{out}_{\varepsilon,k}(x,t).
\]

If \( \varepsilon > 0 \) is small enough then the signed distance \( d(x,t) \) is smooth in the tubular neighborhood \( \mathcal{N}_\varepsilon(\partial \Omega) \), and so is \( u^{in}_{\varepsilon,k}(x,t) \). This shows that \( u^{\varepsilon,k} \) is smooth.

Plugging \( (u^{\varepsilon,k}(x,t), \lambda_\varepsilon(t)) \) into the left hand side member of (2.5), we find an error term \( \delta_{\varepsilon,k}(x,t) \) which is such that

- \( \delta_{\varepsilon,k}(x,t) = 0 \) on \( \{|d(x,t)| \geq 2\sqrt{\varepsilon} \} \) since, then, \( u^{\varepsilon,k} = u^{out}_{\varepsilon,k} = \pm 1 \),
- \( \| \delta_{\varepsilon,k} \|_{L^\infty} = O(\varepsilon^{k+2}) \) on \( \{|d(x,t)| \leq \sqrt{\varepsilon} \} \) since, then, \( u^{\varepsilon,k} = u^{in}_{\varepsilon,k} \) and the expansions of Section 4 were done on this purpose,
- \( \| \delta_{\varepsilon,k} \|_{L^\infty} = O(\varepsilon^k) \), for any integer \( k^* \), on \( \{ \sqrt{\varepsilon} \leq |d(x,t)| \leq 2\sqrt{\varepsilon} \} \) since, then, the decaying estimates (3.1) and (4.37) imply that \( u^{\varepsilon,k} - u^{out}_{\varepsilon,k} = u^{in}_{\varepsilon,k} - 1 = O(\varepsilon^{-2k^*}) \), valid also after any differentiation.

Hence \( \| \delta_{\varepsilon,k} \|_{L^\infty(\Omega \times (0,T))} = O(\varepsilon^{k+2}) \), which is even better than (2.5). Also \( u^{\varepsilon,k} \) clearly satisfies (2.7).

Now, to ensure the conservation of the mass of the approximate solutions, we add a correcting term (which depends only on time) and define

\[
u_{\varepsilon,k}(x,t) = u^{\varepsilon,k}(x,t) + \frac{1}{|\Omega|} \int_{\Omega} (u^{\varepsilon,k}(x,0) - u^{\varepsilon,k}(x,t)) \, dx,
\]

which then satisfies (2.8), and still (2.7). Note also that subsection 4.3 implies that the correcting term

\[
\int_{\Omega} (u^{\varepsilon,k}(x,0) - u^{\varepsilon,k}(x,t)) \, dx = \int_{0}^{t} \int_{\Omega} \partial_t u^{\varepsilon,k}(x,\tau) \, d\tau \, dx
\]

is \( O(\varepsilon^{k+2}) \) together with its time derivative. Hence, when we plug \( u_{\varepsilon,k} = u^{\varepsilon,k} + O(\varepsilon^{k+2}) \) into the left hand side member of (2.5), we find an error term \( \delta_{\varepsilon,k} \) whose \( L^\infty \) norm is \( O(\varepsilon^k) \).

6. Error estimate

We shall here prove the error estimate, namely Theorem 2.3. For ease of notation, we drop most of the subscripts \( \varepsilon \) and write \( u, \lambda, u_k, \lambda_k, \delta_k \) for \( u_{\varepsilon}, \lambda_{\varepsilon}, u^{\varepsilon,k}, \lambda^{\varepsilon,k}, \delta_{\varepsilon,k} \) respectively. By \( \| \cdot \|, \| \cdot \|_{2+p} \) we always mean \( \| \cdot \|_{L^2(\Omega)}, \| \cdot \|_{L^{2+p}(\Omega)} \) respectively. In the sequel, we denote by \( C \) various positive constants which may change from places to places and are independent on \( \varepsilon > 0 \).

Let us define the error

\[
R(x,t) := u(x,t) - u_k(x,t).
\]

Clearly \( \| R \|_{L^\infty} \leq 3 \). It follows from the mass conservation properties (1.5), (2.8), and the initial conditions (2.10) that

\[
\int_{\Omega} R(x,t) \, dx = 0 \quad \text{for all } 0 \leq t \leq T, \quad \| R(\cdot,0) \| = O(\varepsilon^{-\frac{1}{2}}).
\]
We successively subtract the approximate equation (2.5) from equation (1.1), multiply by $R$ and then integrate over $\Omega$. This yields
\begin{equation}
\frac{1}{2} \frac{d}{dt} \int_{\Omega} R^2 = - \int_{\Omega} \nabla R^2 + \frac{1}{\varepsilon^2} \int_{\Omega} f'(u_k) R^2 + \frac{1}{\varepsilon^2} \int_{\Omega} (f(u) - f(u_k) - f'(u_k) R) R - \int_{\Omega} \delta_k R - \frac{1}{\varepsilon^2} \Lambda,
\end{equation}
where
\begin{equation}
\Lambda = \Lambda(t) := \int_{\Omega} [\varepsilon(1 - u^2) R - \varepsilon \lambda_k (1 - u_k^2) R].
\end{equation}
Since $(f(u) - f(u_k) - f'(u_k) R) R = -3u_k R^3 - R^4 = O(R^{2+p})$, where $p := \min(\frac{4}{3}, 1)$, we have
\begin{equation}
\left| \frac{1}{\varepsilon^2} \int_{\Omega} (f(u) - f(u_k) - f'(u_k) R) R \right| \leq \frac{1}{\varepsilon^2} C \| R \|_{2+p}^2 \leq \frac{1}{\varepsilon^2} C_1 \| R \|_p \| \nabla R \|_2^2,
\end{equation}
where we have used the interpolation result [14, Lemma 1]. We also have $\int_{\Omega} |\delta_k R| \leq \| \delta_k \|_\infty \| R \| = O(\varepsilon^k) \| R \|$, so that
\begin{equation}
\| R \| \frac{d}{dt} \| R \| \leq - \int_{\Omega} \nabla R^2 + \frac{1}{\varepsilon^2} \int_{\Omega} f'(u_k) R^2 + \frac{1}{\varepsilon^2} C_1 \| R \|_p \| \nabla R \|_2^2 + O(\varepsilon^k) \| R \| - \frac{1}{\varepsilon^2} \Lambda.
\end{equation}
We shall estimate $\Lambda$ in the following subsection. As mentioned before, this term is the main difference with the case of a strictly nonlocal Lagrange multiplier: its analogous for equation (1.11) is $(\varepsilon \lambda - \varepsilon \lambda_k) \int_{\Omega} R$ which vanishes, see [14].

Since $k > \max(N, 4)$ we have $k - \frac{1}{2} > \frac{4}{p} = \frac{4}{\min(\frac{4}{3}, 1)}$, so that the second estimate in (6.1) allows to define $t_\varepsilon > 0$ by
\begin{equation}
t_\varepsilon := \sup \left\{ t > 0, \forall 0 \leq \tau \leq t, \| R(\cdot, \tau) \| \leq (2C_1)^{-1/p} \varepsilon^{4/p} \right\}.
\end{equation}
We need to prove that $t_\varepsilon = T$ and that the estimate $O(\varepsilon^{4/p})$ is actually improved to $O(\varepsilon^{5-4})$. In the sequel we work on the time interval $[0, t_\varepsilon]$.

6.1. **Error estimates between the nonlocal/local Lagrange multipliers.** It follows from (2.9) that the term $\Lambda$ under consideration is recast as
\begin{equation}
\Lambda = \frac{A}{B} E - \frac{A_k}{B_k} E_k + \frac{O(\varepsilon^{k+2})}{B_k} E_k,
\end{equation}
where
\begin{align*}
A_k &= A_k(t) := \int_{\Omega} f(u_k), \\
B_k &= B_k(t) := \int_{\Omega} 1 - u_k^2, \\
E_k &= E_k(t) := \int_{\Omega} (1 - u_k^2) R, \\
\text{and A, B, E the same quantities with } u \text{ in place of } u_k.
\end{align*}

**Lemma 6.1** (Some expansions). We have, as $\varepsilon \to 0$,
\begin{equation}
A_k = \varepsilon^2 \alpha + O(\varepsilon^3), \quad B_k = \varepsilon \beta + O(\varepsilon^2),
\end{equation}
where
\begin{equation}
\alpha = \alpha(t) := \int_U \sum_{i=1}^{N-1} k_i(s, t) \int_{\mathbb{R}} \rho f(\theta_0(\rho)) \, d\rho, \quad \beta := 2\sqrt{2}|U|,
\end{equation}
and
\begin{equation}
E_k = O(\sqrt{2} \| R \|).
\end{equation}
Proof. We have seen in Section 5 that \( u_k = u_k^* + O(\varepsilon^{k+2}) \) so it is enough to deal with \( A_k^* \), \( B_k^* \) and \( E_k^* \). The lemma is then rather clear from the expansions of Section 4. We have
\[
A_k^* = \int_{|d(x,t)| \leq 2\sqrt{\varepsilon}} f(u_k^*)(x,t) \, dx = \int_{|d(x,t)| \leq \sqrt{\varepsilon}} f(u_k^*)(x,t) \, dx + O(e^{-\frac{\varepsilon}{2\sqrt{\varepsilon}}})
\]
\[
= \int_U \int_{|\rho| \leq 1/\sqrt{\varepsilon}} f(\theta_0(\rho) + O(\varepsilon^2)) \varepsilon J'(\rho, s, t) \, ds \, d\rho + O(e^{-\frac{\varepsilon}{2\sqrt{\varepsilon}}}).
\]

Using \( J'(\rho, s, t) = 1 + \varepsilon \rho \sum_{i=1}^{N-1} k_i(s, t) + O(\varepsilon^2) \) and \( \int_{|\rho| \leq 1/\sqrt{\varepsilon}} f(\theta_0(\rho)) \, d\rho = 0 \) (odd function), one obtains the estimate for \( A_k^* \). The estimate for \( B_k^* \) follows the same lines and is omitted. Last, the Hölder inequality yields \( |E_k| \leq (\int_{\Omega} (1 - u_k^2)^{1/2}) \cdot |R| = O(\sqrt{|R|}) \) since, again, \( dx = \varepsilon J'(\rho, s, t) \, ds \, d\rho \). \( \square \)

As a first consequence of the above lemma, it follows from (6.6) that
\[
\Lambda = \frac{A}{B} E - \frac{A_k}{B_k} E_k + O(\varepsilon^{k+3} |R|).
\]

Next, in view of the above lemma, \( u = u_k + R \) and \( |R| = O(\varepsilon^{4/p}) \), we can thus perform the following expansions
\[
A = A_k + \int_{\Omega} (1 - 3 u_k^2) R - 3 \int_{\Omega} u_k R^2 - \int_{\Omega} R^3
\]
\[
= A_k + 3E_k - 3 \int_{\Omega} u_k R^2 + O(\|R\|_{2+p}^4),
\]

since \( \int_{\Omega} R = 0 \),
\[
B^{-1} = B_k^{-1} \left( 1 - \frac{2 \int_{\Omega} u_k R}{B_k} - \left( \int_{\Omega} R^2 \right) \right)^{-1}
\]
\[
= B_k^{-1} \left( 1 + \frac{2 \int_{\Omega} u_k R}{B_k} + \left( \frac{2 \int_{\Omega} u_k R}{B_k} \right)^2 + O \left( \frac{\|R\|_{2+p}^3}{\varepsilon^3} \right) \right),
\]

and
\[
E = E_k - 2 \int_{\Omega} u_k R^2 + O(\|R\|_{2+p}^2).
\]

It follows that, using \( E_k = O(\sqrt{|R|}) \) and \( A_k = O(\varepsilon^2) \) (see Lemma 6.1),
\[
AE = A_k E_k - 2A_k \int_{\Omega} u_k R^2 + O(\varepsilon^2 \|R\|_{2+p}^2) + 3E_k^2 + O(\sqrt{|R|})
\]
\[
+ O(\sqrt{|R|} \|R\|_{2+p}^2) + O(\sqrt{|R|}) + O(\|R\|^4) + O(\|R\|_{2+p}^2) + O(\|R\|_{2+p}^4)
\]
\[
= A_k E_k - 3E_k^2 - 3E_k \int_{\Omega} u_k R^2 - 2A_k \int_{\Omega} u_k R^2 + O(\varepsilon^2 |R|_{2+p}^2) + O(\|R\|^3),
\]

since \( \|R\|_{2+p} = O(\|R\|^2) \). Then, using Lemma 6.1 and a methodical grading of the \( O \)'s (the typical used arguments being \( \|R\|_{2+p} = O(\|R\|^2) \) and, e.g., \( \|R\|^4 = O(\sqrt{|R|}) \) by the definition of \( t_k \), we arrive at
\[
\frac{A}{B} E = \frac{A_k}{B_k} E_k - B_k^{-1} \left[ 3E_k^2 - 3E_k \int_{\Omega} u_k R^2 + \frac{A_k}{B_k} E_k \int_{\Omega} 2u_k R \right]
\]
\[
- 2A_k \int_{\Omega} u_k R^2 + O(\varepsilon^2 \|R\|_{2+p}^2) + O(\|R\|^3),
\]
which in turn implies
\[
\frac{A}{B}E - \frac{A_k}{B_k}E_k = \frac{3E_k^2 - 3E_k \int_{\Omega} u_k R^2 + \frac{A_k}{B_k}E_k \int_{\Omega} 2u_k R}{B_k} \\
- \frac{A_k}{B_k} \int_{\Omega} 2u_k R^2 + \mathcal{O}(\|R\|_{L^p}^2) + \mathcal{O}(\varepsilon^{-1}\|R\|_3).
\]

Using Lemma 6.1 again, this implies
\[
(6.8) \quad \frac{A}{B}E - \frac{A_k}{B_k}E_k = \frac{3E_k^2 + \frac{A_k}{B_k}E_k \int_{\Omega} 2u_k R}{B_k} - \frac{A_k}{B_k} \int_{\Omega} 2u_k R^2 \\
+ \mathcal{O}(\varepsilon\|R\|_{L^p}^2) + \mathcal{O}(\varepsilon^{-1}\|R\|_3).
\]

The term \(-\frac{A_k}{B_k} \int_{\Omega} 2u_k R^2\) is harmless since it will be handled by the spectrum estimate Lemma 6.3. Let us analyze the fraction which is the worst term. For \(M > 1\) to be selected later, define \(\|R\|_\tau, \|R\|_{\tau^c}\), the \(L^2\) norms of \(R\) in the tube \(\mathcal{T} := \{(x, t) : |d(x, t)| \leq M\varepsilon\}, \) the complement of the tube respectively:
\[
\|R\|_\tau^2 := \int_{\{d(x, t) \leq M\varepsilon\}} R^2(x, t) \, dx, \quad \|R\|_{\tau^c}^2 := \int_{\{d(x, t) \geq M\varepsilon\}} R^2(x, t) \, dx.
\]

Observe that \(\mathcal{O}(\varepsilon)\) size of the tube allows to write
\[
\left| \int_{\tau} u_k R \right| \leq \left( \int_{\tau} u_k^2 \right)^{1/2} \left( \int_{\tau} R^2 \right)^{1/2} \leq C\sqrt{\varepsilon}\|R\|_\tau.
\]

Hence, using Lemma 6.1, cutting \(\int_{\tau} = \int_{\tau^c} + \int_{\tau^c}\), we get
\[
\left| \frac{A_k}{B_k}E_k \int_{\Omega} 2u_k R \right| \leq C\varepsilon|E_k|(\sqrt{\varepsilon}\|R\|_\tau + \|R\|_{\tau^c}) \\
\leq C\varepsilon|E_k|\|R\|_\tau + C\varepsilon^{2/5}E_k^2 + C\varepsilon^{8/5}\|R\|_{\tau^c}^2.
\]

As a result
\[
3E_k^2 + \frac{A_k}{B_k}E_k \int_{\Omega} 2u_k R \geq \frac{(3 - C\varepsilon^{2/5})E_k^2 - C\varepsilon\sqrt{\varepsilon}|E_k|\|R\|_\tau - C\varepsilon^{3/5}\|R\|_{\tau^c}^2}{B_k} \\
\geq \frac{E_k^2 - C\varepsilon\sqrt{\varepsilon}|E_k|\|R\|_\tau - C\varepsilon^{3/5}\|R\|_{\tau^c}^2}{B_k},
\]

for small \(\varepsilon > 0\). Now, observe that
\[
(6.10) \quad E_k^2 - C\varepsilon\sqrt{\varepsilon}|E_k|\|R\|_\tau \geq \begin{cases} 0 & \text{if } |E_k| \geq C\varepsilon\sqrt{\varepsilon}\|R\|_\tau \\
-C^2\varepsilon^3\|R\|_\tau^2 & \text{if } |E_k| \leq C\varepsilon\sqrt{\varepsilon}\|R\|_\tau.
\end{cases}
\]

**Remark 6.2.** The above inequality is the crucial one. One can interpret it as follows. Following [8, Proposition 2], we understand that \(E_k\) behaves like the integral on the hypersurface \(\Gamma_t\):
\[
\varepsilon \int_{d(x, t) = 0} R(x, t) \, d\sigma.
\]
If \(|E_k| = |\int_{\Omega} (1 - u_k) R|\) is large w.r.t. \(\mathcal{O}(\varepsilon\sqrt{\varepsilon}\|R\|_\tau)\) then \(E_k^2 - C\varepsilon\sqrt{\varepsilon}|E_k|\|R\|_\tau \geq 0\), which has the good sign to control the \(L^2\) norm of \(R\). In other words, if the error “intends” at concentrating on the hypersurface, the situation is quite favorable. On the other hand, if \(|E_k| = |\int_{\Omega} (1 - u_k^2) R|\) is small w.r.t. \(\mathcal{O}(\varepsilon\sqrt{\varepsilon}\|R\|_\tau)\) then we get the negative control \(-\mathcal{O}(\varepsilon^2\|R\|_{\tau^c}^2)\) (after dividing by \(B_k\)) which is enough for the Gronwall’s argument to work.
Putting together (6.7), (6.8), (6.9), (6.10) and $B_k = 2\sqrt{2}U|\varepsilon + O(\varepsilon^2)$, we arrive at

$$
\Lambda \geq - \frac{A_k}{B_k} \int_\Omega 2u_k R^2 - C\varepsilon^{3/5} ||R||_T^2 - C\varepsilon^2 ||R||_{\tau}^2
+ O(\varepsilon^{1 + \frac{2}{5}} ||R|| + O(\varepsilon ||R||^{2 + \frac{2}{5}}) + O(\varepsilon^{-1} ||R||^3).$$

(6.11)

6.2. Proof of Theorem 2.3. Equipped with the accurate estimate (6.11), we can now conclude the proof of the error estimate by following the lines of [14]. Combining (6.4) with (6.11) and using the interpolation inequality $||R||_{2 + p} \leq C||R||_p ||\nabla R||^2$, $||R||_T \leq ||R||$ and $||R|| = O(\varepsilon^2)$ (thanks to the definition of $t_\varepsilon$), we discover

$$
||R|| \frac{d}{dt} ||R|| \leq - \int_\Omega |\nabla R|^2 + \frac{1}{\varepsilon^2} \int_\Omega \left(f'(u_k) + \frac{A_k}{B_k} 2u_k \right) R^2
+ \frac{1}{\varepsilon^2} 2C_1 ||R||_T^p |\nabla R|^2 + \frac{1}{\varepsilon^2} C\varepsilon^{3/5} ||R||_T^2
+ C||R||^2 + O(\varepsilon^{-\frac{k}{2}}) ||R||
$$

Since $\varepsilon^2 \left( - \int_\Omega |\nabla R|^2 + \frac{1}{\varepsilon^2} \int_\Omega \left(f'(u_k) + \frac{A_k}{B_k} 2u_k \right) R^2 \right) \leq - \varepsilon^2 ||\nabla R||^2 + C ||R||^2$, we get

$$
||R|| \frac{d}{dt} ||R|| \leq (1 - \varepsilon^2) \left( - \int_\Omega |\nabla R|^2 + \frac{1}{\varepsilon^2} \int_\Omega \left(f'(u_k) + \frac{A_k}{B_k} 2u_k \right) R^2 \right)
- \varepsilon^2 ||\nabla R||^2 + \frac{1}{\varepsilon^2} 2C_1 ||R||_T^p |\nabla R|^2
+ \frac{1}{\varepsilon^2} C\varepsilon^{3/5} ||R||_T^2 + C||R||^2 + O(\varepsilon^{-\frac{k}{2}}) ||R||
$$

(6.12)

in view of the definition of $t_\varepsilon$ in (6.5). In the above inequality, let us write $\int_\Omega = \int_{\tau} + \int_{\tau'}$. In the complementary of the tube, observe that

$$
\int_{\tau'} \left(f'(u_k) + \frac{A_k}{B_k} 2u_k + C\varepsilon^{3/5} \right) R^2 = \int_{|d(x,t)| \geq M\varepsilon} \left(f'(u_k) + O(\varepsilon^{3/5}) \right) R^2,
$$

is nonpositive if $M > 0$ is large enough; this follows from the form of the constructed $u_k$ in Section 5 — roughly speaking we have $u_k(x,t) = \theta_0 \left( \frac{d(x,t)}{\varepsilon} + O(\varepsilon^2) \right) + O(\varepsilon^2)$ — $\theta_0(\pm \infty) = \pm 1$ and $f'(\pm 1) < 0$. As a result we collect

$$
||R|| \frac{d}{dt} ||R|| \leq (1 - \varepsilon^2) \left( - \int_{\tau} |\nabla R|^2 + \frac{1}{\varepsilon^2} \int_{\tau} \left(f'(u_k) + \frac{A_k}{B_k} 2u_k \right) R^2 \right)
+ C||R||^2 + O(\varepsilon^{-\frac{k}{2}}) ||R||
$$

(6.13)

In some sense, the problem now reduces to a local estimate since the linearized operator $-\Delta - \varepsilon^{-2} (f'(u_k) + \frac{A_k}{B_k} 2u_k)$ arises when studying the local unbalanced Allen-Cahn equation

$$
\partial_t u_\varepsilon = \Delta u_\varepsilon + \frac{1}{\varepsilon^2} \left( f(u_\varepsilon) - \frac{A_k}{B_k} (1 - u_\varepsilon^2) \right),
$$

whose singular limit is “mean curvature plus a forcing term” (see, among others, [2]). To conclude we need a spectrum estimate of the unbalanced linearized operator around the approximate solutions $u_\varepsilon$, namely $-\Delta - \varepsilon^{-2} (f'(u_k) + \frac{A_k}{B_k} 2u_k)$. This directly follows from the result of [13] for the balanced case. For related results on the spectrum of linearized operators for the Allen-Cahn equation or the Cahn-Hilliard equation, we also refer to [7], [5, 6, 24].
Lemma 6.3 (Spectrum of the unbalanced linearized operator around $u_k$ [13]). There is $C^* > 0$ such that
\[ - \int_T |\nabla R|^2 + \frac{1}{\varepsilon^2} \int_T \left( f'(u_k) + \frac{A_k}{B_k} 2 u_k \right) R^2 \leq C^* \int_T R^2, \]
for all $0 < t \leq T$, all $0 < \varepsilon \leq 1$, all $R \in H^1(\Omega)$.

Proof. Observe that
\[ u_k(x, t) = \begin{cases} \theta_0 \left( \frac{d_k(x, t)}{\varepsilon} \right) + O(\varepsilon^2) & \text{if } |d(x, t)| \leq \sqrt{\varepsilon} \\ \pm 1 + O(\varepsilon^{k+1}) & \text{if } |d(x, t)| \geq \sqrt{\varepsilon}, \end{cases} \]
Lemma 6.1 yields $\frac{A_k}{B_k} = \varepsilon^2 \cdot \frac{O(\varepsilon)}{d} + O(\varepsilon^2)$ so that we can write $f'(u_k) + \frac{A_k}{B_k} 2 u_k = f'(u_k')$, for some $u_k'$ such that
\[ u_k''(t) = \varepsilon^2 \frac{O(\varepsilon)}{d} - \varepsilon^2 \frac{O(\varepsilon)}{d^2} \theta_1 \left( \frac{d_k(x, t)}{\varepsilon} \right) + O(\varepsilon^2) \text{ if } |d(x, t)| \leq \sqrt{\varepsilon} \]
\[ \pm 1 + O(\varepsilon) \text{ if } |d(x, t)| \geq \sqrt{\varepsilon}, \]
where $\theta_1 \equiv 1$. In particular, $\int \cdots = \varepsilon^2 \frac{O(\varepsilon)}{d} f''(\theta_0) = \int \cdots f''(\theta_0) = 0$ (odd function) so that $u_k''$ has the correct shape for [13] to apply: see [4, shape (3.8) and proof of Theorem 5.1], [14, shape (16)] or [22, Section 4] for very related arguments. Details are omitted. □

Combining the above lemma and (6.13), we end up with
\[ \frac{d}{dt} \| R \| \leq C \| R \| + C \varepsilon^{k - \frac{1}{p}}. \]

The Gronwall’s lemma then implies that, for all $0 \leq t \leq t_\varepsilon$,
\[ \| R(\cdot, t) \| \leq (\| R(\cdot, 0) \| + \varepsilon^{k - \frac{1}{p}}) e^{C t_\varepsilon} = O(\varepsilon^{k - \frac{1}{p}}), \]

in view of (6.1). Since $k - \frac{1}{p} > \frac{1}{p}$, this shows that $t_\varepsilon = T$ and that the estimate $O(\varepsilon^{k/p})$ is actually improved to $O(\varepsilon^{k - \frac{1}{p}})$. This completes the proof of Theorem 2.3. □
