Higgs and Z-boson FCNC decays correlated with B-meson decays
in littlest Higgs model with T-parity

Institute of Theoretical Physics, Academia Sinica, Beijing 100080, China

Abstract

In the littlest Higgs model with T-parity (LHT) new flavor-changing interactions between mirror fermions and the Standard Model (SM) fermions can induce various FCNC decays for B-mesons, Z-boson and Higgs boson. Since all these decays induced in the LHT model are correlated, we in this work perform a collective study for these decays, namely the Z-boson decay $Z \rightarrow b\bar{s}$, the Higgs boson decay $h \rightarrow b\bar{s}$, and the B-meson decays $B \rightarrow X_s\gamma$, $B_s \rightarrow \mu^+\mu^-$ and $B \rightarrow X_s\mu^+\mu^-$. We find that under the current experimental constraints from the B-decays, the branching ratios of both $Z \rightarrow b\bar{s}$ and $h \rightarrow b\bar{s}$ can still deviate from the SM predictions significantly. In the parameter space allowed by the B-decays, the branching ratio of $Z \rightarrow b\bar{s}$ can be enhanced to $10^{-7}$ (about one order above the SM prediction) while $h \rightarrow b\bar{s}$ can be much suppressed relative to the SM prediction (about one order below the SM prediction).

I. INTRODUCTION

The fancy idea of little Higgs [1] tries to provide an elegant solution to the hierarchy problem by regarding the Higgs boson as a pseudo-Goldstone boson whose mass is protected by an approximate global symmetry and free from one-loop quadratic sensitivity to the cutoff scale. The littlest Higgs model [2] is a cute economical implementation of the little Higgs idea, but is found to be subject to strong constraints from electroweak precision tests [3], which would require raising the mass scale of the new particles to far above TeV scale and thus reintroduce the fine-tuning in the Higgs potential [4]. To tackle this problem, a discrete symmetry called T-parity is proposed [5], which forbids the tree-level contributions from the heavy gauge bosons to the observables involving only SM particles as external states. However, in such littlest Higgs model with T-parity (LHT) [5], there arise new flavor-changing interactions between mirror fermions and the SM fermions (just like the flavor-changing interactions between sfermions and fermions in supersymmetric models). Such new flavor-changing interactions can have crucial phenomenology, especially they can induce various flavor-changing neutral-current (FCNC) processes, which should be examined.

Among various FCNC processes induced by the new flavor-violating interactions in the LHT model, the loop-induced B-decays, such as $B \to X_s \gamma$, $B_s \to \mu^+ \mu^-$ and $B \to X_s \mu^+ \mu^-$, should be first checked due to the available experimental data on these decays. Recently, these B-decays have been intensively examined in the LHT model, which were found to be sensitive to the new flavor-violating interactions [6, 7, 8]. Note that in addition to these B-decays, the loop-induced FCNC decays of Higgs and Z-boson, such as $Z \to b \bar{s}$ and $h \to b \bar{s}$ which are strongly correlated with the FCNC B-decays, should also be examined since they are sensitive to the flavor structure of new physics. In the future there may be at least two avenues in which Z-bosons will be produced in much larger quantities than at LEP. At the CERN Large Hadron Collider (LHC) with an integrated luminosity of 100 fb$^{-1}$, one expects $5.5 \times 10^9$ Z-bosons to be produced [9]. In particular, the GigaZ option at the proposed International Linear Collider (ILC) with an integrated luminosity of 30 fb$^{-1}$, it is possible to produce more than $10^9$ Z-bosons [10]. For the study of the Higgs boson, one may expect the ILC to scrutinize the Higgs boson property after the discovery at the LHC.

These rare decays $Z \to b \bar{s}$ and $h \to b \bar{s}$ have been studied in the SM [11] and in various new physics models [12, 13]. In this work we will study these decays in the LHT model.
Since such decays are strongly correlated with the induced FCNC B-decays ($B \to X_s \gamma$, $B_s \to \mu^+ \mu^-$ and $B \to X_s \mu^+ \mu^-$), we will collectively consider all these decays. We will first check the analytic results of these B-decays given in [6, 7, 8] and then perform their numerical calculations together with $Z \to b \bar{s}$ and $h \to b \bar{s}$. We will show the constraints on the parameter space from current B-decay experiments and display the results for $Z \to b \bar{s}$ and Higgs boson decay $h \to b \bar{s}$ with/without the B-decay constraints.

This work is organized as follows. In Sec. II we recapitulate the LHT model and address the new flavor violating interactions which will contribute to the FCNC decays considered in this work. In Sec. III, IV and V we examine the B-decays ($B \to X_s \gamma$, $B_s \to \mu^+ \mu^-$ and $B \to X_s \mu^+ \mu^-$), Z-boson decay $Z \to b \bar{s}$ and Higgs boson decay $h \to b \bar{s}$, respectively. Finally, we give our conclusion in Sec. VI.

II. THE LITTLEST HIGGS MODEL WITH T-PARITY

The LHT model [5] is based on a non-linear sigma model describing the spontaneous breaking of a global $SU(5)$ down to a global $SO(5)$ by a $5 \times 5$ symmetric tensor at the scale $f \sim \mathcal{O}(\text{TeV})$. From the $SU(5)/SO(5)$ breaking, there arise 14 Goldstone bosons which are described by the ”pion” matrix $\Pi$, given explicitly by

$$
\Pi = \begin{pmatrix}
-\frac{\omega_0}{\sqrt{2}} - \frac{\eta}{\sqrt{20}} & -\frac{\omega^+}{\sqrt{2}} & -i\frac{\pi^+}{\sqrt{2}} & -i\phi^{++} & -i\phi^+ \\
-\frac{\omega^-}{\sqrt{2}} & \frac{\omega_0}{\sqrt{2}} - \frac{\eta}{\sqrt{20}} & \frac{v+h+i\pi^0}{2} & -i\phi^+ & -i\phi^0 + \phi^0 \\
i\frac{\pi^-}{\sqrt{2}} & \frac{v+h-i\pi^0}{2} & \sqrt{4/5}\eta & -i\frac{\pi^+}{\sqrt{2}} & \frac{v+h+i\pi^0}{2} \\
i\phi^- & i\phi^- & \frac{\phi^-}{\sqrt{2}} & -\frac{\omega^0}{\sqrt{2}} - \frac{\eta}{\sqrt{20}} & -\frac{\omega^-}{\sqrt{2}} \\
i\phi^+ & i\phi^+ & \frac{\phi^+}{\sqrt{2}} & \frac{\omega^0}{\sqrt{2}} + \frac{\eta}{\sqrt{20}} & \frac{\omega^0}{\sqrt{2}} - \frac{\eta}{\sqrt{20}} 
\end{pmatrix}.
$$

Under T-parity the SM Higgs doublet $H = (-i\pi^+ / \sqrt{2}, (v + h + i\pi^0)/2)^T$ is T-even, while the other fields are T-odd. A subgroup $[SU(2) \times U(1)]_1 \times [SU(2) \times U(1)]_2$ of the $SU(5)$ is gauged, and at the scale $f$ it is broken into the SM electroweak symmetry $SU(2)_L \times U(1)_Y$. The Goldstone bosons $\omega^0$, $\omega^\pm$ and $\eta$ are respectively eaten by the new T-odd gauge bosons $Z_H$, $W_H$ and $A_H$, which obtain masses at $\mathcal{O}(v^2/f^2)$

$$
M_{W_H} = M_{Z_H} = fg \left(1 - \frac{v^2}{8f^2}\right), \quad M_{A_H} = \frac{fg'}{\sqrt{5}} \left(1 - \frac{5v^2}{8f^2}\right),
$$

(2)
with \( g \) and \( g' \) being the SM \( SU(2) \) and \( U(1) \) gauge couplings, respectively.

The Goldstone bosons \( \pi^0 \) and \( \pi^\pm \) are eaten by the SM T-even \( Z \)-boson and \( W \)-boson, which obtain masses at \( \mathcal{O}(v^2/f^2) \),

\[
M_{W_L} = \frac{gv}{2} \left( 1 - \frac{v^2}{12f^2} \right), \quad M_{Z_L} = \frac{gv}{2 \cos \theta_W} \left( 1 - \frac{v^2}{12f^2} \right). \tag{3}
\]

The photon \( A_L \) is also T-even and massless. Due to the mass of SM bosons corrected at \( \mathcal{O}(v^2/f^2) \), the relation between \( G_F \) and \( v \) is modified from its SM form and is given by

\[
\frac{1}{v^2} = \sqrt{2} G_F (1 - \frac{v^2}{6f^2}).
\]

The top quark has a T-even partner \( T \) quark and a T-odd \( T^- \) quark. To leading order, their masses are given by

\[
M_T = \frac{m_t f}{v} (r + \frac{1}{r}), \quad M_{T^-} = M_T \frac{1}{\sqrt{1 + r^2}}, \tag{4}
\]

where \( r = \lambda_1/\lambda_2 \) with \( \lambda_1 \) and \( \lambda_2 \) being the coupling constants in the Lagrangian of the top quark sector [5]. Furthermore, for each SM quark (lepton), a copy of mirror quark (lepton) with T-odd quantum number is added in order to preserve the T-parity. We denote them by

\[
u^i_H, d^i_H, \nu^i_H, l^i_H, \]

where \( i = 1, 2, 3 \) are the generation index. In \( \mathcal{O}(v^2/f^2) \) their masses satisfy

\[
m_{\nu^i_H} = \sqrt{2} \kappa_{\nu^i} f, \quad m_{d^i_H} = m_{\nu^i_H} (1 - \frac{v^2}{8f^2}). \tag{5}\]

Here \( \kappa_{\nu^i} \) are the diagonalized Yukawa couplings of the mirror quarks.

Note that new flavor interactions arise between the mirror fermions and the SM fermions, mediated by the T-odd gauge bosons or T-odd Goldstone bosons. In general, besides the charged-current flavor-changing interactions, the FCNC interactions between the mirror fermions and the SM fermions can also arise from the mismatch of rotation matrices. For example, there exist FCNC interactions between the mirror down-type quarks and the SM down-type quarks, where the mismatched mixing matrix is denoted by \( V_{H_d} \). We follow [6, 8] to parameterize \( V_{H_d} \) with three angles \( \theta_{12}^d, \theta_{23}^d, \theta_{13}^d \) and three phases \( \delta_{12}^d, \delta_{23}^d, \delta_{13}^d \):

\[
\begin{pmatrix}
  c_{12}^d c_{13}^d & s_{12}^d c_{13}^d e^{-i\delta_{12}^d} & s_{13}^d e^{-i\delta_{13}^d} \\
-s_{12}^d c_{23}^d e^{i\delta_{12}^d} - c_{12}^d s_{23}^d e^{i\delta_{13}^d} & c_{12}^d c_{23}^d - s_{12}^d s_{23}^d e^{i\delta_{13}^d} & s_{23}^d e^{i\delta_{23}^d} \\
 s_{12}^d s_{23}^d e^{i(\delta_{12}^d + \delta_{23}^d)} - c_{12}^d s_{13}^d e^{i\delta_{13}^d} & -c_{12}^d s_{23}^d e^{i\delta_{13}^d} - s_{12}^d c_{23}^d e^{i\delta_{23}^d} & c_{23}^d c_{13}^d
\end{pmatrix}. \tag{6}
\]
III. FCNC B-DECAYS

The decays $B \to X_s \gamma$, $B_s \to \mu^+ \mu^-$ and $B \to X_s \mu^+ \mu^-$ can be induced at loop level by the new flavor-changing interactions in the LHT model and have been recently studied in [8]. We check the results of [8] and make the following brief descriptions about these decays without giving the detailed expressions (all functions in our following discussions can be found in [8]).

(1) For $B \to X_s \gamma$ the LHT contributions enter through the modifications of the quantities

$$T_{SM}^{D'} \equiv \lambda_t^{(s)} D'_0(x_t) = -2\lambda_t^{(s)} C_{7\gamma}^0(M_W), \quad T_{SM}^{E'} \equiv \lambda_t^{(s)} E'_0(x_t) = -2\lambda_t^{(s)} C_{8G}^0(M_W),$$

where the CKM factor $\lambda_t^{(s)} = V_{ts} V_{tb}^*$ and $C_{7\gamma}^0$ and $C_{8G}^0$ are leading-order Wilson coefficients. With the LHT effects $T_{SM}^{D'}$ and $T_{SM}^{E'}$ are replaced by $T^{D'}$ and $T^{E'}$

$$T^{D'} = T_{D'}^{even} + T_{D'}^{odd}, \quad T^{E'} = T_{E'}^{even} + T_{E'}^{odd},$$

where the superscripts 'even' and 'odd' denote the contributions from T-even and T-odd particles, respectively. Note that for the LHT contributions we only consider the leading-order effects while for the SM prediction we consider the next-to-leading-order QCD corrections. Actually, the SM prediction for $B \to X_s \gamma$ has been calculated to the NNLO [14].

(2) The branching ratio of $B_s \to \mu^+ \mu^-$ in the SM depends on a function $Y_{SM}$ and the LHT effects enter through the modification of $Y_{SM}$ [8]. With the LHT effects $Y_{SM}$ is replaced by

$$Y_s = Y_{SM} + \bar{Y}_{even}^{odd} \lambda_t^{(s)},$$

where $\bar{Y}_{even}$ and $\bar{Y}_{odd}$ represent the effects from T-even and T-odd particles, respectively. The branching ratio normalized to the SM prediction is then given by

$$\frac{Br(B_s \to \mu^+ \mu^-)}{Br(B_s \to \mu^+ \mu^-)_{SM}} = \left| \frac{Y_s}{Y_{SM}} \right|^2$$

with $Br(B_s \to \mu^+ \mu^-)_{SM} = 3.66 \times 10^{-9}$.

(3) The branching ratio of $B \to X_s \mu^+ \mu^-$ in the SM depends on the functions $Y_{SM}$, $Z_{SM}$ and $D'_0(x_t)$ ($Y_{SM}$ and $D'_0$ are same as in $B_s \to \mu^+ \mu^-$ and $B \to X_s \gamma$) and the LHT
effects enter through the modification of these functions. The modifications of $Y_{SM}$ and $D'_0$ have been given above, and the modification of $Z_{SM}$ is given by 

$$Z_s = Z_{SM} + \tilde{Z}_{even} + \frac{\tilde{Z}_{odd}}{\lambda^{(s)}},$$

(11)

where $\tilde{Z}_{even}$ and $\tilde{Z}_{odd}$ represent the effects from T-even and T-odd particles, respectively.

(4) For the experimental values of these three B-decays, they are given by

$$Br(B \rightarrow X_s \gamma) = (3.52 \pm 0.23 \pm 0.09) \times 10^{-4} \ (E_\gamma > 1.6\text{GeV}),$$

$$Br(B_s \rightarrow \mu^+ \mu^-) < 7.5 \times 10^{-8},$$

$$Br(B \rightarrow X_s \mu^+ \mu^-) = 4.3^{+1.3}_{-1.2} \times 10^{-6}.$$  

(12)

Note that throughout this work we perform our calculations in the ‘t Hooft-Feynman gauge and the SM input parameters involved are taken from [16].

IV. Z-BOSON FCNC DECAY $Z \rightarrow b\bar{s}$

The relevant Feynman diagrams are shown in Fig. 1. The LHT contributions are from both T-even and T-odd particles. The contributions of T-even particles include both the SM contributions and the contributions of the top quark T-even partner (T-quark). The diagrams of T-odd particles are induced by the interactions between the SM quarks and the mirror quarks mediated by the heavy T-odd gauge bosons or Goldstone bosons. The calculations of the loop diagrams in Fig. 1 are straightforward. Each loop diagram is composed of some scalar loop functions [17], which are calculated by using LOOPTOOLS [18]. The relevant Feynman rules can be found in [8]. We have checked that the divergences of T-even contributions are canceled at $O(\nu^2/f^2)$. For the contributions of T-odd particles, the divergences are not canceled at $O(\nu^2/f^2)$, which are from the diagrams with T-odd Goldstone bosons. Such left-over divergence in the LHT model was first found in the calculation of $B_s \rightarrow \mu^+ \mu^-$ and $B \rightarrow X_s \mu^+ \mu^-$ in [8], and was understood as the sensitivity of the decay amplitudes to the ultraviolet completion of the theory. In our numerical calculations we follow [8] to remove the divergent term $1/\varepsilon$ and take the renormalization scale $\mu = \Lambda$ with $\Lambda = 4\pi f$ being the cutoff scale of the LHT model.
our numerical calculations we relax the constraints on the parameters $\delta_c$ precision data [19], which, however, depend on the masses of T-odd fermions and the parameter $\delta_c$ (its value is related to the details of the ultraviolet completion of the theory). Hence, in our numerical calculations we relax the constraints on the parameters $f$ and $r$, and let them vary in the range

$$500 \text{ GeV} \leq f \leq 1500 \text{ GeV}, \quad 0.5 \leq r \leq 2.0.$$  

(13)

In addition to the parameters $f$ and $r$, the matrix $V_{Hd}$ and the masses of $d^i_H$ ($i = 1, 2, 3$) are also involved in our calculations. To simplify our calculations, we follow [8] to consider three scenarios for these parameters:

(I) We assume $V_{Hd} = 1$ or assume the degeneracy for the masses of $d^i_H$, i.e., $m_{d^1_H} = m_{d^2_H} = m_{d^3_H}$. In the former case, we have no flavor mixing between mirror down-type quarks and the SM down-type quarks and thus the loop contributions of T-odd particles vanish. In the latter case, due to the relation of Eq. (8), the masses of $u^i_H$ are also degenerate. Then, due to the unitarity of the flavor mixing matrices between mirror quarks and the SM quarks, the loop contributions of T-odd particles vanish. The remained contributions from the loops of T-even particles depend on two parameters,
i.e., the breaking scale $f$ and the ratio $r$.

(II) We assume $V_{Hd} = V_{CKM}$. In this scenario, in addition to the contributions of T-even particles, the T-odd particles will also come into play. The parameters involved are then $f$, $r$, $m_{d_H}$ and $m_{\nu_H}$ (the loop contributions to $B_s \rightarrow \mu^+\mu^-$ and $B \rightarrow X_s\mu^+\mu^-$ involve the mirror lepton masses $m_{\nu_H}$). As shown in Eq.(15), the masses of mirror fermions are proportional to $f$, which are assumed as

$$
\begin{align*}
    m_{\nu_H^1} &= \frac{500 \text{ GeV}}{\text{TeV}} f, \\
    m_{d_H^1} &= \frac{600 \text{ GeV}}{\text{TeV}} f, \\
    m_{d_H^2} &= \frac{1400 \text{ GeV}}{\text{TeV}} f.
\end{align*}
$$

We checked that the parameters taken here satisfy the constraints from the four-fermion interaction operators [20].

(III) We keep $\delta_{13}^d$ as a free parameter, while for other parameters in the matrix $V_{Hd}$ we assume

$$
\delta_{12}^d = \delta_{23}^d = 0, \quad \frac{1}{\sqrt{2}} \leq s_{12}^d \leq 0.99, \quad 5 \times 10^{-5} \leq s_{23}^d \leq 2 \times 10^{-4}, \quad 4 \times 10^{-2} \leq s_{13}^d \leq 0.6. \tag{15}
$$

For the masses $m_{d_H}$ and $m_{\nu_H}$, we take the same assumption as in scenario II.

![Graph](image_url)

**FIG. 2:** Scatter plots for the branching ratio of $Z \rightarrow s\bar{b} + b\bar{s}$ versus $f$. The bullets (blue) and the crosses (red) are allowed and excluded by the 2$\sigma$ B-decay constraints, respectively.

We scan over the parameters in the ranges specified above. For the three scenarios we obtain the scatter plots in Fig. 2, where we also show the constraints from the B-decays $B \rightarrow X_s\gamma$, $B_s \rightarrow \mu^+\mu^-$ and $B \rightarrow X_s\mu^+\mu^-$.  

8
Fig. 2 shows that the contributions are sensitive to the scale $f$ and for lower values of $f$ the derivation from the SM prediction is more sizable. The constraints from B-decays are significant, with scenario-III being most stringently restrained. In the parameter space allowed by the $2\sigma$ experimental bounds of these B-decays, the branching ratio of $Z \to s\bar{b} + b\bar{s}$ can reach the order of $10^{-7}$, which is about one order above the SM prediction.

V. HIGGS BOSON FCNC DECAY $h \to b\bar{s}$

The relevant Feynman diagrams involving T-even particles in the loops can be obtained from the corresponding diagrams in Fig. 1 by replacing $Z$-boson with the Higgs boson. For the contributions of T-odd particles, the diagrams are more complicate. Note that the divergence of T-odd contributions for $h \to b\bar{s}$ is at $\mathcal{O}(1)$ and is more severe than in B-decays or Z-decay where the divergence appears at $\mathcal{O}(v^2/f^2)$. Such divergence is mainly due to the absence of Fig. 1(i) with the down-type mirror quarks in the loops since the Higgs boson does not couple with the down-type mirror quarks. Since such left-over divergences in the T-odd contributions appear at $\mathcal{O}(1)$, the prediction is subject to severe theoretical uncertainty although we can treat the divergences in the same way as for Z-decay and B-decays discussed above. Unlike the uncertainty in Z-decay which is correlated with the uncertainty in B-decays (and thus can be restrained by B-decays), the uncertainty in $h \to b\bar{s}$ caused by such T-odd contributions cannot be constrained by B-decays since the contributions of the diagrams mediated by the Higgs boson can be neglected in the B-decays. To avoid such large unconstrained uncertainty caused by T-odd contributions, we perform numerical calculations only for scenario-I where the T-odd contributions vanish.

To evaluate the branching ratio of $h \to b\bar{s}$ we need to know the total decay width of the Higgs boson. In addition to the decay channels in the SM, there arise a new important channel $h \to A_H A_H$ ($A_H$ is a candidate for the cosmic dark matter), which may be dominant in some parameter space of the LHT model [21]. The total decay width is given by

$$\Gamma_{\text{total}} \approx \Gamma_{h \to \text{fermions}} + \Gamma_{h \to W_L W_L} + \Gamma_{h \to Z_L Z_L} + \Gamma_{h \to A_H A_H}. \quad (16)$$

In Fig. 3 (a) we scan over $r$ and $f$ in the ranges in Eq. (13) and present the scatter plots for the branching ratio with $m_h = 140$ GeV. In Fig. 3 (b) we show the dependence of the branching ratio on the Higgs boson mass by fixing the parameters $r$ and $f$ allowed by the
electroweak precision data and B-decays. In our calculations we kept the order up to $\mathcal{O}(v/f)$ and checked that the divergences are canceled to this order.

From Fig. 3 we see that the branching ratio in the LHT model is below the SM prediction and the deviation is significant for low values of $f$. In the parameter space allowed by the B-decays at $2\sigma$ level, the branching ratio can be one order below the SM prediction due to the fact that in some parameter space the decay $h \to A_H A_H$ may be dominant and greatly enhance the total width.

VI. CONCLUSION

The littlest Higgs model with T-parity may have flavor problem since it predicts new flavor-changing interactions between mirror fermions and the Standard Model fermions, which can induce various FCNC decays. Since all these decays induced in this model are correlated, we in this work performed a collective study for the FCNC decays of B-mesons, Z-boson and Higgs boson. We found that under the current experimental constraints from the B-decays, the branching ratios of both $Z \to b\bar{s}$ and $h \to b\bar{s}$ can still deviate from the SM predictions significantly. In the parameter space allowed by the B-decays, the branching
ratio of $Z \rightarrow b\bar{s}$ can be enhanced to $10^{-7}$ (about one order above the SM prediction) while $h \rightarrow b\bar{s}$ can be much suppressed relative to the SM prediction (about one order below the SM prediction).

We remark that unlike the FCNC B-decays, it is quite challenging to test these rare Z-boson and Higgs boson decays at collider experiments. For instance, to test this rare decay of Z-boson, we may need the GigaZ option of the ILC. Theoretically, for the test of the LHT model, these rare decays are complementary to the direct production of T-quark [22] and the production of top quark or Higgs boson [23] whose cross sections can be sizably altered by the LHT model.
