Abstract  Bourgain (A remark on the maximal function associated to an analytic vector field. Analysis at Urbana, Cambridge University Press, Cambridge, 1989) proved that the maximal operator associated with an analytic vector field is bounded on $L^2$. In the present paper, we give a geometric proof of Bourgain’s result by using the tools developed by Lacey and Li in (Trans Am Math Soc 358(9):4099–4117, 2006) and (Mem Am Math Soc 205 (965):viii+72, 2010).

Keywords  Maximal operators · Analytic vector fields · Time-frequency decomposition

Mathematics Subject Classification 42B20 · 42B25

1 Statement of the Main Result

Let $\Omega \subset \mathbb{R}^2$ be a bounded open set and $v : \Omega' \to S^1$ be a unit vector field defined on a neighborhood $\Omega'$ of the closure $\overline{\Omega}$ of $\Omega$. For a fixed small positive number $\epsilon_0 > 0$, define the maximal operator associated with the vector field $v$ truncated at the scale $\epsilon_0$ by

$$M_{v,\epsilon_0}f(x) := \sup_{\epsilon < \epsilon_0} \frac{1}{2\epsilon} \int_{-\epsilon}^{\epsilon} |f(x + tv(x))|dt. \quad (1.1)$$

In [3], Bourgain proved that
**Theorem 1.1** ([3]) Let \( v \) be real analytic on \( \Omega' \). Then for \( \epsilon_0 > 0 \) chosen small enough, \( M_{v, \epsilon_0} \) is bounded on \( L^2(\Omega) \).

**Remark 1.2** The \( L^p \) bounds (\( \forall p > 1 \)) for (1.1) and its singular integral variant

\[
H_{\epsilon_0} f(x) := \int_{-\epsilon_0}^{\epsilon_0} f(x + tv(x)) \frac{dt}{t} \tag{1.2}
\]

were obtained by Stein and Street [8] via a very different method. See also [4] for results concerning certain smooth vector fields.

To prove Theorem 1.1, Bourgain reduced the analyticity assumption on the vector field to the following geometric one: for \( x \in \Omega \) and \( t \) small enough, define the function

\[
\omega_x(t) = |\text{det}[v(x + tv(x)), v(x)]| \tag{1.3}
\]

We assume that

\[
|\{ t \in [-\epsilon, \epsilon] : \omega_x(t) < \tau \sup_{-\epsilon \leq s \leq \epsilon} \omega_x(s) \}| \leq C_0 \tau \epsilon_0 \epsilon, \tag{1.4}
\]

for all \( 0 < \tau < 1, 0 < \epsilon \leq \epsilon_0 \), where \( 0 < c_0, C_0 < \infty \) are constants independent of the point \( x \in \Omega \).

It is shown in [3] that Theorem 1.1 can be reduced to the following

**Theorem 1.3** ([3]) If \( v \) is \( C^1 \) and satisfies the condition (1.4), then \( M_{v, \epsilon_0} \) is bounded on \( L^2(\Omega) \).

Bourgain’s proof for Theorem 1.3 is not entirely geometric, especially in the key Lemma 3.28, where he used polar coordinates and applied Schur’s lemma to get the desired \( L^2 \) bounds.

The goal of this paper is to give a (relatively) geometric proof of Theorem 1.3. The idea is to use the time-frequency decomposition initiated by Lacey and Li in the setting of the Hilbert transform along vector fields in [6] and [7]. This decomposition was further developed by Bateman [1], Bateman and Thiele [2]. We refer to [5] for the detailed description of the progress that has been made for Hilbert transforms and maximal operators along vector fields.

This paper is free of time-frequency analysis techniques. Other than certain geometric lemmas (in the following Sect. 4), the tools that we will be using are only the elementary ones, for example Plancherel’s identity, the Cauchy–Schwarz inequality, Minkowski’s inequality and so on.

**Notation** Throughout this paper, we will write \( x \ll y \) to mean that \( x \leq y/10 \), \( x \lesssim y \) to mean that there exists a universal constant \( C \) s.t. \( x \leq Cy \), and \( x \sim y \) to mean that \( x \lesssim y \) and \( y \lesssim x \). \( \mathbb{1}_E \) will always denote the characteristic function of the set \( E \).
2 Reduction To a Smooth Cut-Off

By a renormalization, we assume further that $\|v\|_{C^1} \leq 1$, and $\Omega = B_{\epsilon_0}(0)$, which is the ball of radius $\epsilon_0 \ll 1$ centered at the origin. Moreover, as we are only concerned with the truncated maximal operator, we can w.l.o.g. assume that the vector field is periodic in both horizontal and vertical directions with each periodicity being $3 \cdot \epsilon_0$, and that the vector field always points in the two-ended cone which forms an angle less than $\pi/10$ with the horizontal axis. In the following, we will denote this cone by $\Gamma_1$.

Choose $\alpha : \mathbb{R} \to \mathbb{R}$ to be a proper smooth bump function such that the support of $\hat{\alpha}$ lies on $[-1, 1]$. For $0 < \epsilon \leq \epsilon_0$, define

$$A_{\epsilon} f(x) := \int_{\mathbb{R}} f(x + \epsilon t v(x)) \alpha(t) dt.$$  \hspace{1cm} (2.1)

It is not difficult to see that to bound the maximal function $M_{v, \epsilon_0} f$, it is essentially equivalent to bound

$$\sup_{j \in \mathbb{N}, 2^{-j} \leq \epsilon_0} |A_{2^{-j}} f(x)|,$$  \hspace{1cm} (2.2)

which will still be called $M_{v, \epsilon_0} f$. Moreover, we will write $A_j$ to stand for $A_{2^{-j}}$ for the sake of simplicity. Hence in the rest of the paper, we will focus on the following operator

$$M_{v, \epsilon_0} f(x) := \sup_{j \in \mathbb{N}, 2^{-j} \leq \epsilon_0} |A_j f(x)|,$$  \hspace{1cm} (2.3)

and prove that it is bounded on $L^2$.

3 Bourgain’s High-Low Frequency Decomposition

We linearize the maximal operator in (2.3): Take a measurable function $J : \mathbb{R}^2 \to \mathbb{N}$ such that

$$M_{v, \epsilon_0} f(x) \sim |A^{J(x)} f(x)|.$$  \hspace{1cm} (3.1)

For a point $x \in \Omega = B_{\epsilon_0}(0)$, let $R_{x,j}$ be the rectangle with center $x$, orientation $v(x)$, length $2^{-j}$ in direction $v(x)$ and width

$$\delta(R_{x,j}) = 2^{-j} \cdot \sup_{|t| < 2^{-j}} \omega_x(t).$$  \hspace{1cm} (3.2)

We especially denote

$$\delta(x) := 2^{-J(x)} \cdot \sup_{|t| < 2^{-J(x)}} \omega_x(t).$$  \hspace{1cm} (3.3)

Choose a measurable function $K : \mathbb{R}^2 \to \mathbb{N}$ such that

$$\delta(x) \sim 2^{-K(x)}, \forall x \in \mathbb{R}^2.$$  \hspace{1cm} (3.4)
Let $\psi : \mathbb{R} \to \mathbb{R}$ be a non-negative smooth function supported on $[1/2, 5/2]$, with $\psi(t) = 1$ for all $t \in [1, 2]$. For $k \in \mathbb{Z}$, define a Littlewood–Paley operator $P_k$ by

$$P_k f(x) = \int_{\mathbb{R}^2} \hat{f}(\xi) \psi(2^{-k} |\xi|) e^{ix \cdot \xi} d\xi. \quad (3.5)$$

Do a Littlewood–Paley decomposition for the function $f$, and write $f = \sum_{k \in \mathbb{Z}} P_k f$. This turns our linearized maximal operator into

$$\sum_{k \in \mathbb{Z}} A^{J(x)} P_k f(x). \quad (3.6)$$

Bourgain’s idea is to split the function $f$ into two parts, the high frequency part and the low frequency part, in the following way:

$$\sum_{k \in \mathbb{Z}} A^{J(x)} P_k f(x) = \sum_{k \in \mathbb{Z}, k \geq K(x)} A^{J(x)} P_k f(x) + \sum_{k \in \mathbb{Z}, k < K(x)} A^{J(x)} P_k f(x). \quad (3.7)$$

For the latter part, i.e., the low frequency part, Bourgain’s proof is already geometric; see Lemma 4.12 and Lemma 5.7 in [3]. Hence the main task for us is to bound the former part, i.e., the high frequency part, by a geometric argument.

**Remark 3.1** The estimate of the above high frequency part is done in Lemma 3.28 in [3] via analytic methods.

We proceed with the estimate of the high frequency part: First we write

$$\sum_{k \in \mathbb{Z}, k \geq K(x)} A^{J(x)} P_k f(x) = \sum_{l \in \mathbb{N}_0} A^{J(x)} P_{K(x) + l} f(x). \quad (3.8)$$

Then by the triangle inequality, it suffices to prove that

$$\| A^{J(x)} P_{K(x) + l} f(x) \|_2 \lesssim 2^{-\mu l} \| f \|_2,$$

for some $\mu > 0$, with a constant being independent of $l \in \mathbb{N}$.

Notice that the above estimate is still of a maximal type, and we want to get rid of the linearization by replacing the $l^\infty$ norm by an $l^2$ norm. To do this, we need to introduce some notation. For $j, k \in \mathbb{N}$, define

$$\Omega_{j,k} := \left\{ x \in \Omega \mid 2^{-j} \sup_{|t| < 2^{-j}} \omega_x(t) \sim 2^{-k} \right\}. \quad (3.10)$$

For a real analytic vector field, either the integral curves are straight lines, or for each $j \in \mathbb{N}$, the complement of the set $\cup_k \Omega_{j,k}$ has measure zero. Hence it is no restriction to assume for each $j \in \mathbb{N}$ that

$$\Omega = \bigcup_{k \in \mathbb{N}} \Omega_{j,k}. \quad (3.11)$$
It is also clear that for a fixed \( k \in \mathbb{N} \), the \( \Omega_{j,k} \) for different \( j \) are disjoint. Hence for a fixed \( x \),

\[
|A^j(x) P_K(x) + f(x)| \lesssim \sup_{j \in \mathbb{N}} \left( \sum_{k \in \mathbb{N}} |A^j P_{k+l} f|^2 \mathbb{1}_{\Omega_{j,k}} \right)^{1/2}.
\]  

(3.12)

We replace the sup norm by the \( l^2 \) norm to obtain

\[
|A^j(x) P_K(x) + f(x)| \lesssim \left( \sum_{j \in \mathbb{N}} \sum_{k \in \mathbb{N}} |A^j P_{k+l} f|^2 \mathbb{1}_{\Omega_{j,k}} \right)^{1/2}.
\]  

(3.13)

Taking the \( L^2 \) norm of (3.13), we obtain

\[
\sum_{j \in \mathbb{N}} \sum_{k \in \mathbb{N}} \int |A^j P_{k+l} f|^2 \mathbb{1}_{\Omega_{j,k}}.
\]  

(3.14)

Recall that \( R_{x,j} \) denotes the rectangle with center \( x \), length \( 2^{-j} \) and width

\[
\delta(R_{x,j}) := 2^{-j} \sup_{|t| < 2^{-j}} \omega_x(t).
\]  

(3.15)

In the following we will cover \( \Omega_{j,k} \) by rectangles \( \{ R_m = R_{x_m,j} \}_{m \in \mathbb{N}} \) satisfying the following two conditions

\[
(i) \delta(R_m) = 2^{-k}; \quad (ii) \text{the center of } R_m \text{ does not belong to } R_1 \cup \cdots \cup R_{m-1}.
\]  

(3.16)

Hence for fixed \( j \) and \( k \),

\[
\int |A^j P_{k+l} f|^2 \mathbb{1}_{\Omega_{j,k}} \lesssim \sum_{m \in \mathbb{N}} \int |A^j P_{k+l} f|^2 \mathbb{1}_{R_m}.
\]  

(3.17)

Indeed, the above covering of \( \Omega_{j,k} \) is a “valid” covering, i.e., a covering without much overlapping. To be precise, if we define

\[
\Omega'_{j,k} := \bigcup_{x \in \Omega_{j,k}} 2 \cdot R_{x,j},
\]  

(3.18)

then it has been proved by Bourgain in [3] (see the following Lemma 4.5) that

\[
\| \sum_j \mathbb{1}_{\Omega'_{j,k}} \|_{\infty} \lesssim 1.
\]  

(3.19)

\( \odot \) Springer
In the following, when estimating the right-hand side of (3.17), we will need several other geometric properties like (3.19). Hence we organize all of them together in the next section.

4 Geometric Properties of Rectangles

In this section we collect several geometric lemmas that will play crucial roles in the forthcoming calculation. Most of these lemmas have already been proven by Bourgain [3]. Here we still include them, as well as their proofs, for the sake of completeness. Moreover, for certain technical reasons, we will still need several variants of these geometric lemmas, which are the following Lemmas 4.3 and 4.6.

**Lemma 4.1** (Lemma 4.1 in [3]) Let \( x' \) be in the rectangle \( R_{x,j} \). Then

\[
\delta(R_{x,j}) \sim \delta(R_{x',j}),
\]

and \( R_{x,j} \) is contained in a multiple of \( R_{x',j} \) and vice versa.

**Proof of Lemma 4.1** Recall the definition

\[
\delta(R_{x,j}) = 2^{-j} \cdot \sup\limits_{|t| < 2^{-j}} \omega_x(t),
\]

and

\[
\omega_x(t) = |\det[v(x + tv(x)), v(x)]| \sim |v(x + tv(x)) - v(x)|.
\]

Here we will prove

\[
\sup\limits_{|t| < 2^{-j}} \omega_x(t) \lesssim \sup\limits_{|t| < 2^{-j}} \omega_{x'}(t).
\]

The other direction of the inequality in (4.4) can be proven in the same way. First, we write

\[
x' = x + \alpha v(x) + y,
\]

with

\[
|\alpha| \lesssim 2^{-j} \quad \text{and} \quad |y| \lesssim 2^{-j} \sup\limits_{|t| < 2^{-j}} \omega_x(t).
\]

Now for a given \( |t_0| < 2^{-j} \), we estimate

\[
|v(x + t_0v(x)) - v(x)| \lesssim |v(x') - v(x' - \alpha v(x) - y)| + |v(x') - v(x' + (t_0 - \alpha)v(x) - y)|.
\]

Both terms on the right-hand side of the last display have the same structure (just \( \alpha \) from the first term is replaced by \( t_0 - \alpha \)), hence we will only consider the first term. By the triangle inequality, it can be bounded by

\[
|v(x') - v(x' - \alpha v(x'))| + |v(x' - \alpha v(x) - y) - v(x' - \alpha v(x'))|.
\]
The first term in (4.8) is bounded by $\sup_{|t|<2^{-j}} \omega_{x'}(t)$. The second term is bounded by

$$|\alpha(v(x') - v(x)) - y| \lesssim |\alpha||v(x + \alpha v(x)) - v(x)| + |y|. \quad (4.9)$$

Collecting all these estimates, we arrive at

$$\sup_{|t|<2^{-j}} \omega_{x}(t) \lesssim \sup_{|t|<2^{-j}} \omega_{x'}(t) + 2^{-j} \sup_{|t|<2^{-j}} \omega_{x}(t). \quad (4.10)$$

Recall that $2^{-j} \leq \epsilon_0$, hence (4.10) implies (4.4) if we choose $\epsilon_0$ small enough.

**Lemma 4.2** (Lemma 4.6 in [3]) Assume

$$2 \cdot R_{x,j} \cap 2 \cdot R_{x',j'} \neq \emptyset, \quad (4.11)$$

and $2^{-j'} \lesssim 2^{-j}$. Then there exists a universal constant $C > 0$ such that

$$R_{x',j'} \subset C \cdot R_{x,j} \quad (4.12)$$

and

$$\frac{\delta(R_{x,j})}{2^{-j}} \gtrsim \frac{\delta(R_{x',j'})}{2^{-j'}}. \quad (4.13)$$

Namely, the larger rectangle has the larger eccentricity.

**Proof of Lemma 4.2** We will only prove (4.12). It immediately implies (4.13). Take $x_0 \in 2 \cdot R_{x,j} \cap 2 \cdot R_{x',j'}$. By Lemma 4.1, we have

$$R_{x',j'} \subset R_{x',j} \subset C \cdot R_{x,j} \subset C^2 R_{x,j}. \quad (4.14)$$

This finishes the proof of (4.12).

**Lemma 4.3** Assume that

$$R_{x,j} \cap R_{x',j'+j_0} \neq \emptyset, \quad (4.15)$$

for some $j_0 \in \mathbb{N}_0$. Then there exists a constant $a_0 > 1$ such that

$$\frac{\delta(R_{x,j})}{2^{-j}} \lesssim (2^{j_0})^{a_0} \cdot \frac{\delta(R_{x',j'+j_0})}{2^{-j-j_0}}. \quad (4.16)$$

**Remark 4.4** Compared with Lemma 4.2, this lemma says that the growth of the eccentricity of a rectangle with respect to its length can only be polynomial.

**Proof of Lemma 4.3** This follows easily from Lemma 4.1 and the following doubling estimate (3.20) in [3]

$$\frac{\delta(R_{x,j})}{2^{-j}} \leq C \cdot \frac{\delta(R_{x',j+1})}{2^{-j-1}}, \quad (4.17)$$

for some constant $C > 0$. Moreover, (4.17) is an immediate consequence of (1.4).
Lemma 4.5 (Lemma 4.7 in [3]) Let \( \{R_{x_i,j_i}\}_{i\in\mathbb{N}_0} \) be a sequence of rectangles and \( \delta > 0 \) such that

\[
(i) \quad \delta(R_{x_i,j_i}) \sim \delta; \\
(ii) \quad x_{i+1} \text{ does not belong to } R_{x_0,j_0} \cup \cdots \cup R_{x_i,j_i}, \forall i.
\]

Then

\[
\| \sum_{i\in\mathbb{N}_0} 1_{2R_{x_i,j_i}} \|_\infty \lesssim 1.
\]

Proof of Lemma 4.5 Suppose \( 2 \cdot R_{x_0,j_0} \cap 2 \cdot R_{x_1,j_1} \neq \emptyset \) and \( j_0 \geq j_1 \). By (4.13),

\[
\frac{\delta}{2^{-j_1}} \gtrsim \frac{\delta}{2^{-j_0}},
\]

which further implies \( 2^{j_0} \lesssim 2^{j_1} \). That means, for two such intersecting rectangles with the same width, they also have comparable lengths. From this observation, the estimate (4.19) follows immediately. \( \square \)

We will also need the following generalized version of the above lemma.

Lemma 4.6 Under the same assumptions as in Lemma 4.5, there exists a constant \( b_0 > 0 \) such that for any \( N \in \mathbb{N}_0 \), we have

\[
\| \sum_{i\in\mathbb{N}_0} 1_{R_{p,q}^{x_i,j_i}} \|_\infty \lesssim (p + q + 1)^{b_0}, \forall p, q \in \mathbb{N},
\]

where \( R_{p,q}^{x_i,j_i} \) is obtained by dilating the length of \( R_{x_i,j_i} \) to \( p \) times, and the width to \( q \) times.

Remark 4.7 The above lemma says that when we enlarge the rectangles \( R_{x_i,j_i} \), their overlapping can only be polynomially growing.

Proof of Lemma 4.6 Denote

\[
\tilde{q} := \max\{q, p^{a_0+1}\},
\]

where \( a_0 \) is the constant in (4.16). For the rectangle \( R_{p,q}^{x_i,j_i} \), we further enlarge it to be of width \( \tilde{q} \cdot \delta \). Next, we will dilate the length to \( \tilde{p}_i \cdot 2^{-j_i} \) such that

\[
\sup_{|t| \leq \tilde{p}_i \cdot 2^{-j_i}} \omega_{x_i}(t) \sim \frac{\tilde{q}}{\tilde{p}_i} \cdot \frac{\delta}{2^{-j_i}}.
\]

By Lemma 4.2, it is not difficult to see that

\[
\tilde{p}_i \leq \tilde{q} \lesssim \tilde{p}_i^{a_0+1},
\]

\( \square \) Springer
uniformly in $i$.

Our goal now is to show that
\[
\| \sum_i \mathbb{1}_{R_{x_i,j_i}} \|_{\infty} \lesssim \tilde{q}^{b_0},
\]  
(4.25)

for some $b_0$ to be determined later. Suppose that the $L^\infty$ norm on the left-hand side of the above expression is attained at the point $O$. Moreover, let $\mathcal{R}_O$ denote the collection of rectangles containing the point $O$. W.l.o.g. we assume that
\[
\mathcal{R}_O = \{ R_{x_i,j_i}^0 \}_{0 \leq i \leq N},
\]  
(4.26)

for some $N \in \mathbb{N}_0$. Then (4.25) is equivalent to proving
\[
N \lesssim \tilde{q}^{b_0}.
\]  
(4.27)

By the definition of the rectangles $R_{x_i,j_i}^0$ and Lemma 4.1, it is not difficult to see that all the rectangles in $\mathcal{R}_O$ have comparable lengths. Indeed, up to a constant dilation factor, any of these rectangles is contained in another. Hence
\[
\bigcup_{0 \leq i \leq N} R_{x_i,j_i}^0 \subset 4R_{x_0,j_0}^0,
\]  
(4.28)

Moreover, by the upper bound on $\tilde{p}_i$ in (4.24), we can also obtain that
\[
l(R_{x_i,j_i}) \gtrsim l(R_{x_0,j_0}^0) / \tilde{q},
\]  
(4.29)

where for a rectangle $R$, $l(R)$ is used to denote its length. Hence by the assumption that the center $x_i$ of $R_{x_i,j_i}$ is not contained in
\[
R_{x_0,j_0} \cup \cdots \cup R_{x_{i-1},j_{i-1}}
\]  
(4.30)

for all $i$, we obtain easily the estimate (4.27) for some constant $b_0$ depending only on $a_0$. So far we have finished the proof of Lemma 4.6. \hfill \Box

5 Estimate on Each Rectangle

We proceed with the estimate of the right-hand side of (3.17). In this section, we will prove an estimate for fixed $j, k, l$ and for a given rectangle $R_m$. Here $R_m$ is a rectangle of length $2^{-j}$ and width $2^{-k}$.

Recall that we have assumed that the vector field points in the cone $\Gamma_0$, which is the two-ended cone forming an angle less than $\pi/10$ with the horizontal axis. If we denote by $P_{\Gamma_0}$ the frequency projection operator on the cone $\Gamma_0$, it is not difficult to see that
\[
A^j P_{k+i} P_{\Gamma_0} f \equiv 0.
\]  
(5.1)
Hence in the following we will only be concerned with the frequency in the cone $\Gamma_0^c$. Moreover, for the sake of simplicity, we will always identify $P_{k+l}$ with $P_{k+l}P_{\Gamma_0^c}$.

5.1 Time-Frequency Decomposition of the Function $P_{k+l}f$

Most of the content in this subsection is taken from Bateman [1]. Here we will make some modifications as we will be dealing with all frequency annuli instead of one single annulus.

**Frequency decomposition** For the fixed $j, k$ and $l$, we will denote

$$\theta := k + l - j.$$  \hspace{1cm} (5.2)

Let $D_\theta$ be the collection of the dyadic intervals of length $2^{-\theta}$ contained in $[-20, 20]$. Fix a smooth positive function $\beta : \mathbb{R} \to \mathbb{R}$ s.t.

$$\beta(x) = 1, \forall |x| \leq 1; \beta(x) = 0, \forall |x| \geq 2.$$  \hspace{1cm} (5.3)

Also choose $\beta$ such that $\sqrt{\beta}$ is a smooth function. For each $\omega \in D_\theta$, define

$$\beta_\omega(x) = \beta(2^\theta (x - c_\omega)),$$  \hspace{1cm} (5.4)

where $c_\omega$ denotes the center of the interval $\omega$. Define

$$\beta_\theta(x) = \sum_{\omega \in D_\theta} \beta_\omega(x).$$  \hspace{1cm} (5.5)

Notice that

$$\beta_\theta(x + 2^{-\theta}) = \beta_\theta(x), \forall x \in [-20, 20 - 2^{-\theta}].$$  \hspace{1cm} (5.6)

Define

$$\gamma_\theta = \frac{1}{20} \int_{-10}^{10} \beta_\theta(x + t) dt.$$  \hspace{1cm} (5.7)

Because of the above periodicity, we know that $\gamma_\theta$ is constant for $x \in [-10, 10]$, independently of $\theta$. Say $\gamma_\theta(x) = \gamma > 0$, hence

$$\frac{1}{\gamma} \cdot \gamma_\theta(x) 1_{[-10,10]}(x) = 1_{[-10,10]}(x).$$  \hspace{1cm} (5.8)

Define another multiplier $\tilde{\beta} : \mathbb{R} \to \mathbb{R}$ with support in $[\frac{1}{2}, \frac{5}{2}]$ and $\tilde{\beta}(x) = 1$ for $x \in [1, 2]$. We define the corresponding multipliers on $\mathbb{R}^2$:

$$\hat{m}_{k+l,\omega}(\xi, \eta) = \tilde{\beta}(2^{k-l+1}\eta)\beta_\omega\left(\frac{\xi}{\eta}\right)$$

$$\hat{m}_{k+l,\theta,t}(\xi, \eta) = \tilde{\beta}(2^{k-l+1}\eta)\beta_\theta\left(t + \frac{\xi}{\eta}\right)$$
\[ \hat{m}_{k+l,\theta}(\xi, \eta) = \hat{\beta}(2^{-k-l}\eta)\gamma_{\theta}\left(\frac{\xi}{\eta}\right). \]

Using the above multipliers, we obtain
\[ A^j P_{k+l}f = A^j (m_{k+l,\theta} \ast f) = \frac{1}{20} \int_{-10}^{10} A^j (m_{k+l,\theta,t} \ast f) dt. \quad (5.9) \]

Hence it suffices to prove a uniform bound on \( t \in [-10, 10] \). W.l.o.g. we will just consider the case \( t = 0 \), which is
\[ A^j (m_{k+l,\theta,0} \ast f) = \sum_{\omega \in \mathcal{D}_\theta} A^j (m_{k+l,\omega} \ast f). \quad (5.10) \]

**Space (Time) decomposition** For \( \omega \in \mathcal{D}_\theta \), let \( \mathcal{U}_{k+l,\omega} \) be a partition of \( \mathbb{R}^2 \) by rectangles of width \( 2^{-k-l} \) and length \( 2^{-j} \), whose long sides have slope \( -c_\omega \) with \( c_\omega \) denoting the center of the interval \( \omega \). If \( s \in \mathcal{U}_{k+l,\omega} \), we will write \( \omega_s := \omega \).

**Definition 5.1** For a rectangle \( R \subset \mathbb{R}^2 \) of slope less than one, with \( l(R) \) its length, \( w(R) \) its width, we define its uncertainty interval \( \text{EX}(R) \) to be the interval of width \( w(R)/l(R) \) and centered at \( \text{slope}(R) \).

**Remark 5.2** For a tile \( s \in \mathcal{U}_{k+l,\omega} \), we have that \( \text{EX}(s) = -\omega \).

An element of \( \mathcal{U}_{k+l,\omega} \) for some \( \omega \in \mathcal{D}_\theta \) is called a “tile”. Define \( \varphi_{k+l,\omega} \) such that
\[ |\hat{\varphi}_{k+l,\omega}|^2 = \hat{m}_{k+l,\omega}; \quad (5.11) \]
then \( \varphi_{k+l,\omega} \) is smooth by our assumption on \( \beta \) mentioned above.

For a tile \( s \in \mathcal{U}_{k+l,\omega} \), define
\[ \varphi_s(p) := \sqrt{|s|}\varphi_{k+l,\omega}(p - c_s), \quad (5.12) \]
where \( c_s \) is the center of \( s \). Notice that
\[ \|\varphi_s\|^2_2 = \int_{\mathbb{R}^2} |s|\varphi_{k+l,\omega}^2 = |s| \int_{\mathbb{R}^2} \hat{m}_{k+l,\omega} = 1, \quad (5.13) \]
i.e., \( \varphi_s \) is \( L^2 \) normalized.

The construction of the tiles above by the uncertainty principle is to localize functions further in space; for this purpose we need

**Lemma 5.3** ([11]) Under the above notation, for the frequency localized function \( f \ast m_{k+l,\omega} \), we have
\[ f \ast m_{k+l,\omega}(x) = \lim_{N \to \infty} \frac{1}{4N^2} \int_{[-N,N]^2} \sum_{s \in \mathcal{U}_{k+l,\omega}} \langle f, \varphi_s(p + \cdot) \rangle \varphi_s(p + x) dp. \quad (5.14) \]
The above lemma allows us to pass the expression in (5.10) to the model sum
\[
\sum_{\omega \in D_0} \sum_{s \in U_{k+l, o}} \langle f, \varphi_s \rangle A^j \varphi_s.
\]

**Definition 5.4** For a unit vector \( v = (v_1, v_2) \in \mathbb{R}^2 \), for an interval \( I \subset \mathbb{R} \), we say that \( v \in I \) if the slope of the line that is perpendicular to \( v \) lies in \( I \).

**Lemma 5.5** ([1, 6]) we have that \( A^j \varphi_s(x) = 0 \) unless \( v(x) \in \omega_s \).

To have this lemma is the main reason for replacing the strict cut-off by a smooth cut-off in Sect. 2. The proof of Lemma 5.5 is simply by the Plancherel theorem. From this lemma we know that in order for the output \( A^j \varphi_s \) not to vanish at a point \( x \), the vector field at \( x \) has to point roughly to the direction of the long side of the tile \( s \).

### 5.2 Estimate on Each Rectangle By Ignoring the Tails of the Wavelet Functions

After the above preparation, we turn to the estimate of each term on the right-hand side of (3.17), which is
\[
\int \left| A^j P_{k+l} f \right|^2 \mathbb{1}_{R_m} = \int \left| \sum_{\omega \in D_0} \sum_{s \in U_{k+l, o}} \langle f, \varphi_s \rangle A^j \varphi_s \right|^2 \mathbb{1}_{R_m}.
\]  
(5.15)

By Lemma 5.5, we have that the right-hand side of (5.15) is equal to
\[
\sum_{\omega \in D_0} \int \left| \sum_{s \in U_{k+l, o}} \langle f, \varphi_s \rangle A^j \varphi_s \right|^2 \mathbb{1}_{R_m}.
\]  
(5.16)

In this subsection, we will only show the ideas of how to bound the above term, or in other words, we will ignore the tails of the wavelet functions and the function \( \alpha \) in the definition of \( A^j \) in (2.1), and always assume that they have compact support in both space and frequency.

Under the above simplification, the expression in (5.16) becomes
\[
\sum_{\omega \in D_0} \sum_{s \in U_{k+l, o}} |\langle f, \varphi_s \rangle|^2 2 \int \left| A^j \varphi_s \right|^2 \mathbb{1}_{R_m}.
\]  
(5.17)

Take a point \( x \in R_m \); for a tile \( s \in U_{k+l, o} \) for some \( \omega \in D_0 \), we observe that in order for \( A^j \varphi_s(x) \) not to vanish, we must have \( \omega \subset 3 \cdot EX(R_m) \) as by Lemma 4.1 we know that \( v(x) \in 2 \cdot EX(R_m) \) for any \( x \in R_m \). This, together with the fact that both \( R_m \) and \( s \) have length \( 2^{-j} \), implies that
\[
s \subset 4 \cdot R_m,
\]  
(5.18)

for those tiles \( s \) such that \( A^j \varphi_s \) is not identically zero.
Claim 5.6 There exists $\mu > 0$ such that
\[
\int |A^j \varphi_s|^2 \mathbb{1}_{R_m} \lesssim 2^{-\mu l},
\] (5.19)
with the constant being independent of $s$.

By the above claim, the expression in (5.17) can be further bounded by
\[
\sum_{\omega \in D_0} \sum_{s \in U_{k+l,\omega, s \subset 4\cdot R_m}} 2^{-\mu l} \cdot |\langle f, \varphi_s \rangle|^2 \lesssim 2^{-\mu l} \|1_{R_m} \cdot P_{k+l} f\|_2^2.
\] (5.20)

The next step is to sum over $m$, $j$ and $k$:
\[
\sum_{j, k} \sum_{m} \|1_{R_m} \cdot P_{k+l} f\|_2^2 \lesssim 2^{-\mu l} \sum_{j, k} \|\Omega'_{j,k} \cdot P_{k+l} f\|_2^2 \lesssim 2^{-\mu l} \|f\|_2^2,
\] (5.21)
where we have used the disjointness property (3.19). Hence for the model problem, what remains is

Proof of Claim 5.6 We can w.l.o.g. assume that there exists a point $x_0 \in s$ such that $v(x_0) \in \omega_s$, as otherwise $A^j \varphi_s$ will be identically zero. By a proper translation and rotation, we can assume that $x_0 = (0, 0)$ and $v(x_0) = (1, 0)$.

Now we look at the directions of the vector field at the points lying on the line segment
\[
\{(x_1, x_2) : x_2 = 0\} \cap s.
\] (5.22)
By the assumption on the rectangle $R_m$ we know that
\[
\sup_{|t| \leq 2^{-j}} w_{x_0}(t) = \sup_{|t| \leq 2^{-j}} |\det[v(x_0 + tv(x_0)), v(x_0)]| \sim 2^{-k+j}.
\] (5.23)
Notice that $|\omega_s| = 2^{-k-l+j}$, hence in order for $A^j \varphi_s$ not to vanish at a point $x \in s \cap \{(x_1, x_2) : x_2 = 0\}$, we must have
\[
|\det[v(x), v(x_0)]| = w_{x_0}(x \cdot v(x_0)) \lesssim 2^{-k-l+j}.
\] (5.24)
By taking $\tau = 2^{-l}$ in the condition (1.4) we obtain
\[
\left| t \in [-2^{-j}, 2^{-j}] : w_{x_0}(t) < 2^{-l} \sup_{|t| \leq 2^{-j}} w_{x_0}(t) \right| \leq C_0 2^{-c_0 l} \cdot 2^{-j},
\] (5.25)
which further implies that
\[
\left| \{(x_1, 0) \in s : A^j \varphi_s(x_1, 0) \neq 0\} \right| \lesssim 2^{-c_0 l} \cdot 2^{-j}.
\] (5.26)
So far we have proved that on one line segment, the non-vanishing output $A^j \varphi_s(x) \neq 0$ has relatively small measure. In the next, we want to show that this indeed holds true for all the points in the tile $s$, namely

$$\{|x \in s : A^j \varphi_s(x) \neq 0\| \lesssim 2^{-c_0 l} |s|.$$  \hfill (5.27)

This, combined with the trivial estimate

$$\|A^j \varphi_s\|_{\infty} \lesssim |s|^{-1/2},$$  \hfill (5.28)

concludes the proof of Claim 5.6. \hfill \Box

We turn to the proof of (5.27): For $|x_2| \leq 2^{-k-l+2}$, consider the line segment

$$L_{x_2} := \{(0, x_2) + t \cdot v(0, x_2) : |t| \leq 2^{-j+2}\}. \hfill (5.29)$$

First, by the $C^1$ assumption on the vector field, we know that

$$v(0, x_2) \in 2 \cdot \omega_s, \forall |x_2| \leq 2^{-k-l+2}.$$  \hfill (5.30)

Then, by the same argument as before, we obtain that

$$|\{x \in L_{x_2} : A^j \varphi_s(x) \neq 0\| \lesssim 2^{-c_0 l} \cdot 2^{-j},$$  \hfill (5.31)

for each $|x_2| \leq 2^{-k-l+2}$. Hence by Fubini’s theorem (which can be applied due to the $C^1$ assumption on the vector field), we obtain

$$|\{x \in L_{x_2} : A^j \varphi_s(x) \neq 0\| dx_2 \lesssim 2^{-c_0 l} \cdot 2^{-k-l-j}.$$  \hfill (5.32)

Hence we have finished the proof of (5.27).

### 5.3 The Full Estimate on Each Rectangle

In this subsection, we will make the above heuristic argument rigorous, i.e., we will also take care of the tails of the wavelet functions. For fixed $j, k, l$ and $m$, we want to bound the following

$$\int |A^j P_{k+l} f \mathbb{1}_{R_m}|^2 = \sum_{s \in \mathcal{U}_{k+l,\omega}} \left| \sum_{x \in s} \langle f, \varphi_x \rangle A^j \varphi_s \right|^2 \mathbb{1}_{R_m}.$$  \hfill (5.33)

For $p, q \in \mathbb{Z}$, we denote by $\tilde{R}^{p,q}_m$ the translation of the rectangle $R_m$ by $(p, q)$ units, i.e.,

$$\tilde{R}^{p,q}_m = R_m + p \cdot 2^{-j} v(x_m) + q \cdot 2^{-k} v^\perp(x_m).$$  \hfill (5.34)
where $x_m$ denotes the center of $R_m$ and $v(x_m)$ is the value of the vector field at the point $x_m$ which is parallel to the long side of $R_m$.

Hence for one fixed $\omega \in \theta$, we have

$$
\int \left| \sum_{s \in \mathcal{U}_{k+l,oo}} \langle f, \varphi_s \rangle A^j \varphi_s \right|^2 \mathbb{I}_{R_m} = \int \left| \sum_{p,q \in \mathbb{Z}} \sum_{s \in \mathcal{U}_{k+l,oo}, s \subset \tilde{R}_{m}^{p,q}} \langle f, \varphi_s \rangle A^j \varphi_s \right|^2 \mathbb{I}_{R_m}.
$$

(5.35)

By Minkowski’s inequality, the right-hand side of the above display can be bounded by

$$
\left( \sum_{p,q \in \mathbb{Z}} \left( \int \left| \sum_{s \in \mathcal{U}_{k+l,oo}, s \subset \tilde{R}_{m}^{p,q}} \langle f, \varphi_s \rangle A^j \varphi_s \mathbb{I}_{R_m} \right|^2 \right)^{1/2} \right)^2.
$$

(5.36)

**Lemma 5.7** For any large $M \in \mathbb{N}_0$, there exists a constant $C_M$ such that

$$
\int \left| \sum_{s \in \mathcal{U}_{k+l,oo}, s \subset \tilde{R}_{m}^{p,q}} \langle f, \varphi_s \rangle A^j \varphi_s \right|^2 \mathbb{I}_{R_m} \lesssim \frac{C_M \cdot 2^{-\mu l}}{(|p| + |q| + 1)^M} \sum_{s \in \mathcal{U}_{k+l,oo}, s \subset \tilde{R}_{m}^{p,q}} |\langle f, \varphi_s \rangle|^2,
$$

(5.37)

where $\mu$ is the same as the one in Claim 5.6.

We substitute the estimate in Lemma 5.7 into (5.36) to obtain

$$
\left( \sum_{p,q \in \mathbb{Z}} \left( \frac{2^{-\mu l}}{(|p| + |q| + 1)^M} \sum_{s \in \mathcal{U}_{k+l,oo}, s \subset \tilde{R}_{m}^{p,q}} |\langle f, \varphi_s \rangle|^2 \right)^{1/2} \right)^2 \lesssim \sum_{p,q \in \mathbb{Z}} \frac{2^{-\mu l}}{(|p| + |q| + 1)^M} \sum_{s \in \mathcal{U}_{k+l,oo}, s \subset \tilde{R}_{m}^{p,q}} |\langle f, \varphi_s \rangle|^2,
$$

(5.38)

where the exact value of $M$ might vary from line to line. Hence we have obtained

$$
\int \left| A^j P_{k+l} f \right|^2 \mathbb{I}_{R_m} \lesssim \sum_{\omega \in \mathcal{D}_0} \sum_{p,q \in \mathbb{Z}} \frac{2^{-\mu l}}{(|p| + |q| + 1)^M} \sum_{s \in \mathcal{U}_{k+l,oo}, s \subset \tilde{R}_{m}^{p,q}} |\langle f, \varphi_s \rangle|^2,
$$

(5.39)

which is the estimate on one single rectangle that we are aiming at.

**Proof of Lemma 5.7** We will only consider the case $p = q = 0$. The decay in $p$ and $q$ in the other case will simply follow from the non-stationary phase method. Hence
what we need to prove becomes
\[
\int \left| \sum_{s \in U_{k+l, \omega}, s \subset R_m} \langle f, \varphi_s \rangle A^j \varphi_s \right|^2 \mathbb{I}_{R_m} \lesssim 2^{-\mu l} \sum_{s \in U_{k+l, \omega}, s \subset R_m} |\langle f, \varphi_s \rangle|^2.
\] (5.40)

Recall that each tile \(s\) has width \(2^{-k-l}\); however, the rectangle \(R_m\) has width \(2^{-k}\). This suggests that we should do a further partition of \(R_m\) into smaller rectangles which will be of the same dimension as \(s\).

We enumerate the tiles \(s \subset R_m\) from above to below by \(s_1, s_2, \ldots, s_{m'}, \ldots\), where \(m' \lesssim 2^l\). Notice that
\[
R_m \subset \bigcup_{m'} 2 \cdot s_{m'}.
\] (5.41)

Hence
\[
\int \left| \sum_{s \in U_{k+l, \omega}, s \subset R_m} \langle f, \varphi_s \rangle A^j \varphi_s \right|^2 \mathbb{I}_{R_m} \lesssim \sum_{m'} \int \sum_{m''} \left| \langle f, \varphi_{s_{m''}} \rangle A^j \varphi_{s_{m''}} \right|^2 \mathbb{I}_{2 \cdot s_{m''}}.
\] (5.42)

By the Cauchy–Schwarz inequality, we bound the right-hand side of the above expression by
\[
\sum_{m'} \int \sum_{m''} \left| \langle f, \varphi_{s_{m''}} \rangle A^j \varphi_{s_{m''}} \right|^2 (|m' - m''| + 1)^M \mathbb{I}_{2 \cdot s_{m''}},
\] (5.43)

for some large constant \(M\). By the same argument as in the proof of Claim 5.6, we obtain
\[
|\{x \in 2 \cdot s_{m'} : A^j \varphi_{s_{m'}} \neq 0\}| \lesssim 2^{-c_0l} |s_{m'}|.
\] (5.44)

This, together with the trivial bound
\[
\|A^j \varphi_{s_{m''}}\|_{L^\infty(s_{m''})} \lesssim \frac{|s_{m''}|^{1/2}}{(|m' - m''| + 1)^{2M}},
\] (5.45)

implies that
\[
\int \left| \langle f, \varphi_{s_{m''}} \rangle A^j \varphi_{s_{m''}} \right|^2 \mathbb{I}_{2 \cdot s_{m''}} \lesssim \frac{2^{-c_0l}}{(|m' - m''| + 1)^{2M}} |\langle f, \varphi_{s_{m''}} \rangle|^2.
\] (5.46)

We substitute the above estimate into (5.43) to obtain
\[
\sum_{m'} \sum_{m''} \frac{2^{-c_0l}}{(|m' - m''| + 1)^M} |\langle f, \varphi_{s_{m''}} \rangle|^2 \lesssim \sum_{m''} |\langle f, \varphi_{s_{m''}} \rangle|^2.
\] (5.47)

So far we have finished the proof of Lemma 5.7, hence the estimate on each rectangle, which is (5.39).
6 Organizing All Rectangles to Finish the Proof

In this section, we will organize the estimates on all the rectangles together, i.e., to finish the proof of the following estimate

$$\sum_j \sum_k \sum_m \int \left| A^j P_{k+l} f \right|^2 1_{R_m} \lesssim 2^{-\mu l} \| f \|_2^2,$$  \hspace{1cm} (6.1)

for some $\mu > 0$. To do this, we substitute the estimate (5.39) into the left-hand side of the above expression to obtain

$$\sum_j \sum_k \sum_m \sum_{\omega \in D_\theta} \sum_{p,q \in \mathbb{Z}} 2^{-\mu l} (|p| + |q| + 1)^M \sum_{s \in \mathcal{U}_{k+l,\omega,s} \subset R_m^{p,q}} |\langle f, \varphi_s \rangle|^2,$$  \hspace{1cm} (6.2)

where we are still using the notation $\theta = k + l - j$. Hence it suffices to prove that for fixed $p, q \in \mathbb{Z}$, we have

$$\sum_j \sum_k \sum_m \sum_{\omega \in D_\theta} \sum_{s \in \mathcal{U}_{k+l,\omega,s} \subset R_m^{p,q}} |\langle f, \varphi_s \rangle|^2 \lesssim (|p| + |q| + 1)^{b_0} \| f \|_2^2,$$  \hspace{1cm} (6.3)

where $b_0$ is the constant in Lemma 4.6.

**Proof of the estimate (6.3)** We first fix $k$. For the case $p = q = 0$, for two tiles $s'$ and $s''$ in the following collection

$$\bigcup_j \bigcup_{\omega \in D_\theta} \bigcup_m \{s : s \in \mathcal{U}_{k+l,\omega,s} \subset R_m\},$$  \hspace{1cm} (6.4)

we either have

$$\omega_{s'} \cap \omega_{s''} = \emptyset,$$  \hspace{1cm} (6.5)

or

$$s' \cap s'' = \emptyset.$$  \hspace{1cm} (6.6)

Hence by the (almost) orthogonality, we obtain that

$$\sum_j \sum_k \sum_m \sum_{\omega \in D_\theta} \sum_{s \in \mathcal{U}_{k+l,\omega,s} \subset R_m} |\langle f, \varphi_s \rangle|^2 \lesssim \| P_{k+l} f \|_2^2.$$  \hspace{1cm} (6.7)

By summing over $k$, we get the desired estimate (6.3) for the case $p = q = 0$.

For the general $p, q \in \mathbb{Z}$, we no longer have (6.6) due to the simple fact that for two disjoint rectangles (of different dimensions), they might intersect after being translated by $(p, q)$ units separately. Fortunately, Lemma 4.6 says that the intersection caused by translation can only grow polynomially in $p$ and $q$. 

Springer
Hence by essentially the same idea as above and by losing a factor of $(|p| + |q| + 1)^{b_0}$, we obtain

$$\sum_j \sum_m \sum_{\omega \in D_0} \sum_{s \in \mathcal{U}_{k+1, \omega}, s \subset \vec{R}^p_q} |\langle f, \varphi_s \rangle|^2 \lesssim (|p| + |q| + 1)^{b_0} \| P_{k+1} f \|_2^2. \quad (6.8)$$

Summing over $k$, we get the estimate (6.3). So far we have finished the proof of (6.1), hence the geometric proof of Theorem 1.1.

Acknowledgements The author would like to thank his advisor, Prof. Christoph Thiele, for sharing with him this problem and for many valuable discussions. The author also thanks Po-Lam Yung for reading the manuscript and giving many helpful suggestions.
