(Dated: August 30, 2017)

We introduce a new optimization procedure for Euclidean path integrals which compute wave functionals in conformal field theories (CFTs). We optimize the background metric in the space on which the path integration is performed. Equivalently this is interpreted as a position-dependent UV cutoff. For two-dimensional CFT vacua, we find the optimized metric is given by that of a hyperbolic space and we interpret this as a continuous limit of the conjectured relation between tensor networks and Anti–de Sitter (AdS)/conformal field theory (CFT) correspondence. We confirm our procedure for excited states, the thermofield double state, the Sachdev-Ye-Kitaev model and discuss its extension to higher-dimensional CFTs. We also show that when applied to reduced density matrices, it reproduces entanglement wedges and holographic entanglement entropy. We suggest that our optimization prescription is analogous to the estimation of computational complexity.

Recently, candidates on the basic mechanism of Anti–de Sitter (AdS)/conformal field theory (CFT) correspondence\textsuperscript{1} have been investigated actively. One prominent candidate is based on emergent spaces via tensor networks, such as MERA (multi-scale entanglement renormalization ansatz)\textsuperscript{2} as pioneered in\textsuperscript{3}; for recent developments refer to e.g.\textsuperscript{4–12}. The holographic computation of entanglement entropy\textsuperscript{13, 14} is naturally explained by this idea.

The purpose of this Letter is to reformulate this conjectured connection to tensor networks from the viewpoint of Euclidean path integrals. Indeed, the tensor network renormalization\textsuperscript{15} shows an Euclidean path integral description of a vacuum wave functional is well approximated by a MERA tensor network. In this approach, we first discretize the path integral into a lattice and rewrite it as a tensor network. Next the network is optimized by contracting the tensors and lattice sites are reduced, finally leading to the MERA network.

In our approach we would like to keep working in the Euclidean path integral description and perform the optimization by changing the structure (or geometry) of lattice regularization (refer to Fig.\textsuperscript{1}), which was first considered in\textsuperscript{12}, as explained in appendix\textsuperscript{.} In this Letter, we will present a systematic formulation of optimization by describing the change of regularization as that of the metric on the space where the path integral is done.

Our path integral approach has a number of advantages. Clearly, we can analyze any CFTs, including genuine holographic ones, while tensor network approaches provide toy models of holography. Also in tensor network descriptions there is a subtle issue that the MERA can also be interpreted as a de Sitter space\textsuperscript{3, 8}, while the refined tensor networks in\textsuperscript{8, 11} are argued to describe Euclidean hyperbolic spaces. In our Euclidean approach we can avoid this issue and we can directly show that the emergent space is a hyperbolic space.

The ground state wave functional in\textsuperscript{d}-dimensional CFTs on $R^d$ is computed by an Euclidean path integral:

$$
\Psi_{\text{CFT}}(\tilde{\phi}(x)) = \int \left( \prod_z \prod_{\epsilon<z<\infty} D\phi(z,x) \right) \epsilon^{-S_{\text{CFT}}(\phi)} \prod_x \delta(\phi(\epsilon,x)-\tilde{\phi}(x)),
$$

where the Euclidean time $\tau$ is related to $z$ via $z = -(\tau-\epsilon)$ and $x$ describes the other $d-1$-dimensional directions. We introduce a UV cutoff $\epsilon$ (i.e. the lattice constant) and consider a discretization of the above Euclidean path integral. The original flat space metric is given by

$$
ds^2 = \epsilon^{-2} \cdot (dz^2 + dx^i dx^i),
$$

and one cell of the regularized lattice has the unit area.

Now we would like to optimize this Euclidean path integral by changing the geometry of lattice regularization.

FIG. 1. A computation of ground state wave functional from Euclidean path integral and its optimization, which is described by a hyperbolic geometry. The right figure schematically shows its tensor network expression.
as in Fig. 1. The basic rule is that we should reproduce the correct vacuum wave functional (i.e. the one for the metric) even after the optimization up to a normalization factor i.e. \( \Psi_{\text{opt}} \propto \Psi_{\text{CFT}} \). The optimization can be done by modifying the background metric for the path integration as

\[
d s^2 = g_{zz}(z, x) d z^2 + g_{ij}(z, x) d x^i d x^j, \quad g_{zz}(z = \epsilon, x) = \epsilon^{-2}, \quad g_{ij}(z = \epsilon, x) = \delta_{ij} \cdot \epsilon^{-2}, \quad g_{L}(z = \epsilon, x) = 0,
\]

where the constraints argue that the UV regularization agrees with the original one (2) at \( z = \epsilon \) to reproduce the correct wave functional after the optimization.

Intuitively, our optimization corresponds to minimizing the number of lattice points, which is expected to measure the number of tensors (or complexity) in a tensor network. Note that we have in mind the procedure of tensor network renormalization [15], where a discretized path integral is mapped into a tensor network which consists of unitaries and isometries (refer also to the full paper [16]). It is not immediately clear what is the right path integral is mapped into a tensor network. Note that we have in mind the procedure of optimization as in Fig. 1. The basic rule is that we should reproduce the correct vacuum wave functional (i.e. the one for the metric) even after the optimization up to a normalization factor i.e. \( \Psi_{\text{opt}} \propto \Psi_{\text{CFT}} \). The optimization can be done by modifying the background metric for the path integration as

\[
d s^2 = g_{zz}(z, x) d z^2 + g_{ij}(z, x) d x^i d x^j, \quad g_{zz}(z = \epsilon, x) = \epsilon^{-2}, \quad g_{ij}(z = \epsilon, x) = \delta_{ij} \cdot \epsilon^{-2}, \quad g_{L}(z = \epsilon, x) = 0,
\]

where the constraints argue that the UV regularization agrees with the original one (2) at \( z = \epsilon \) to reproduce the correct wave functional after the optimization.

Before we go on, we would like to point out that the above optimization procedure can be generalized to excited states by inserting operators in the middle of path integration. Also, we can equally optimize nonconformal field theories if we assume a UV fixed point. For example, we can deform a CFT by adding a (time-independent) external field \( J(x) \). Then the optimization can be done by allowing a \( z \) dependence of the source \( J(z, x) \).

In two-dimensional CFTs, any metric is written as the diagonal form via a coordinate transformation

\[
d s^2 = e^{2\phi(z, x)} (d z^2 + d x^2), \quad e^{2\phi(z = \epsilon, x)} = \frac{1}{\epsilon^2}. \tag{4}
\]

The function \( \phi(z, x) \) describes the metric. With the universal UV cutoff \( \epsilon \), the measure of quantum fields \( \varphi \) in the CFT anomalously changes under Weyl rescaling [17]

\[
[D \varphi]_{g_{ab} = \epsilon^{2\phi} \delta_{ab}} = \epsilon^{S_L[\varphi] - S_L[0]} \cdot [D \varphi]_{g_{ab} = \delta_{ab}}, \tag{5}
\]

where \( S_L[\phi] \) is the Liouville action [18] (see also [17, 19]),

\[
S_L[\phi] = \frac{c}{24\pi} \int_{-\infty}^{\infty} d x \int_{\epsilon}^{\infty} d z [(\partial_x \phi)^2 + (\partial_z \phi)^2 + m e^{2\phi} + R_0 \phi], \tag{6}
\]

where \( R_0 \) is the Ricci scalar of the original space, which is zero in our setup here. The constant \( c \) is the central charge of two-dimensional CFT. The kinetic term in \( S_L \) describes the conformal anomaly and the potential term comes from UV regularization. In our treatment, \( \mu \) is an \( O(1) \) constant and we will simply set \( \mu = 1 \) by an appropriate shift of \( \phi \). For earlier relations between Liouville theory and three-dimensional gravity, refer to, e.g., [20], whose connections to our Letter are not obvious.

The ground-state wave functional \( \Psi_{g_{ab} = \epsilon^{2\phi} \delta_{ab}} \) computed from the path integral for the metric (3) is proportional to the one \( \Psi_{g_{ab} = \delta_{ab}} \) for the flat metric owing the conformal symmetry with the coefficient

\[
\Psi_{g_{ab} = \epsilon^{2\phi} \delta_{ab}}(\tilde{\varphi}(x)) = e^{S_L[\varphi] - S_L[0]} \cdot \Psi_{g_{ab} = \delta_{ab}}(\tilde{\varphi}(x)). \tag{7}
\]

Now we argue that the optimization is equivalent to minimizing the normalization \( e^{S_L[\varphi]} \) of the wave functional. The reason is that this factor measures the number of repetitions of the same operation (i.e. the path integral over a cell). In other words, the optimization chooses the most efficient Euclidean path integral.

Thus, the optimization can be completed by requiring the equation of motion of Liouville action \( S_L \)

\[
4 \partial_{ab} \partial_{ab} \phi = e^{2\phi}, \tag{8}
\]

where we introduced \( w = z + i x \) and \( \bar{w} = z - i x \). Its general solution is given by (see, e.g., [17, 21])

\[
e^{2\phi} = \frac{4 A'(w) B'(\bar{w})}{(1 - A(w) B(\bar{w}))^2}. \tag{9}
\]

Note that functions \( A(w) \) and \( B(\bar{w}) \) describe the degrees of freedom of conformal mappings.

First we choose the solution: \( A(w) = w, \quad B(\bar{w}) = -1/\bar{w} \). This leads to the Poincare metric \( H_2 \)

\[
e^{2\phi} = 4(w + \bar{w})^{-2} = z^{-2}. \tag{10}
\]

We argue that this is interpreted as the time slice of AdS3 dual to a holographic CFT. This is consistent with the tensor network description of AdS/CFT and can be regarded as its continuous version. Notice that we did not fix the overall normalization of the metric or equally the AdS radius \( R_{\text{AdS}} \) because in our formulation, it depends on the precise definition of UV cutoff. However, we can apply the argument of [12] and can heuristically argue that \( R_{\text{AdS}} \) is proportional to the central charge \( c \).

This solution is the minimum of \( S_L \) with the boundary condition \( e^{2\phi(z = \epsilon, x)} = \epsilon^{-2} \). For this, we rewrite (3) into

\[
S_L = \frac{c}{24\pi} \int dx dz [(\partial_x \phi)^2 + (\partial_z \phi)^2 + m e^{2\phi} + R_0 \phi],
\]

where \( R_0 \) is the Ricci scalar of the original space, which is zero in our setup here. The constant \( c \) is the central charge of two-dimensional CFT. The kinetic term in \( S_L \) describes the conformal anomaly and the potential term comes from UV regularization. In our treatment, \( \mu \) is an \( O(1) \) constant and we will simply set \( \mu = 1 \) by an appropriate shift of \( \phi \). For earlier relations between Liouville theory and three-dimensional gravity, refer to, e.g., [20], whose connections to our Letter are not obvious.

The ground-state wave functional \( \Psi_{g_{ab} = \epsilon^{2\phi} \delta_{ab}} \) computed from the path integral for the metric (3) is proportional to the one \( \Psi_{g_{ab} = \delta_{ab}} \) for the flat metric owing the conformal symmetry with the coefficient

\[
\Psi_{g_{ab} = \epsilon^{2\phi} \delta_{ab}}(\tilde{\varphi}(x)) = e^{S_L[\varphi] - S_L[0]} \cdot \Psi_{g_{ab} = \delta_{ab}}(\tilde{\varphi}(x)). \tag{7}
\]

Now we argue that the optimization is equivalent to minimizing the normalization \( e^{S_L[\varphi]} \) of the wave functional. The reason is that this factor measures the number of repetitions of the same operation (i.e. the path integral over a cell). In other words, the optimization chooses the most efficient Euclidean path integral.

Thus, the optimization can be completed by requiring the equation of motion of Liouville action \( S_L \)

\[
4 \partial_{ab} \partial_{ab} \phi = e^{2\phi}, \tag{8}
\]

where we introduced \( w = z + i x \) and \( \bar{w} = z - i x \). Its general solution is given by (see, e.g., [17, 21])

\[
e^{2\phi} = \frac{4 A'(w) B'(\bar{w})}{(1 - A(w) B(\bar{w}))^2}. \tag{9}
\]

Note that functions \( A(w) \) and \( B(\bar{w}) \) describe the degrees of freedom of conformal mappings.

First we choose the solution: \( A(w) = w, \quad B(\bar{w}) = -1/\bar{w} \). This leads to the Poincare metric \( H_2 \)

\[
e^{2\phi} = 4(w + \bar{w})^{-2} = z^{-2}. \tag{10}
\]

We argue that this is interpreted as the time slice of AdS3 dual to a holographic CFT. This is consistent with the tensor network description of AdS/CFT and can be regarded as its continuous version. Notice that we did not fix the overall normalization of the metric or equally the AdS radius \( R_{\text{AdS}} \) because in our formulation, it depends on the precise definition of UV cutoff. However, we can apply the argument of [12] and can heuristically argue that \( R_{\text{AdS}} \) is proportional to the central charge \( c \).

This solution is the minimum of \( S_L \) with the boundary condition \( e^{2\phi(z = \epsilon, x)} = \epsilon^{-2} \). For this, we rewrite (3) into

\[
S_L = \frac{c}{24\pi} \int dx dz [(\partial_x \phi)^2 + (\partial_z \phi)^2 + m e^{2\phi} + R_0 \phi],
\]

where \( R_0 \) is the Ricci scalar of the original space, which is zero in our setup here. The constant \( c \) is the central charge of two-dimensional CFT. The kinetic term in \( S_L \) describes the conformal anomaly and the potential term comes from UV regularization. In our treatment, \( \mu \) is an \( O(1) \) constant and we will simply set \( \mu = 1 \) by an appropriate shift of \( \phi \). For earlier relations between Liouville theory and three-dimensional gravity, refer to, e.g., [20], whose connections to our Letter are not obvious.
optimization of the quantum circuits, which defines the complexity.

Let us turn to the setup of a CFT on a cylinder, where the wave functional is defined on a circle \(|w| = 1\) at a fixed Euclidean time. After the optimization procedure, we obtain the geometry \(e^{2\phi(w, \bar{w})} = 4(1 - |w|^2)^{-\frac{1}{2}}\), which is precisely the Poincare disk and is the solution to \([5]\).

Now we consider an excited state given by a primary state. The excitation is described by a primary operator \(O(w, \bar{w})\) with the conformal dimension \(h = \bar{h}\). Its behavior under the Weyl rescaling is expressed as \(O(w, \bar{w}) \propto e^{-2h\phi}\). When we insert the operator \(O\) at the origin, the dependence of the wave function on \(\phi\) reads

\[
\Psi_{g_{ab}=\delta_{ab}} \equiv e^{S_L[\phi]-S[0]}e^{-2h\phi(0)}\Psi_{g_{ab}=\delta_{ab}}. \tag{12}
\]

Consider a CFT on a disk \(|w| < 1\) and insert a source at the center \(w = 0\). The equation of motion becomes

\[
4\partial_a\partial_\phi\phi - e^{2\phi} + 2\pi (1 - a)\delta^2(w) = 0, \tag{13}
\]

where we set

\[
a = 1 - 12\hbar/c. \tag{14}
\]

We can focus on the solutions \(A(w) = w^a\), \(B(\bar{w}) = \bar{w}^a\). The metric looks like

\[
e^{2\phi} = \frac{4a^2}{|w|^{2(1-a)}(1-|w|^{2a})^2}. \tag{15}
\]

Since the angle of \(w\) coordinate is \(2\pi\) periodic, this geometry has the deficit angle \(2\pi(1-a)\).

Let us compare this with the time slice of the gravity dual predicted from AdS3/CFT2. Indeed it is given by the deficit angle geometry \([15]\) with the identification

\[
a = \sqrt{1 - 24\hbar/c}. \tag{16}
\]

Thus, the geometry from our optimization \((14)\) agrees with the gravity dual \((10)\) when \(\hbar \ll c\), where the back reaction of the point particle is very small. This argument can also be generalized into an excitation at a generic point on the disk simply by acting the \(SL(2, R)\) symmetry of the AdS3 which preserves the time slice.

However, if we assume the quantum Liouville theory rather than the classical one, we find a perfect matching. In the quantum Liouville theory, we introduce a parameter \(\gamma\) such that \(c = 1 + 3Q^2\) with \(Q = \frac{1}{2} + \gamma\). The chiral conformal dimension of the operator \(e^{\frac{\beta}{2}\phi}\) is \(\frac{\beta(1-\beta)}{2}\). If \(c\) is large enough to have a classical gravity dual, we get

\[
a \simeq 1 - \beta\gamma \simeq \sqrt{1 - \frac{24\hbar}{c}}, \tag{16}
\]

which agrees with \((10)\).

This agreement suggests that the actual optimized wave functional is given by a “quantum” optimization

\[
\Psi_{\text{opt}}[\tilde{\phi}] = \left[ \int D\phi(z, x) e^{-S_L[\phi]} \right]^{-1} \Psi_{\phi_{++}=\delta_{ab}}. \tag{17}
\]

If we take the semiclassical approximation, we reproduce our classical optimization by minimizing \(S_L\).

We can extend our analysis to a finite temperature \(T = 1/\beta\) case. In the thermofield double description \([24]\), the wave functional is computed from a path integral on a cylinder with a finite width \(-\frac{\beta}{4}(\equiv z_1) < z < \frac{\beta}{4}(\equiv z_2)\) in the Euclidean time direction, more explicitly

\[
\Psi[\tilde{\phi}_1(x), \tilde{\phi}_2(x)] = \int \left( \prod_x \prod_{-\infty < z < \infty} D\phi(z, x) \right) e^{-S_{CF}T[\phi]} \times \prod_{-\infty < z < \infty} \delta(\phi(z_1, x) - \tilde{\phi}_1(x)) \delta(\phi(z_2, x) - \tilde{\phi}_2(x)), \tag{18}
\]

where \(\tilde{\phi}_1(x)\) and \(\tilde{\phi}_2(x)\) are the boundary values for the fields of the CFT (i.e. \(\tilde{\phi}(x)\)) at \(z = \pm \frac{\beta}{4}\), respectively.

By minimizing the Liouville action \(S_L\), we reach the solution \((14)\) given by: \(A(w) = e^{\frac{2\pi i}{\beta w}}\), \(B(\bar{w}) = -e^{\frac{2\pi i}{\beta \bar{w}}}\). This leads to

\[
e^{2\tilde{\phi}} = \frac{16\pi^2}{\beta^2} \frac{e^{\frac{2\pi i}{\beta}(w+\bar{w})}}{\left(1 + e^{\frac{2\pi i}{\beta}(w+\bar{w})}\right)^2} = \frac{4\pi^2}{\beta^2} \sec^2\left(\frac{2\pi z}{\beta}\right). \tag{19}
\]

This precisely agrees with the time slice of eternal Banados-Teitelboim-Zanelli (BTZ) black hole (i.e. the Einstein-Rosen bridge) \([24]\).

Consider an optimization of path integral representation of reduced density matrix \(\rho_A\). The subsystem \(A\) is chosen as an interval \(-l < x < l\). \(\rho_A\) is defined from the CFT vacuum by tracing out the complement of \(A\) (the upper left picture in Fig\([2]\)). The optimization is done by introducing the background metric as in \([4]\) where the Dirichlet boundary condition \(e^\phi = 1/\epsilon\) is imposed around the upper and lower edges of the slit \(A\). The optimization squeezes the infinitely extended plane into a finite-size region, corresponding to contracting tensors in tensor networks. Finally the geometry is obtained by pasting the two regions \(\Sigma_+\) along the boundaries \(\partial \Sigma_\pm\) (the upper right picture in Fig\([2]\)). The extremization of the bulk action \(S_L\) leads to the hyperbolic metric \([10]\).

The shape of the boundaries \(\partial \Sigma_\pm\) (we excluded the edges along \(A\)) is fixed by extremizing the boundary action in the Liouville theory \([25]\)

\[
S_{Lb} = \frac{c}{12\pi} \int_{\partial \Sigma_\pm} ds [K_0 \phi + \mu_B e^\phi], \tag{20}
\]

where \(K_0\) is the (trace of) extrinsic curvature of the boundary \(\partial \Sigma_\pm\) in the flat space. The final term is the boundary Liouville potential. Since \(\Sigma_+\) and \(\Sigma_-\) are pasted along the boundary smoothly, we set \(\mu_B = 0\) (actually \(\mu_B\) is related to the tension parameter in the gravity dual of a CFT on a manifold with boundaries \([26]\)).

By imposing the Neumann boundary condition of \(\phi\), we find the extrinsic curvature \(K\) in the curved metric \([4]\) is vanishing \(e^\phi K = (n^a\partial_a + n^\alpha \partial_\alpha)\phi + K_0 = 0\), where
we need a conformal symmetry breaking \[31\,34\], written by a Schwartzian derivative action as explicitly realized in the Sachdev-Ye-Kitaev (SYK) model. For the one-dimensional metric \(ds^2 = e^{2\phi} dt^2\), the Schwartzian derivative term reads \(N \int d\tau (\partial_\tau \phi)^2\), where \(N\) is a constant proportional to degrees of freedom. Thus, we find

\[
\Psi_{g_{rr} = e^{2\phi}(\hat{\phi}(x))} = e^{S_1(\hat{\phi}) - S_1(\phi)} \cdot \Psi_{g_{rr} = 1}(\hat{\phi}(x)),
\]

\[
S_1(\phi) = N \int d\tau \left( (\partial_\tau \phi)^2 + \mu e^\phi \right).
\]

(22)

The action minimization leads to \(ds^2 = e^{2\phi} dt^2 = \frac{dr^2}{r^2}\). This is consistent with the time slice of AdS2 spacetime. Note if there were no conformal symmetry breaking effect, we could not stabilize the optimization procedure.

Higher-dimensional generalizations of our optimization procedure are not straightforward as the generic metric cannot be expressed only by the Weyl scaling like \[41\]. Nevertheless, let us consider what optimization can lead to correct time slices of gravity duals by taking into account only the Weyl scaling degrees of freedom. We argue for the metric \[4\] with \(x\) regarded as \(d - 1\)-dimensional vector that the optimization can be done by minimizing the functional (again \(N\) describes degrees of freedom)

\[
S_d = N \int dx^{d-1} dz \left[ e^{\phi} + e^{(d-2)\phi} (\partial_x \phi)^2 + (\partial_z \phi)^2 \right].
\]

(23)

Indeed, the minimization of \(S_d\) leads to the hyperbolic space \(H_d\) which is the time slice of pure AdS\(_d+1\). Moreover, one parameter deformation of \(H_d\) is also a solution to the equation of motion for \(\phi\) and this deformed metric matches with that of the time slice of the AdS Schwarzschild black hole up to the first-order perturbation (details are described in the full paper \[10\]). For higher-order deformations, we expect quantum effects as in the AdS\(_3/CFT\_2\) case mentioned previously as in \[17\]. Also, for the \(H_d\) solution, we can estimate \(S_d \sim NV^d_{d-1}/e^{d-1}\), and this again agrees with the amount of complexity \[22\] and information metric \[23\].

In this Letter, we proposed an optimization procedure of the Euclidean path integral for quantum states in CFTs and gave an explicit formulation in terms of background metrics for two-dimensional CFTs. The optimization leads to the geometry which coincides with the time slice of its gravity dual. We argue that this provides a continuous version of the tensor network interpretation of AdS/CFT. When applied to a reduced density matrix, we naturally reproduce the entanglement wedge and the holographic entanglement entropy. At the same time, this gives a framework which calculates the computational complexity of quantum states in CFTs. Also this correspondence can be applied to the SYK model.

Moreover, we made a proposal on its higher-dimensional generalization and performed minimal checks. Another interesting future problem is to develop our formalism to calculate correlation functions in CFTs.
This will also be important to extend our method to nonconformal field theories. It is also important to extend our formalism to time-dependent backgrounds. These detailed studies are currently ongoing and we hope to report them in future publications.

of f by terminating the path-integral at various finite values by introducing the position dependent UV cut off. Using this deformed action, we obtain a flow of wave functions by terminating the path-integral at various finite values of z (see Fig.1), from the ground state to an unentangled state. This flow is very similar to the continuous MERA tensor network [12]. As in tensor networks, this deformation is far from unique. Our optimization procedure eliminates this ambiguity by minimizing action in the bulk. For simplicity, we take a two dimensional free real scalar field as an illustration. As in [12], the on-shell action with UV cutoff 1/ς is given by

\[ S[f] = \frac{1}{2} \int_{\epsilon}^{\infty} dz \int \frac{dk}{2\pi} \Gamma(ε|k|) · |k|^2 e^{-2|k|^z} f(k)f(-k), \]  

where \( \Gamma(x) \) is a cut off function such that \( \Gamma(x) = 0 \) \( (x > 1) \) and \( \Gamma(x) = 1 \) \( (x < 1) \); \( f(k) \) is the Fourier transform of \( f \) at \( z = \epsilon \). After \( x \) independent Weyl rescaling \( ds^2 = dz^2 + dx^2 \rightarrow e^{2φ(z)}(dz^2 + dx^2) \), the on-shell action becomes

\[ S[f, φ] = \frac{1}{2} \int_{\epsilon}^{\infty} dz \int \frac{dk}{2\pi} \Gamma(e^{-φ(z)}|k|) · |k|^2 e^{-2|k|^z} f(k)f(-k). \]

From the minimization of the Liouville action, we obtain \( e^{2φ} = \frac{1}{ς} · z^{-2} \). As a result, we find the deformed on-shell action with coordinate dependent cut off

\[ \Gamma(e^{-φ(z)}|k|) = \Gamma(z · \sqrt{ς} · |k|), \]

which agrees with the result based on the heuristic argument in [12].

**APPENDIX B: EXTRINSIC CURVATURES**

Consider a boundary \( x = f(z) \) in the two dimensional space defined by the metric \( ds^2 = e^{2φ(z,x)}(dz^2 + dx^2) \). The out-going normal unit vector \( N^a \) is given by

\[ N^z = e^{-φ(z,x)}n^z = \frac{-f'(z)e^{-φ(z,x)}}{\sqrt{1 + f'(z)^2}}, \]

\[ N^x = e^{-φ(z,x)}n^x = \frac{e^{-φ(z,x)}}{\sqrt{1 + f'(z)^2}}, \]

where \( n^a \) is the normal unit vector in the flat space \( ds^2 = dz^2 + dx^2 \). The extrinsic curvature \( = \text{its trace part} \) at the boundary is defined by \( K = h^{ab}N_aN_b \), where all components are projected to the boundary whose induced metric is written as \( h_ab \). Explicitly we can calculate \( K \) as follows:

\[ K = \frac{e^{-φ(z,x)}}{\sqrt{1 + f'(z)^2}} \left[ \partial_z φ - f'φ_z - \frac{f''}{1 + (f')^2} \right] \]

\[ = e^{-φ(z,x)}[n^aφ_{,a} + K_0], \]

where \( K_0 = -\frac{f''}{(1 + (f')^2)^{3/2}} \) is the extrinsic curvature of the boundary \( x = f(z) \) in the flat metric \( ds^2 = dz^2 + dx^2 \). Note that in the hyperbolic space \( φ = -\log z + \text{const.} \), the circle \( z^2 + x^2 = l^2 \) is a solution to \( K = 0 \) for any values of \( l \).

Note that by setting the variation of the action with respect to the infinitesimal shift of \( φ \) at the boundary for the total Liouville action \( S_T + S_Lb \) in the presence of \( μ_B \) of (20), we get the boundary condition

\[ K + μ_B = e^{-φ(z,x)}[n^aφ_{,a} + K_0] + μ_B = 0. \]  

Therefore the turning on \( μ_B \) means the boundary condition with the non-zero extrinsic curvature. Note that along the cut on the subsystem \( A \) at \( z = \epsilon \), we impose the Dirichlet boundary condition \( e^{φ} = 1/ς \). On the other boundary of \( \partialΣ⁺ \) (refer to Fig.2) i.e. on the half circle, we impose the Neumann boundary condition (29).

If we consider the boundary given by \( x^2 + (z-z_0)^2 = l^2 \), we get \( K = 0/ς \). When \( z_0 \) is infinitesimally small, we get \( x ≃ l + (z_0/ς) · z + O(z^2) \) near the boundary point \( (z, x) = (0, l) \). Therefore the corner angle is found to be \( π/2 - δ \) with \( δ ≃ -z_0/ς \) (for the definition of \( δ \), refer also to lower pictures in Fig.2). Therefore we find the relation \( K ≃ -δ \). For the \( n \)-sheeted replica geometry used in the main context of the letter, we chose \( μ_B = -K ≃ δ = π(1-n) \).

**APPENDIX C: ANOTHER DERIVATION OF ENTANGLEMENT ENTROPY**

Here we would like to present another computation of entanglement entropy. As in the standard replica method, this leads to the conical deficit angle \( 2π(1-n) \) at the two end points of the interval \( A \). Thus we have the contribution from the scalar curvature term in (18):

\[ \int_{Σ⁺} R_0 = 4π(1-n). \]

Since we know that the topology of the path-integrated space for \( ρ_A^\text{th} \) is the same as \( ρ_A \) i.e. the disk, we find \( \int_{∂Σ⁺} K_0 = 2π(1-n) \) so that the total Euler number does not depend on \( n \):

\[ \frac{1}{4π} \sum_{n=±} \left[ \int_{Σ_0} R_0 + 2 \int_{Σ_0} K_0 \right] = 0. \]

By evaluating the full Liouville action \( S_T + S_{Lb} \), the terms which are proportional to \( (n-1) \) are found as

\[ \frac{c}{24π} \sum_{n=±} \left[ \int_{Σ_0} R_0 + 2 \int_{∂Σ_0} K_0 φ \right] \] \[ \approx \frac{c}{3}(1-n) \text{log } \frac{l}{ς}. \]
Therefore the entanglement entropy is evaluated as reproducing the well-known result [30].

\[ S_A = -\left. \frac{\partial (S_L + S_{Lb})}{\partial n} \right|_{n=1} \simeq \frac{c}{3} \log \frac{l}{\epsilon}, \]  

(31)
