(Dated: November 14, 2014)

Abstract

We study the light-quark mass and spatial volume dependence of the matrix elements of $\Delta B = 0$ four-quark operators relevant for the determination of $V_{ub}$ and the lifetime ratios of single-$b$ hadrons. To this end, one-loop diagrams are computed in the framework of heavy hadron chiral perturbation theory with partially quenched formalism for three light-quark flavors in the isospin limit; flavor-connected and -disconnected diagrams are carefully analyzed. These calculations include the leading light-quark flavor and heavy-quark spin symmetry breaking effects in the heavy hadron spectrum. Our results can be used in the chiral extrapolation of lattice calculations of the matrix elements to the physical light-quark masses and to infinite volume. To provide insight on such chiral extrapolation, we evaluate the one-loop contributions to the matrix elements containing external $B_d$, $B_s$ mesons and $\Lambda_b$ baryon in the QCD limit, where sea and valence quark masses become equal. In particular, we find that the matrix elements of the $\lambda_3$ flavor-octet operators with external $B_d$ meson receive the contributions solely from connected diagrams in which current lattice techniques are capable of precise determination of the matrix elements. Finite volume effects are at most a few percent for typical lattice sizes and pion masses.

Keywords:
I. INTRODUCTION

In inclusive decays of single-$b$ hadrons, spectator effects play an important role in extracting their decay widths and the lifetimes of different species, because the light constituent quarks in a parent hadron participate in the weak process. For a number of years there have been suggestions that the $\Lambda_b$ lifetime in particular had significant corrections from spectator effects [1, 2]. Recent measurements tend to favor more natural values [3]:

$$\frac{\tau(B^+)}{\tau(B_d)} = 1.079 \pm 0.007, \quad \frac{\tau(B_s)}{\tau(B_d)} = 0.993 \pm 0.009, \quad \frac{\tau(\Lambda_b)}{\tau(B_d)} = 0.930 \pm 0.020. \quad (1)$$

Nevertheless, better theoretical determinations of these quantities including other single-$b$ baryons are still highly desired in order to compete in precision with experimental measurements, as well as to test the validity of the Heavy Quark Expansion (HQE). Comparisons of HQE predictions and measurements of the lifetime ratios for different $b$-flavored hadrons are found in [4]. In particular, the dominant source of systematic uncertainties in predictions from the HQE is the unknown size of the matrix elements of $\Delta B = 0$ four-quark operators, and these can be determined from first principle calculations, i.e. lattice QCD simulations.

The theoretical calculation of the decay width can be done systematically using the optical theorem, which relates the total decay rate of the single-$b$ hadron $H_b$ to the imaginary part of the matrix element of the forward scattering amplitude,

$$\Gamma(H_b \to X) = \frac{1}{M_{H_b}} \text{Im}\langle H_b|T|H_b\rangle, \quad (2)$$

where $M_{H_b}$ is the hadron mass. Here the transition operator $T$ is given by

$$T = i \int d^4x T\{\mathcal{L}_{\text{eff}}(x), \mathcal{L}_{\text{eff}}(0)\}, \quad (3)$$

where $\mathcal{L}_{\text{eff}}$ represents the effective $\Delta B = 1$ weak Lagrangian renormalized at the scale of $b$-quark mass, $\mu = m_b$. Since the energy release is large ($\sim m_b$) in $b$-hadron decays, the operator product expansion (OPE) is applicable to construct local $\Delta B = 0$ operators having the same quantum numbers, with suppression by inverse powers of $m_b$ accompanying increasing operator dimensions. Using the OPE, one can write the decay width by

$$\Gamma(H_b \to X) = \frac{G_F^2 m_b^5}{192\pi^3} \frac{1}{2M_{H_b}} \sum_k \frac{c_k(\mu)}{m_{b}^{k-3}} \langle H_b|\mathcal{O}_{\Delta B=0}^{k}|H_b\rangle, \quad (4)$$

where $c_k(\mu)$ and $\mathcal{O}_{\Delta B=0}^{k}$ represent Wilson coefficients containing relevant CKM matrix elements and dimension-$k$ $\Delta B = 0$ local operators, respectively. The forward matrix elements
of the local operators in Eq. 4 are systematically expanded with inverse power of \( m_b \) in the framework of the HQE. In these expansions the leading-order term is universal for all kinds of \( b \) hadrons. It is well known that deviations of the lifetime ratios first arise from the terms of order \( 1/m_b^2 \) which include the nonperturbative corrections to \( \langle H_b|\bar{b}b|H_b \rangle \) in the HQE and the subleading terms in the OPE, \( \bar{b}g_s i\sigma_{\mu\nu}G^{\mu\nu}b \), whose dimension is five \([5–7]\). The spectator effects contribute to the process at the order of \( 1/m_b^3 \), where the corresponding dimension-six \( \Delta B = 0 \) four-quark operators in a convenient basis are given by \([1]\)

\[
\begin{align*}
O_{1,a} &= \bar{b}^\alpha \gamma_\mu (1 - \gamma_5) q^{a,\alpha} \bar{q}_a^\beta \gamma^\mu (1 - \gamma_5) b^\beta, \\
O_{2,a} &= \bar{b}^\alpha (1 - \gamma_5) q^{a,\alpha} \bar{q}_a^\beta (1 + \gamma_5) b^\beta, \\
O_{3,a} &= \bar{b}^\alpha \gamma_\mu (1 - \gamma_5) q^{a,\beta} \bar{q}_a^\alpha \gamma^\mu (1 - \gamma_5) b^\beta, \\
O_{4,a} &= \bar{b}^\alpha (1 - \gamma_5) q^{a,\beta} \bar{q}_a^\alpha (1 + \gamma_5) b^\beta,
\end{align*}
\]

where \( b \) denotes a \( b \)-quark field and \( q^a \) denotes a light-quark field of flavor \( a \). The color indices \( \alpha, \beta \) and the Lorentz indices \( \mu \) are summed, but the flavor indices \( a \) are not. In fact, although these effects are suppressed by an additional power of \( 1/m_b \), the contributions are numerically enhanced by a phase-space factor of \( 16\pi^2 \) relative to \( b \)-decays because of \( 2 \rightarrow 2 \) scatterings instead of \( 1 \rightarrow 3 \) decays \([1]\).

It was also pointed out that the contribution of the four-quark operators in Eq. 5 can be significant to the inclusive decay \( B \rightarrow X_u \ell\nu_\ell \) which is closely related to the determination of \( V_{ub} \) \([8]\). The four-quark operators relevant to this semi-leptonic decay are given by \( O_{1,u} - O_{2,u} \) at the scale \( \mu = m_b \) and their matrix elements can be parameterized by

\[
\frac{1}{M_B} (\langle B|O_{1,u}|B \rangle - \langle B|O_{2,u}|B \rangle) = f_B^2 M_B (B_1 - B_2),
\]

where \( f_B \) and \( M_B \) are the decay constant and the mass of \( B \) meson, respectively, and \( B_1 \) and \( B_2 \) are phenomenological parameters called bag constants. In the vacuum insertion approximation (or factorization) \([9, 10]\), we have \( B_1 = B_2 \) and the spectator effects in Eq. 6 vanish. However, the actual values of these matrix elements should be determined from non-perturbative calculations and can be much different than that from the factorization

---

1 For \( s_f = 0 \) single-\( b \) baryons, only the first two four-quark operators are sufficient to compute the spectator effects in the heavy-quark limit, because \( O_1 \) (\( O_2 \)) are related to \( O_3 \) (\( O_4 \)) up to \( 1/m_b \) corrections via a Fierz transformation thanks to heavy-quark symmetry.
approximation. In Ref. [8], for instance, the author showed that the correction to the branching ratio, $\delta B(B \to X_u \ell \nu_\ell)$, by spectator effects substantially enhances the estimate of the corresponding errors in the hybrid expansion, e.g. a violation of the relation $B_1 = B_2$ by 10% makes the correction of the branching ratio twice larger than the estimated uncertainty in Ref. [11].

In the OPE, the Wilson coefficients $c_k(\mu)$, which embed the dependence on scale $\mu$, are determined from perturbative calculations while the matrix elements of local four-quark operators can be computed nonpertubatively, potentially from lattice QCD (see Ref. [12] and references therein). From the point of view of lattice QCD, difficulties arise from the fact that the light quark of the operators $q$ can be different from the light valence-quark of the single-$b$ hadrons $q'$, i.e. $q$’s are contracted to themselves, so called “eye-contractions” [8]: the operators could mix with lower dimensional ones requiring a power-law subtraction. In addition, lattice calculations of the matrix elements including disconnected diagrams generally suffer from a noise problem. Although it is inevitable to avoid such difficulties in the calculation of the semi-leptonic decay, it is expected that the contributions of the eye-contractions are negligible in the calculation of the $B$-meson lifetime ratios due to the light-quark flavor symmetry. In particular, we find that the matrix elements of the $\lambda_3$ flavor-octet operators involving external $B_d$ meson, which are relevant to the determination of $\tau(B^+)/\tau(B_d)$, do not only exclude the eye-contractions, but also the disconnected contributions at the next-to-leading order in chiral expansion.

The purpose of this paper is to compute the one-loop chiral corrections, which are functions of light-quark mass (or pion mass), to the matrix elements of $\Delta B = 0$ four-quark operators in Eq. 5. At present, the light-quark masses in many lattice studies are not physical due to limited computing resources, and thus the chiral extrapolation to the physical quark masses is essential to obtain the matrix elements with high-precision. To do this, we consider heavy hadron chiral perturbation theory (HH$\chi$PT) [13–17] at finite volume [18–20] as the machinery to write the four-quark operators in terms of low-energy degrees of freedom, heavy hadrons and Goldstone mesons. Moreover, our calculation is performed in partially quenched chiral perturbation theory (PQ$\chi$PT) [21] which is appropriate for cur-

\footnote{More precisely, the “disconnected” means the flavor-disconnected in which the light-flavor quarks in the operators are not connected with those in the external hadrons. Throughout this paper, similarly, the “singlet” and “octet” mean the flavor-singlet and -octet, respectively.}
rent and foreseeable lattice calculations, as well as it naturally distinguishes disconnected diagrams from connected ones. Although the heavy quarks are assumed to be static, we consider the leading effect of various mass differences among $B$ mesons and single-$b$ baryons. For $B$ mesons, the chiral corrections to the matrix elements of infinite volume QCD were previously calculated in Ref. [22].

The organization of this paper is as follows. In Sec. II, we briefly review heavy hadron chiral perturbation theory involving hadrons containing a single-$b$ quark in SU(6|3) partially quenched theories. Mass differences in the heavy hadron spectrum, which originate from the light-quark flavor and heavy-quark spin symmetry breakings, are discussed in detail, where the relevant mass parameters enter the one-loop chiral computations. Sec. III contains the determination of $\Delta B = 0$ four-quark operators in partially quenched heavy hadron chiral perturbation theory. In Sec. IV we present our main results: calculation of the matrix elements of the four-quark operators including one-loop chiral contributions at infinite volume and in a finite spatial box, where connected and disconnected contributions are clearly separated. Integrals and sums appearing in the loop calculations are summarized in Appendix A while coefficients for these calculations involving $B$ mesons and single-$b$ baryons are summarized in Appendices B and C respectively. Moreover, the pion-mass dependence of chiral corrections and finite volume effects are discussed for the exemplified cases of external $B_d$, $B_s$ mesons and $\Lambda_b$ baryon. Finally, we conclude our work in Sec. V.

II. PARTIALLY QUENCHED HEAVY HADRON CHIRAL PERTURBATION THEORY

The interactions of heavy hadrons containing a heavy quark with Goldstone mesons can be described in the framework of chiral perturbation theory ($\chi$PT) combined with heavy quark effective theory (HQET). The inclusion of the heavy-light mesons into $\chi$PT was first carried out in [13–15] and extended to quenched and partially quenched theories in [23, 24]. The $1/M_P$ and chiral corrections were investigated in [25], where $M_P$ is the mass of the heavy-light pseudo-scalar meson. The “superfield” appearing in this effective theory is [26]

$$H_i^{(b)} = \left( P_{i,\mu}^{(h)} \gamma^\mu - P_i^{(b)} \gamma_5 \right) \frac{1 - \gamma'}{2}, \tag{7}$$
where $P_{i}^{(b)}$ and $P_{i,\mu}^{* (b)}$ annihilate pseudo-scalar and vector mesons containing an anti-$b$ quark and a light quark of flavor $i$. For convenience, the space-time variables in the fields and transformations do not explicitly appear throughout this paper (e.g. $H_{i}^{(b)}(x) = H_{i}^{(b)}$). In the heavy quark formalism, the momentum of such mesons is given as $p^\mu = M_P v^\mu + k^\mu$ with $k^\mu \ll M_P$, where $v^\mu$ is the 4-velocity of the meson fields. Under a heavy quark spin SU(2) transformation $S_h$ and a light-flavor transformation $U$ [i.e., $U \in SU(3)$ for full QCD and $U \in SU(6|3)$ for partially quenched QCD (PQQCD)], the field $H_{i}^{(b)}$ transforms as

$$H_{i}^{(b)} \rightarrow U_{j}^{i} H_{j}^{(b)} S_h^{-1}.$$  

The conjugate field, which creates mesons containing an anti-$b$ quark and a light quark of flavor $i$, is defined as

$$\bar{H}_{i}^{(b)} = \gamma^0 H_{i}^{(b)\dagger} \gamma_0 = \frac{1 - \gamma^\nu}{2} \left( P_{i,\mu}^{* (b)\dagger} \gamma_\mu + P_{i}^{(b)\dagger} \gamma_5 \right), \quad (8)$$

and transforms under $S_h$ and $U$ as

$$\bar{H}_{i}^{(b)} \rightarrow S_h \bar{H}_{j}^{(b)} U^{i}_{j}. \quad (9)$$

The inclusion of baryons containing a $b$-quark and two light quarks into \( \chi \)PT was first proposed in [15–17], and the effective theory was generalized to the quenched and partially quenched theories in [27–29]. In the limit $m_b \to \infty$, the heavy quark’s spin decouples from the system and the total spin of the light degrees of freedom is conserved. Because of this property of the heavy-quark symmetry, one can classify baryons by the total spin quantum number of the light degrees of freedom, $s_\ell = 0$ or $s_\ell = 1$. These two types of baryons carrying light flavors $i$ and $j$ can be included into SU(6|3) PQ\( \chi \)PT by introducing the corresponding interpolating fields at the quark level as

$$T_{ij}^\gamma \sim b^{\gamma, c} \left( q_{i}^{a,a} q_{j}^{b,b} + q_{i}^{b,b} q_{j}^{a,a} \right) \epsilon_{abc} (C\gamma_{5})_{\alpha\beta} \text{ for } s_\ell = 0,$$

$$S_{ij}^\gamma \sim b^{\gamma, c} \left( q_{i}^{a,a} q_{j}^{b,b} - q_{i}^{b,b} q_{j}^{a,a} \right) \epsilon_{abc} (C\gamma_{\mu})_{\alpha\beta} \text{ for } s_\ell = 1, \quad (10)$$

where $C$ is the charge-conjugation matrix, $\alpha, \beta, \gamma$ are the Dirac indices, and $a, b, c$ are color indices. These flavor tensor interpolating fields satisfy

$$T_{ij} = (-)^{n_i n_j} T_{ji}, \quad S_{ij}^{\mu} = (-1)^{1+n_i n_j} S_{ji}^{\mu}, \quad (11)$$
where the grading factor \( \eta_k \) accounts for different statistics of quarks in PQQCD,

\[
\eta_i = \begin{cases} 
1 & \text{for } k = 1, 2, 3, 4, 5, 6 \text{ (valence and sea)}, \\
0 & \text{for } k = 7, 8, 9 \text{ (ghost)}. 
\end{cases}
\]

(12)

The \( T \) and \( S \) fields form a 39- and a 42-dimensional representations of SU(6|3), respectively.

The baryon fields appearing in HH\( \chi \)PT have the same flavor properties of the corresponding interpolating fields as in Eq. (11) where the combination of the heavy-quark spin 1/2 and the total spin of light quarks \( s_\ell \) leads us that \( T \) baryon carries spin 1/2, while \( S \) baryon carries both spin 1/2 and 3/2 which are degenerate in the heavy-quark limit. If we restrict our attention to the pure valence-valence sector, we recover the familiar baryon tensors of QCD. For \( s_\ell = 0 \), the baryon tensor \( T^{(\text{valence-valence})}_{ij} \) is anti-symmetric under the exchange of light-quark flavor indices and explicitly written as

\[
T^{(\text{valence-valence})}_{ij} = \frac{1}{\sqrt{2}} \begin{pmatrix}
0 & \Lambda_b & \Xi^{+1/2}_b \\
-\Lambda_b & 0 & \Xi^{-1/2}_b \\
-\Xi^{+1/2}_b & -\Xi^{-1/2}_b & 0
\end{pmatrix},
\]

(13)

where the superscript indicates the 3-component of the isospin. For \( s_\ell = 1 \), the baryon tensor \( S^{ij}_{\mu} \) is described by the superfield

\[
S^{ij}_{\mu} = \sqrt{\frac{1}{3}} (\gamma_\mu + v_\mu) \gamma^5 B^{ij} + B^{*ij}_{\mu},
\]

(14)

where \( B_{ij} \) and \( B^{*\mu}_{ij} \) are spin-1/2 and 3/2 baryons, respectively.\(^3\) In the valence-valence sector, the baryon tensor \( B^{(\text{valence-valence})}_{ij} \) is symmetric under the exchange of light-quark flavor indices and explicitly written as

\[
B^{(\text{valence-valence})}_{ij} = \begin{pmatrix}
\Sigma^0_b & \frac{1}{\sqrt{2}} \Sigma^0_b & \frac{1}{\sqrt{2}} \Xi^{+1/2}_b \\
\frac{1}{\sqrt{2}} \Sigma^0_b & \Sigma^{-1}_b & \frac{1}{\sqrt{2}} \Xi^{-1/2}_b \\
\frac{1}{\sqrt{2}} \Xi^{+1/2}_b & \frac{1}{\sqrt{2}} \Xi^{-1/2}_b & \Omega_b
\end{pmatrix},
\]

(15)

and similarly for the \( B^{*\mu}_{ij} \) fields. Under the heavy-quark spin transformation \( S_h \) and the light-flavor transformation \( U \),

\[
T_{ij} \rightarrow S_h U^{k}_i U^{k}_j T_{kl}, \\
S^{\mu}_{ij} \rightarrow S_h U^{k}_i U^{k}_j S^{\mu}_{kl}.
\]

(16)

\(^3\) The baryon field \( T_{ij} (B_{ij}) \) satisfies \( \frac{1}{2} \gamma^\mu T_{ij} (B_{ij}) = T_{ij} (B_{ij}) \), while \( B^{*\mu}_{ij} \) satisfies \( \frac{1}{2} \gamma^\mu B^{*\mu}_{ij} = B^{*\mu}_{ij} \) and \( \gamma^\mu B^{*\mu}_\mu = 0 \).
The conjugate fields, which create single- \( b \) baryons, are denoted as \( \bar{S}_{ij}^\mu \) and \( \bar{T}_{ij}^\mu \).

In PQ\( \chi \)PT, the leading-order (LO) chiral Lagrangian for the Goldstone mesons is

\[
\mathcal{L} = \frac{f^2}{8} \text{str}[(\partial^\mu \Sigma^\dagger)(\partial_\mu \Sigma) + 2B_0(\Sigma^\dagger \mathcal{M}_q + \mathcal{M}^\dagger_q \Sigma)] + \alpha_\pi(\partial^\mu \Phi_0)(\partial_\mu \Phi_0) - M_0^2 \Phi_0^2, \tag{17}
\]

where \( \Sigma = \exp(2i\Phi/f) = \xi^2 \) is the nonlinear Goldstone field, with \( \Phi \) being the matrix containing the standard Goldstone fields in the quark-flavor basis. In this work, we follow the supersymmetric formation of PQ\( \chi \)PT where the flavor group is graded \[21\]. Therefore \( \Sigma \) transforms linearly under \( SU(6|3)_L \otimes SU(6|3)_R \),

\[
\Sigma \rightarrow U_L \Sigma U_R^\dagger, \tag{18}
\]

where \( U_{L(R)} \in SU(6|3)_{L(R)} \) is the left-handed (right-handed) light-flavor transformation. The operation \( \text{str}[\ ] \) means “supertrace” over the graded light-flavor indices. The low-energy constant \( B_0 \) is related to the chiral condensate by

\[
B_0 = -\frac{\langle 0|\bar{u}u + \bar{d}d|0 \rangle}{f^2}, \tag{19}
\]

and the quark-mass matrix in the isospin limit is

\[
\mathcal{M}_q = \text{diag}(m_u, m_u, m_s, m_j, m_j, m_r, m_u, m_u, m_s). \tag{20}
\]

We keep the strange quark mass different from that of the up and down quarks in the valence, sea, and ghost sectors. Analogous to QCD, the strong U(1)\( A \) anomaly can give rise to the large mass of the singlet field \( \Phi_0 = \text{str}(\Phi)/\sqrt{6} \), i.e. same size of the chiral symmetry breaking scale, and thus \( \Phi_0 \) can be integrated out, resulting in residual hairpin structures in the two-point correlation function of neutral mesons \[30, 31\].

The Goldstone mesons couple to the above \( B \) meson and single- \( b \) baryon fields via the field \( \xi \), which transforms as

\[
\xi \rightarrow U_L \xi U_R^\dagger = U \xi U_R^\dagger, \tag{21}
\]

where \( U \) is a function of \( U_L, U_R, \) and \( \Phi \). The field \( \xi \) can be used to construct the vector and axial-vector fields of meson,

\[
V^\mu = \frac{i}{2}[\xi^\dagger \partial^\mu \xi + \xi \partial^\mu \xi^\dagger], \quad A^\mu = \frac{i}{2}[\xi^\dagger \partial^\mu \xi - \xi \partial^\mu \xi^\dagger]. \tag{22}
\]
As the vector field plays a role similar to a gauge field, the chiral covariant derivatives which act on $B$ meson and single-$b$ baryon fields can be defined as
\[
D^\mu H_i^{(b)} = \partial^\mu H_i^{(b)} - i(V^\mu)_{ij} H_j^{(b)},
\]
\[
D^\mu T_{ij} = \partial^\mu T_{ij} - i(V^\mu)_{ik} T_{kj} - i(-1)^{\eta_i(\eta_j + \eta_k)} (V^\mu)_{ij} T_{ik},
\]
\[
D^\mu S^\nu_{ij} = \partial^\mu S^\nu_{ij} - i(V^\nu)_{ik} S^\nu_{kj} - i(-1)^{\eta_i(\eta_j + \eta_k)} (V^\nu)_{ij} S^\nu_{ik},
\]
The LO effective Lagrangian in the chiral and $1/M_B$ expansions is
\[
L^{(\text{LO})}_{\text{HH\chiPT}} = -itr_{D}[\bar{H}^{(b)}_i v \cdot D H_i^{(b)}] - i(\bar{S}^\mu v \cdot D S_\mu) + i(\bar{T} v \cdot D T) + \Delta^{(B)}(\bar{S}^\mu S_\mu)
\]
\[
 + g_1 tr_{D}[H_i^{(b)} \bar{H}^{(b)j} \gamma_\mu \gamma_5 A^{\mu,i}] + ig_2 \epsilon_{\mu\nu\sigma\rho}(\bar{S}^\mu v_\nu A^\sigma S^\rho) + \sqrt{2} g_3 \left[ (\bar{T} A^\mu S_\mu) + (\bar{S}^\mu A_\mu T) \right],
\]
where $\text{tr}_D$ is the trace over Dirac space and $v_\mu$ is the velocity of the heavy hadrons. Note that the $B$-meson fields are of mass dimension $3/2$ like the single-$b$ baryon fields by absorbing $\sqrt{M_B}$ into $H_i^{(b)}$, where $M_B$ is the mass of the $B$ meson. The flavor index contractions of the operators for the baryons are
\[
(\bar{T} Y T) = \bar{T}_{ij} Y_{ij} T_{ij},
\]
\[
(\bar{S}^\mu Y S_\mu) = \bar{S}^{\mu,ij} Y^{ij} S_{\mu,ij},
\]
\[
(\bar{T} Y^\mu S_\mu) = \bar{T}^{\mu,ij} Y^{\mu,ij} S_{\mu,ij}.
\]
The parameter $\Delta^{(B)}$ is the mass difference between the $S$ and $T$ fields with same light flavor indices,
\[
\Delta^{(B)} = M_S - M_T,
\]
which is of $O(\Lambda_{\text{QCD}})$ and does not vanish either in the chiral limit or in the heavy-quark limit.

In one-loop chiral calculations, the effects of SU(6)$|3$ flavor symmetry breaking appear through the mass differences of hadron fields:
\[
L^{(\chi)}_{\text{HH\chiPT}} = \tilde{\lambda}_1 \text{tr}_D[H_i^{(b)} M_{\xi,j} H^{(b)j}] + \lambda_1^{ij} \text{tr}_D[H_i^{(b)} H^{(b)j}] \text{str}(M_\xi)
\]
\[
 + \tilde{\lambda}_2 (\bar{S}^\mu M_\xi S_\mu) + \lambda_2^{ij} (\bar{S}_\mu S_\mu) \text{str}(M_\xi) + \tilde{\lambda}_3 (\bar{T} M_\xi T) + \lambda_3^{ij} (\bar{T} T) \text{str}(M_\xi),
\]
where
\[
M_\xi = B_0 \left( \bar{\xi} M_{\xi}^{\dagger} \xi + \xi^{\dagger} M_{\xi}^\dagger \right).
\]
The terms proportional to $\lambda'$ cause a universal shift to the single-$b$ hadron masses, while the terms proportional to $\tilde{\lambda}$ attribute to the mass differences,

$$\delta_{i,j}^{(M)} = M_{B_j} - M_{B_i} = M_{B_j'} - M_{B_i'} = 2\tilde{\lambda}_1 B_0 (m_j - m_i),$$

$$\delta_{i,j}^{(B)} = M_{T_{i,s}} - M_{T_{i,s}} = M_{S_{j,s}} - M_{S_{i,s}} = 2\tilde{\lambda}_2 B_0 (m_j - m_i),$$

(28)

where $s$ represents the spectator quark and we assume $\tilde{\lambda}_2 = \tilde{\lambda}_3$. We also consider the effects of heavy-quark spin symmetry breaking at $O(\Lambda_{QCD}/m_Q)$,

$$\frac{\alpha}{m_b} \text{tr}_D \left( H^{(b)}_a \sigma_{\mu\nu} H^{(b),a}_{\sigma\mu\nu} \right),$$

(29)

which vanishes in the heavy-quark limit. The $\alpha$ term provides the mass difference between the $B^*$ and $B$ mesons with same light flavor,

$$\Delta^{(M)} = M_{B^*_i} - M_{B_i} = -8\frac{\alpha}{m_b}.\,$$

(30)

In principle, there are also analogous heavy-quark spin symmetry breaking terms in the baryon sector, resulting in mass differences between $B_{ij}$ and $B_{ij}^*\mu$ baryons in Eq. 14. However, we neglect these mass differences which are numerically much smaller than $\Delta^{(B)}$. If we redefine the field in which the heavy-light meson and $T$ baryon containing $u$ or $d$ valence quarks are massless, the denominators of the propagators for other heavy-light mesons and single-$b$ baryons are shifted by the linear combinations of various mass differences in Eq. 25, Eq. 28 and Eq. 30.

III. $\Delta B = 0$ FOUR-QUARK OPERATORS IN HEAVY HADRON CHIRAL PERTURBATION THEORY

In the partially quenched theory, the four-quark operators in Eq. 5 transform as left-flavor singlet, a 30-dimensional representation, and left-flavor octet, a 51-dimensional representation, built form the tensor product of two fundamental representations of SU(6|3). For lattice QCD, a more convenient form of the $\Delta B = 0$ four-quark operators can be obtained
by accounting for the graded light-flavor transformations:

\[
\mathcal{O}_k^{\text{PQ}} = \text{str} \left( \lambda_k^{\text{PQ}} \mathcal{O} \right) + \delta^{\text{eye}} \text{str} \left( \lambda_k^{\text{PQ}} \right) \text{str} \left( \mathcal{O} \right),
\]

with

\[
\mathcal{O}_a^b = \bar{b} \Gamma^{(1)} q_L^a \bar{q}_{L,b} \Gamma^{(2)} b,
\]

where

\[
q_L^a = \frac{1 - \gamma_5}{2} q^a, \quad \bar{q}_{L,b} = \bar{q}_b^1 + \gamma_5 \frac{1 + \gamma_5}{2}.
\]

Here \( \Gamma^{(1)} \) and \( \Gamma^{(2)} \) are the appropriate spin and color matrices. Following the standard construction of the operators from heavy hadron fields, we can consider \( \Gamma^{(1)} \) and \( \Gamma^{(2)} \) as spurious fields. To make the operators invariant under SU(2) heavy-quark spin and SU(6|3) flavor transformations, the spurious fields must transform as

\[
\Gamma^{(1)} \rightarrow S_h \Gamma^{(1)} U_L^\dagger, \quad \Gamma^{(2)} \rightarrow U_L \Gamma^{(2)} S_h^\dagger.
\]

The symbol “\( \delta^{\text{eye}} \)” denotes the contribution of the eye-contractions, where the light quarks in the four-quark operators \( \mathcal{O} \) are contracted by themselves, while the symbol “\( \lambda^{\text{PQ}} \)” denotes the partially-quenched extension of the Gell-Mann matrix. It is convenient to classify the operators according to three types of quarks, (valence, sea, ghost), transform under the chiral rotation of SU(3)\(_{\text{val}}\) \( \otimes \) SU(3)\(_{\text{sea}}\) \( \otimes \) SU(3)\(_{\text{ghost}}\); the Gell-Mann matrices can be extended in a simple way, \( \lambda_k^{\text{PQ}} = \lambda_k \otimes \text{diag}(1, \lambda_{\text{sea}}, 1) \), where \( \lambda_0 = \text{diag}(1, 1, 1) \) for the flavor-singlet and \( \lambda_3 = \text{diag}(1, -1, 0) \), \( \lambda_8 = \text{diag}(1, 1, -2) \) for the flavor-octet. Here, we introduce “\( \lambda_{\text{sea}} \)” to distinguish the disconnected (non-valence) contributions from the connected (valence) ones, i.e. \( \lambda_{\text{sea}} = 1 \) or \( \lambda_{\text{sea}} = 0 \) depending whether the disconnected contributions are included or not.

The LO operators in HH\( \chi \)PT relevant to the four-quark operators in Eq.\(^{32} \) can be written as

\[
\mathcal{O}_{\text{HH}\chi\text{PT}}^{(\text{LO}),\lambda_k^{\text{PQ}}} = \text{str} \left( \lambda_k^{\text{PQ}} \mathcal{O} \right) + \delta^{\text{eye}} \text{str} \left( \lambda_k^{\text{PQ}} \right) \text{str} \left( \mathcal{O}^{\text{bare}} \right),
\]

\(^4\) In SU(\( K + N | K \)) PQQCD with arbitrary \( K \) (valence and ghost quarks) and \( N \) (sea quarks), the singlet four-quark operators do not match those of unquenched QCD\(^{34} \). When the number of valence quarks is equal to the number of sea quarks (i.e \( K = N = 3 \) in our case), however, this mismatch disappears and the LO low-energy constants appearing in both theories are exactly same.
where the tilded operators $\tilde{O}_{\mathrm{HM}}^b$ for heavy-light mesons and $\tilde{O}_{\mathrm{HB}}^b$ for single-$b$ baryons are defined in below Sec. [III.A] and Sec. [III.B] respectively. At the tree level in the chiral expansion, the first term corresponds to connected diagrams, while the second term corresponds to disconnected diagrams which are absent for the octet. Notice that, as will be seen in Sec. [IV] the first term generates disconnected diagrams as well as connected ones at the NLO one-loop level.

A. $\Delta B = 0$ four quark operators for heavy-light $B$-mesons

The most general bosonized form of the four-quark operators for heavy-light $B$-mesons in $\chi$PT is\(^6\)

$$
\left(\tilde{O}_{\mathrm{HM}}^b\right)_a^b = \sum_x \left\{ \alpha_{i,x}^{(1)}((\xi \tilde{H}^{(b)})a \Gamma^{(1)}\Xi_x)[\Gamma^{(2)}(H^{(b)}\xi^\dagger)_b \Xi'_x] + \alpha_{i,x}^{(2)}((\xi \tilde{H}^{(b)})a \Gamma^{(1)}\Xi_x)[\Gamma^{(2)}(H^{(b)}\xi^\dagger)_b \Xi'_x]ight.
$$

$$
+ \alpha_{i,x}^{(3)}((\xi \tilde{H}^{(b)})a \Gamma^{(1)}\Xi_x)[\Gamma^{(2)}(H^{(b)}\xi^\dagger)_b \Xi'_x] + \alpha_{i,x}^{(4)}((\xi \tilde{H}^{(b)})a \Gamma^{(1)}\Xi_x)[\Gamma^{(2)}(H^{(b)}\xi^\dagger)_b \Xi'_x]
$$

$$
+ \alpha_{i,x}^{(5)}((\xi \tilde{H}^{(b)})a (H^{(b)}\xi^\dagger)_b \Xi_x)[\Gamma^{(2)}\Gamma^{(1)}\Xi'_x] + \alpha_{i,x}^{(6)}((\xi \tilde{H}^{(b)})a (H^{(b)}\xi^\dagger)_b \Xi_x)[\Gamma^{(2)}\Gamma^{(1)}\Xi'_x]
$$

$$
+ \alpha_{i,x}^{(7)}((\xi \tilde{H}^{(b)})a (H^{(b)}\xi^\dagger)_b \Xi'_x)[\Gamma^{(2)}\Gamma^{(1)}\Xi'_x] + \alpha_{i,x}^{(8)}((\xi \tilde{H}^{(b)})a (H^{(b)}\xi^\dagger)_b \Xi'_x)[\Gamma^{(2)}\Gamma^{(1)}\Xi'_x]\right\},
$$

where $i = 1, 2, 3, 4$, and $\Xi_x$ are $\Xi'_x$ are all possible pairs of Dirac structures.\(^7\) The bracket notation $[\cdot]$ represents the trace over the Dirac space. Any insertion of $\gamma$ in the Dirac structures can be absorbed by the heavy meson fields, $\gamma H(v) = H(v)$, while any insertion of $\gamma_5$ at most changes the sign of $\Gamma$. The HQET parity conservation and the contraction of Lorentz indices requires that $\Xi_x = \Xi'_x$. The single Dirac-trace terms can be rewritten by the double trace using the $4 \times 4$ matrix identity

$$
4[AB] = [A][B] + [\gamma_5 A][\gamma_5 B] + [A\gamma_\mu][\gamma^\mu B] + [A\gamma_\mu\gamma_5][\gamma_5\gamma^\mu B] + \frac{1}{2}[A\sigma_{\mu\nu}][\sigma^{\mu\nu}].
$$

\(^5\) The operator $\tilde{O}_{\mathrm{bare}}^{(\mathrm{bare})}$ is the tree-level operator of $\tilde{O}$, i.e. the four-quark operators are not dressed by Goldstone mesons.

\(^6\) The field $H_i^{(b)}$ for mesons containing a $b$ quark and a light anti-quark of flavor $i$ is obtained by applying the charge conjugation operation to the field $H_i^{(b)}$ in Eq. [36]; $H_i^{(b)} = \frac{1}{2} P_i^{*(\mu)}(P_i^{(\mu)} - P_{(b)}^{(\mu)})$, which transforms under $S_b$ and $U$ as $H_i^{(b)} \rightarrow S_b H_i^{(b)} U^{T_i}$. Also, the conjugate field is defined as $H_i^{(b)\dagger} = \gamma^0 H_i^{(b)}\gamma^0$.

\(^7\) The Dirac structure $\Xi_x = 1, \gamma_\mu, \sigma_{\mu\nu}$, and possible combinations with $\gamma$ and $\gamma_5$. 

12
Since $\Gamma^{(1)}$ and $\Gamma^{(2)}$ are left- and right-handed current respectively, the last four terms in Eq. 36 vanish. In summary, the operators in $\tilde{O}^{\text{HM}}_i$ can be reduced to

$$
(\tilde{O}^{\text{HM}}_i)_a^b = \sum_x \left\{ \bar{\alpha}_{i,x} \left[ (\xi H^{(b)})^a \Gamma^{(1)} \Xi \right] \left[ (H^{(b)})^{\dagger} \xi^\dagger \right] \right\} + \alpha_{i,x} \left[ (\xi H^{(b)})^a \Gamma^{(1)} \Xi \right] \left[ (H^{(b)})^{\dagger} \xi^\dagger \right] \Xi \right\}, 
$$

(38)

where $\Xi \in \{1, \gamma_\nu, \sigma_{\nu\rho}\}$ and the bracket $[\ ]$ denotes the trace over the Dirac space. After evaluating the trace, we obtain

$$
(\tilde{O}^{\text{HM}}_i)_a^b = \bar{\beta}_{i,1} (\xi P^{(b)^\dagger})^a (P^{(b)^\dagger} \xi^\dagger)_b + \bar{\beta}_{i,2} (\xi P^{(b)^\dagger})^a (P^{(b)^\dagger,\mu} \xi^\dagger)_b + \beta_{i,1} (\xi P^{(b)^\dagger})^a (P^{(b)^\dagger,\xi^\dagger} \xi^\dagger)_b, 
$$

(39)

where $\beta$ and $\bar{\beta}$ are linear combinations of $\alpha_{i,x}$ and $\bar{\alpha}_{i,x}$, respectively. Explicitly we have, for $i = 1, 3$,

$$
\beta_{i,1} (\bar{\beta}_{i,1}) = 4 \alpha_{i,1} (\bar{\alpha}_{i,1}) + 16 \alpha_{i,\gamma_\nu} (\bar{\alpha}_{i,\gamma_\nu}), \\
\beta_{i,2} (\bar{\beta}_{i,2}) = 4 \alpha_{i,1} (\bar{\alpha}_{i,1}), 
$$

(40)

for $i = 2, 4$

$$
\beta_{i,1} (\bar{\beta}_{i,1}) = 4 \alpha_{i,1} (\bar{\alpha}_{i,1}) + 4 \alpha_{i,\gamma_\nu} (\bar{\alpha}_{i,\gamma_\nu}), \\
\beta_{i,2} (\bar{\beta}_{i,2}) = 4 \alpha_{i,\gamma_\nu} (\bar{\alpha}_{i,\gamma_\nu}). 
$$

(41)

As shown above, the low-energy constants (LECs) for pseudo-scalar and vector meson mixing processes are different in all cases, which is different from the results in Ref. [22] where LECs for the case of $i = 2, 4$ are same. Since having a single LEC for the operators in an effective theory greatly simplifies chiral extrapolation of corresponding lattice data, it is important to confirm our result from another consideration. For this purpose, consider our four-fermion operators, $O_{i,a}$, which appear in HQET [35][37] as,

$$
O^{\text{HQET}}_{i,a} = Q \Gamma^{(1)} q_a q_a (H^{(b)})^a + \bar{Q} \Gamma^{(1)} q_a q_a (H^{(b)})^a, 
$$

(42)

where $\Gamma$ are the appropriate Dirac and color structures, while $Q$ and $\bar{Q}$ are the fields annihilating a heavy quark and heavy anti-quark, respectively. Note that these fields do not create the corresponding anti particles but their conjugate fields do.
We also consider the heavy quark spin operator \[ S^3_Q = \epsilon^{ij3}[Q^i\sigma_{ij}Q - \bar{Q}\sigma_{ij}\bar{Q}^i], \] where \( \sigma_{ij} = \frac{i}{2}[\gamma_i, \gamma_j] \) with \( i, j = 1, 2, 3 \). Since the heavy quark spin operator changes the spin of heavy-light meson by one, the relation between LECs in the operator \( \tilde{O}^\text{HM}_i \) can be seen from calculating the commutation (or anti-commutation) of \( S^3_Q \) and \( \tilde{O}^\text{HQET}_{i,0} \) acting on the pseudo-scalar heavy-light meson state \( |P\rangle \) containing a heavy-quark field \( Q \). We find that

\[ [S^3_Q, \tilde{O}^\text{HQET}_{i,0}]|P\rangle \neq 0, \quad \{S^3_Q, \tilde{O}^\text{HQET}_{i,0}\}|P\rangle \neq 0. \] Similar results can be shown for the pseudo-scalar heavy-light meson state \( |\tilde{P}\rangle \) containing a heavy anti-quark field \( \bar{Q} \). This implies that the pseudo-scalar and vector meson mixing processes via these operators are not simply related to each other, and so they are accompanied by different LECs consistent with Eq. \[39\]

**B. \( \Delta B = 0 \) four quark operators for single-b baryons**

The most generalized form of four-quark operators for single-b baryons in HHQ\( \chi \)PT is

\[
\left( \tilde{O}^\text{HB}_i \right)^{a}_{b} = \sum_x \left\{ \alpha^{(1)}_{i,x}(S_\mu \xi^\dagger)^{ak}\Gamma^{(1)}\Xi^{(2)}(\xi S_\nu)_{bk} + \alpha^{(2)}_{i,x}(S_\mu \xi^\dagger)^{ak}\xi S_\nu \right\} tr_D[\Gamma^{(1)}\Xi^{(2)}] \\
+ \alpha^{(3)}_{i,x}(\bar{T}\xi^\dagger)^{ak}\Gamma^{(1)}\Xi^{(2)}(\bar{T}\xi)_{bk} + \alpha^{(4)}_{i,x}(\bar{T}\xi^\dagger)^{ak}\xi S_\nu \right\} tr_D[\Gamma^{(1)}\Xi^{(2)}],
\]

where \( i = 1, 2, 3, 4 \), and \( \Xi \) and \( \Xi^{\mu\nu} \) are all possible Dirac structures,

\[
\Xi = 1, \quad \gamma^\mu, \quad \Xi^{\mu\nu} = \gamma^\mu, \quad \gamma^\mu \gamma^\nu, \quad \gamma^\mu \gamma^\nu, \quad \gamma^\mu \gamma^\nu, \quad \gamma^\mu \gamma^\nu
\]

and possible combinations with \( \gamma^5 \). Any insertion of \( \gamma^5 \) changes at most the overall sign. One may consider the terms \( \bar{T}\Gamma^{(1)}\Xi^{(2)} S_\mu \) and \( \bar{T}\Gamma^{(1)}\Xi^{(2)} S_\mu \) along with their conjugates which are invariant under SU(2) heavy quark spin symmetry, where \( \Xi^{\mu} = \gamma^\mu, \quad \gamma^\mu \gamma^\nu, \quad \gamma^\mu \gamma^\nu, \quad \gamma^\mu \gamma^\nu, \quad \gamma^\mu \gamma^\nu, \quad \gamma^\mu \gamma^\nu \)

However, we exclude these terms because, along with \( \lambda^{PQ} \), they violate the SU(6|3)_{L+R} flavor symmetry. By evaluating the Dirac matrices we obtain

\[
\left( \tilde{O}^\text{HB}_i \right)^{a}_{b} = \left\{ \beta'_{i,1}(\bar{B}\xi^\dagger)^{ak}(\xi B)_{bk} + \beta'_{i,2}(\bar{B}\xi^\dagger)^{ak}(\xi B^*\mu)_{bk} + \beta'_{i,3}(\bar{T}\xi^\dagger)^{ak}(\xi T)_{bk} \right\},
\]

where \( \beta' \)'s are linear combinations of \( \alpha' \)'s. The explicit values of \( \beta' \)'s are, for \( i = 1, 3 \),

\[
\beta'_{i,1} = 4\alpha^{(1)}_{i,1} y^\mu_{\nu} - 8i(\alpha^{(1)}_{i,1} y^\mu_{\nu} + \alpha^{(1)}_{i,\sigma_{\mu}\nu} y^\sigma), \quad \beta'_{i,2} = -\frac{1}{2}\beta'_{i,1} - 2\alpha^{(1)}_{i,1} y^\mu_{\nu}, \quad \beta'_{i,3} = -4\alpha^{(3)}_{i,1} y^\nu
\]
and for $i = 2, 4$,

$$
\beta'_{i,1} = -2\alpha_i^{(1)} \eta_i \eta_{I} \gamma_{\mu} - 4i(\alpha_i^{(1)} \eta_i \gamma_{\mu} + \alpha_i^{(1)} \eta_{I} \gamma_{\mu}), \quad \beta'_{i,2} = \frac{1}{2} \beta'_{i,1} + 3\alpha_i^{(1)} \eta_i \eta_{I} \gamma_{\mu}, \quad \beta'_{i,3} = 2\alpha_i^{(3)} \eta_i \eta_{I} \gamma_{\mu}.
$$

Unfortunately, this result implies that none of the low-energy constants are related to each other, and thus all of them must be considered as independent parameters in fitting lattice QCD data.

### IV. MATRIX ELEMENTS OF $\Delta B = 0$ OPERATORS

The generic forms of the matrix elements of $\Delta B = 0$ four-quark operators in SU$(6|3)$ partially quenched HH$\chi$PT can be written as

$$
\langle B|\mathcal{O}_{k}^{\lambda_{PQ}}|B\rangle = (1 + 3\lambda_{\text{sea}}\delta_{I}\delta_{K}) \left[ C_{M}^{k}\beta_{1}(1 + W_{B}) + \beta_{2}Q_{B}^{k} \right] + \beta_{1}T_{B}^{k} + \text{analytical terms},
$$

for $B$ mesons\(^8\) and

$$
\langle T|\mathcal{O}_{k}^{\lambda_{PQ}}|T\rangle = (1 + 3\lambda_{\text{sea}}\delta_{I}\delta_{K}) \left[ C_{T}^{k}\beta_{1}(1 + W_{T}) + (-\beta'_{1} + 2\beta'_{2})Q_{T}^{k} \right] + \beta_{1}T_{T}^{k} + \text{analytical terms},
$$

$$
\langle S|\mathcal{O}_{k}^{\lambda_{PQ}}|S\rangle = (1 + 3\lambda_{\text{sea}}\delta_{I}\delta_{K}) \left[ C_{S}^{k}\beta_{1}(1 + W_{S}) + (-2\beta'_{1} + \beta'_{2})Q_{S}^{k} + \beta'_{3}Q_{S}^{k} \right] + \beta_{1}T_{S}^{k} + \text{analytical terms},
$$

for $T$ and $S$ baryons. The equality symbol means the matching between PQQCD and the chiral effective theory. The coefficients $C_{M}^{0} = C_{T}^{0} = C_{S}^{0} = 1$ for all external single-$b$ hadrons.

\(^8\) More precisely, $|B\rangle$ denotes the state annihilating a $B$ meson containing a anti-$b$ quark and a light quark, where we use the standard notation, e.g. $B_{u} = B^{+} = \bar{b}u$. It is straightforward to extend our calculations to the $\Delta B = 0$ matrix elements involving mesons containing a $b$ quark and a light antiquark.
TABLE II: Coefficients $C^k_T$ and $C^k_S$ in Eq. 51

|         | $C^k_T$          |         | $C^k_S$          |
|---------|------------------|---------|------------------|
| $\Lambda_b$ | $\Xi^+_b$ $\Xi^+_b$ | $\Sigma^0_b$ $\Sigma^+_b$ $\Sigma^-_b$ | $\Xi^{'+1/2}_b$ $\Xi^{'+1/2}_b$ $\Omega_b$ |
| $k = 3$ | 0 $\frac{1}{2}$ $\frac{1}{2}$ | 0 1 $-1$ $\frac{1}{2}$ $-\frac{1}{2}$ 0 |
| $k = 8$ | 1 $-\frac{1}{2}$ $-\frac{1}{2}$ | 1 1 1 $-\frac{1}{2}$ $-\frac{1}{2}$ $-2$ |
sion, in particular, the former contributions play a role of counterterms which are necessary to renormalize the one-loop contributions. There are five corresponding NLO operators, \( \text{str}(\lambda \rho Q M \hat{O}) \), \( \text{str}(\lambda \rho Q \hat{O}) \), \( \text{str}(\lambda \rho Q \hat{O} M \xi) \), \( \text{str}(\lambda \rho Q \hat{O} M \xi) \), and \( \text{str}(\lambda \rho Q \hat{O} M \xi) \), accompanying with unknown low-energy constants. Notice that in the isospin and QCD limit the last three operators for \( \lambda \rho Q \) vanish, while those for \( \lambda \rho Q \) are proportional to \( m_K^2 - m_\pi^2 \) originate from the flavor SU(3) symmetry breaking.

A. One-loop contributions for \( B \) Meson

First, we study the one-loop contributions for \( B \) mesons in Eq. 50. To take account of the flavor SU(3) breaking effects from both the Goldstone masses and the heavy-meson spectrum, we investigate the structure of the one-loop diagrams by analyzing the quark-flavor flow picture [39]. To do this, we define the rules as below.

- Each flavor flow line in a one-loop diagram has a direction and a flavor index: the flow along the direction means a quark with that flavor, while the flow against the direction means its antiquark. We drop the flavor index of a \( b \)-quark because of its irrelevance to our discussion.

- The “tilded” coefficients are for the hairpin contributions from the flavor-neutral mesons.

- The “bar” notation in the coefficients denotes the flavor-disconnected diagrams appearing in the chiral expansion, which are distinguished from the eye-contraction in Eq. 35.

Following the above rules and the quark flow picture in Fig. 2, the wave-function renormalization contributions can be written as [19]

\[
W_{B_a} = \frac{i g_1^2}{f^2} \left[ 6 \mathcal{H}(M_{a,j}, \Delta^{(M)} + \delta_{a,j}^{(M)}) + 3 \mathcal{H}(M_{a,r}, \Delta^{(M)} + \delta_{a,r}^{(M)}) - \tilde{\mathcal{H}}(M_{a,a}, \Delta^{(M)}) \right],
\]  

(52)

where \( a \) runs over the valence light-quark flavors. The non-analytic functions \( \mathcal{H} \) and \( \tilde{\mathcal{H}} \) are defined in the Appendix A, while the mass parameters \( M_{a,b} \), \( \Delta^{(M)} \) and \( \delta_{a,b}^{(M)} \) are defined in Sec. II.
FIG. 2: Self-energy diagrams contributing to the matrix elements containing $B$ mesons. The solid thick and thin lines denote the anti-$b$ quark and the valence light quark, respectively, while the dashed thin line denotes the sea light quark. Diagram (b) is the hairpin structure.

FIG. 3: Sunset diagrams contributing to the matrix elements containing $B$ mesons. The solid thick and thin lines denote the anti-$b$ quark and the valence light quark, respectively. The crossed square is the four-quark operator $O^{\lambda PQ}_{\kappa}$. Diagram (b) is the hairpin structure.

The loop contributions for tadpole integrals are completely determined by the structure of the four-quark operators in Eq. 39 where the flavor SU(3) breaking effects arise solely from the Goldstone masses. As a result, we obtain

$$T_B^k = \frac{i}{f^2} \sum_{\phi} (x^{B,k}_{\phi_{ab}} + \lambda^{sea} x^{R,k}_{\phi_{ab}}) \mathcal{I}(M_{a,b}),$$

where the summation runs over all possible Goldstone mesons in SU(6|3) PQ$\chi$PT. The non-analytic function $I$ is defined in Appendix A and the coefficients $x$ and $\bar{x}$ are given in Table III in Appendix B. Notice that all hairpin diagrams cancel out and do not contribute to any one-loop tadpole corrections.

The quark flow picture for sunset diagrams is presented in Fig. 3 where the crossed square represents the four-quark operator $O^{\lambda PQ}_{\kappa}$ including both the eye- and noneye-contraction in Eq. 35. The hairpin diagrams for the noneye-contraction give rise to the connected contribution, while the others give rise to the disconnected contribution. The contributions
from the sunset diagrams are then summarized as

$$Q_k^B = \frac{i g_1^2}{f^2} \sum_\phi \lambda^{sea} y_{\phi_{ab}}^B k H(M_{a,b}, \Delta^{(M)} + \delta_{a,b}^{(M)}) - \sum_{\phi'_{a,b}} \tilde{y}_{\phi_{ab}}^B k \tilde{H}(M_{a,b}, \Delta^{(M)})$$,

(54)

where the second term sums over all pairs of flavor-neutral states in the valence-valence sector, i.e. $\phi\phi'$ runs over $\eta_u\eta_u, \eta_u\eta_s$, and $\eta_s\eta_s$. The coefficients are given in Table IV in Appendix B.

**B. One-loop contributions for single-$b$ Baryon**

To discuss the structure of the single-$b$ baryon one-loop diagrams within the quark-flavor flow picture, we introduce one more rule:

- The “primed” coefficients are for the one-loop diagrams involving the internal $T$ baryon, while the unprimed coefficients for the diagrams involving the internal $S$ baryon.

In Fig. 4, we show the quark-flavor flow picture for the baryon self-energy diagrams. Following the above rule and the rules defined in Sec. IV A, we obtain the contributions from the wavefunction renormalization for $T$ and $S$ baryons [20, 29],

$$W_T = \frac{i g_3^2}{f^2} \left[ \sum_\phi w_{\phi_{ab}}^T H(M_{a,b}, \Delta^{(B)} + \delta_{a,b}^{(B)}) - \sum_{\phi'} \tilde{w}_{\phi_{a,b}}^T \tilde{H}(M_{a,b}, \Delta^{(B)}) \right],$$

$$W_S = \frac{i g_3^2}{f^2} \left[ \sum_\phi w_{\phi_{ab}}^S H(M_{a,b}, \delta_{a,b}^{(B)}) - \sum_{\phi'} \tilde{w}_{\phi_{a,b}}^S \tilde{H}(M_{a,b}, 0) \right] + \frac{i g_3^2}{f^2} \left[ \sum_\phi w_{\phi_{ab}}^{S'} H(M_{a,b}, -\Delta^{(B)} + \delta_{a,b}^{(B)}) - \sum_{\phi'} \tilde{w}_{\phi_{a,b}}^{S'} \tilde{H}(M_{a,b}, -\Delta^{(B)}) \right],$$

(55)

where the summations are over the Goldstone mesons in SU(6$|3$) PQ$\chi$PT. The coefficients $w, w', \tilde{w}$, and $\tilde{w}'$ are presented in Table V in Appendix C while the mass parameters $\Delta^{(B)}$ and $\delta_{a,b}^{(B)}$ are defined above in Sec. II.

A single-$b$ baryon carries two light-flavor quarks, where one of them is contracted with the four-quark operators, while the other is the spectator quark. Therefore, the situation for the baryon tadpole and sunset diagrams is more involved compared to those for the meson diagrams. We first obtain the contributions from tadpole diagrams,

$$\mathcal{T}_{T(S)}^k = \frac{i}{f^2} \sum_\phi (x_{\phi_{ab}}^{T(S)} + \lambda^{sea} \overline{x}_{\phi_{ab}}^{T(S)} k) \mathcal{I}(M_{a,b}),$$

(56)
FIG. 4: Self-energy diagrams contributing to the matrix elements containing single-\(b\) baryons. The solid thick and thin lines denote the anti-\(b\) quark and the valence light quark, respectively, while the dashed thin line denotes the sea light quark. Diagram (c) and (b) are the hairpin structures. The diagrams including the internal \(S\) baryons lead to terms multiplied by \(w\) and \(\tilde{w}\), while those including the internal \(T\) baryons lead to terms multiplied by \(w'\) and \(\tilde{w}'\) in Eq. 55, where the tilded coefficients denote the hairpin structure. The diagrams obtained by interchanging the flavor indices \(a\) and \(b\), not shown in this figure, have also been taken into account in our results in Table V, where the coefficients \(x^T(S)\) and \(\tilde{x}^T(S)\) are given in Table VI in Appendix C. Like the case of \(B\) mesons, all hairpin diagrams cancel out and do not contribute to any one-loop tadpole corrections.

The quark-flavor flow structure for the baryon sunset diagrams can be summarized in Figs. 5 and 6. Notice that the four-quark operators do not change the spin of a single-\(b\) baryon as discussed in Sec. III and thus there are only three possible combinations of internal baryons, \(T_{ak} - T_{bk}, B_{ak} - B_{bk}\), and \(B^*_{ak} - B^*_{bk}\); the flavor indices \(a\) and \(b\) are contracted with \(\lambda_k^{PQ}\), while the index \(k\) is for the spectator quark. For the noneye-contraction, both nonhairpin and hairpin diagrams can give rise to the connected contribution to the matrix elements; the nonhairpin diagram in Fig. 5b is the only one giving rise to the disconnected contribution.
FIG. 5: Sunset diagrams contributing to the $\Delta B = 0$ matrix element of single-$b$ baryons without the hairpin structure. The solid thick and thin lines denote the anti-$b$ quark and the valence light quark, respectively, while the dashed thin line denotes the sea light quark. The crossed square is the four-quark operator $O^{PQ}_k$. Diagram (b) contributes to the $\bar{y}$ terms, while the diagrams including the internal $S$ and $T$ baryons lead to terms multiplied by $y$ and $y'$ in Eq. 58, respectively.

The diagrams obtained by interchanging the flavor indices $a$ and $b$, not shown in this figure, have also been taken into account in our results in Table VII, Table VIII and Table IX.

The contributions from the sunset diagrams for $T$ and $S$ baryons are summarized as

$$Q_k^{T} = \frac{i g_3^2}{f^2} \left[ \sum_\phi (y_{\phi a b}^{T,k} + \lambda^\text{sea} y_{\phi a b}^{T,k}) \mathcal{H}(M_{a,b}, \Delta^{(B)} + \delta^{(B)}_{a,b}) - \sum_{\phi'\phi} \tilde{y}_{\phi a \phi b}^{T,k} \tilde{\mathcal{H}}(M_{a,b}, \Delta^{(B)}) \right],$$

$$Q_k^{S_S} = \frac{i g_3^2}{3 f^2} \left[ \sum_\phi (y_{\phi a b}^{S,k} + \lambda^\text{sea} y_{\phi a b}^{S,k}) \mathcal{H}(M_{a,b}, \delta^{(B)}_{a,b}) - \sum_{\phi'\phi} \tilde{y}_{\phi a \phi b}^{S,k} \tilde{\mathcal{H}}(M_{a,b}, 0) \right],$$

$$Q_k^{S_T} = \frac{i g_3^2}{f^2} \left[ \sum_\phi (y_{\phi a b}^{S,k} + \lambda^\text{sea} y_{\phi a b}^{S,k}) \mathcal{H}(M_{a,b}, -\Delta^{(B)} + \delta^{(B)}_{a,b}) - \sum_{\phi'\phi} \tilde{y}_{\phi a \phi b}^{S,k} \tilde{\mathcal{H}}(M_{a,b}, -\Delta^{(B)}) \right],$$

where the summations are over the Goldstone mesons in SU(6|3) PQ\chi PT. The coefficients $y$, $y'$, $\bar{y}$, $\bar{y}'$, $\bar{y}$ and $\bar{y}'$ are presented in Table VII, Table VIII and Table IX in Appendix C.
FIG. 6: Sunset diagrams contributing to the $\Delta B = 0$ matrix element of single-$b$ baryons involving the hairpin structure. The solid thick and thin lines denote the anti-$b$ quark and the valence light quark, respectively, while the dashed thin line denotes the sea light quark. The crossed square is the four-quark operator $O^{\lambda Q}_{\lambda P Q}$. The diagrams including the internal $S$ and $T$ baryons lead to terms multiplied by $\tilde{y}$ and $\tilde{y}'$ in Eq. 58, respectively. The diagrams obtained by interchanging the flavor indices $a$ and $b$, not shown in this figure, have also been taken into account in our results in Table VII, Table VIII and Table IX.

C. Evaluation of one-loop contributions

In this subsection, we evaluate the one-loop diagrams including external $B_d$, $B_s$ mesons, and $\Lambda_b$ baryon to provide insight on chiral extrapolations of the matrix elements obtained from lattice simulations. As seen in Eqs. 50 and 51, the matrix elements of the singlet four-quark operators are complicated by the eye-contraction. For this reason, we restrict our attention to the matrix elements of the octet operators. We carry out the calculations in the QCD limit, where the masses of sea quarks are same with their counter part valence quarks. We fix $f = 0.132$ GeV, $\Delta^{(M)} = 45$ MeV, $\Delta^{(B)} = 200$ MeV, $M_{s,s} = 691$ MeV, $\tilde{\lambda}_1 = 0.189$ GeV$^{-1}$, and $\tilde{\lambda}_2 = 0.377$ GeV$^{-1}$. We also fix the renomalization scale by

\[\Delta^{(M)} \text{ and } \Delta^{(B)} \text{ are consistent with experiment. The value of } M_{s,s} \text{ is determined by the Gell-Mann-Okubo formulas using } (M_K)_{\text{phys}} = 0.498 \text{ GeV and } (M_\pi)_{\text{phys}} = 0.135 \text{ GeV, while the values of } \tilde{\lambda}_1 \text{ and } \tilde{\lambda}_2 \text{ are determined by Eq. 28 using } (M_{B_s})_{\text{phys}} - (M_{B_d})_{\text{phys}} = 0.087 \text{ GeV and } (M_{\Xi^0})_{\text{phys}} - (M_{\Lambda^0})_{\text{phys}} = 0.173.\]
\[ \mu = 4\pi f. \] The numerical values of the axial couplings \( g_1 \) and \( g_3 \) are taken from the recent lattice QCD calculations \([41, 42]\) as follows: \( 0.398 < g_1 < 0.5 \) and \( 0.58 < g_3 < 0.84 \) with central values of \( g_1 = 0.449 \) and \( g_3 = 0.71 \), respectively. We also vary the ratios of \( P^* \) to \( P \) and \( S \) to \( T \) LECs over the reasonable ranges, \( |\beta_2/\beta_1| < 2 \) for \( B \) mesons and \( |(-\beta_1^* + 2\beta_2^*)/\beta_3^*| < 2 \) for \( \Lambda_b \).

We first consider \( SU(3) \) theory in the isospin limit. The typical one-loop contributions involve kaons or \( \eta \)-mesons, where their chiral logarithms in the \( SU(2) \) chiral limit are given as \( (M_K^2/\mu^2) \log(M_K^2/\mu^2) \sim 0.21 \) or \( (M_\eta^2/\mu^2) \log(M_\eta^2/\mu^2) \sim 0.25 \). Using the pion mass over the typical range of \( 200 \text{ MeV} \leq M_\pi \leq 400 \text{ MeV} \) and the standard subtraction scheme in Eq. [A1] we find that the size of one-loop contributions is comparable with the LO matrix elements. Therefore, the convergence of the \( SU(3) \) chiral expansion of the matrix elements becomes questionable. Fortunately, for chiral extrapolations of lattice results one only requires knowledge of the pion mass dependence, and this can be achieved within \( SU(3) \) theory by taking the subtraction scheme below inspired by \( SU(2) \) chiral perturbation theory, where the one-loop chiral logarithms vanish in the \( SU(2) \) chiral limit \([20, 43, 44]\). Notice that the use of different subtraction schemes in one-loop integrals results in the finite renormalization of the LO matrix elements, but does not change physical quantities such as the hadron masses. We define the non-analytic functions \( I_{\text{sub}}(m) \) and \( H_{\text{sub}}(m, \Delta) \), which are relevant to the one-loop calculations, as

\[
I^{(\text{sub})}(m) = I(m) - I(m_0), \\
H^{(\text{sub})}(m, \Delta) = H(m, \Delta) - H(m_0, \Delta_0), \tag{58}
\]

where \( m_0 \) and \( \Delta_0 \) are the mass of Goldstone mesons and the mass difference between external and internal single-\( b \) hadrons at zero pion mass, respectively. We recall that the mass of a Goldstone meson is written as \( M_{a,b}^2 = B_0(m_a + m_b) \), i.e. \( M_K^2 = (M_{s,s}^2 + M_\pi^2)/2 \) and \( M_\eta^2 = (2M_{s,s}^2 + M_\pi^2)/3 \), and the strange quark mass \( M_{s,s} \) is fixed. The above non-analytic functions involve logarithms of the masses of Goldstone mesons, where for kaons and \( \eta \)-mesons these logarithms\(^{10}\) are much less sensitive to the pion mass than those for pions are. Note that

\(^{10}\) GeV, respectively. The physical values of hadron masses used in the determination of these various parameters are found in Ref. \([40]\).

In the \( SU(2) \) limit, where the mass of strange mesons can be treated on the same order as the chiral symmetry breaking scale, such logarithms vanish and we recover the subtraction scheme used in the context of \( SU(2) \) theory \([20]\).
FIG. 7: Infinite-volume one-loop contributions to the matrix elements of $\Delta B = 0$ four-quark operators containing an external $B_d$ for $\lambda_3^{PQ}$ (top-left) and $\lambda_8^{PQ}$ octets (top-right), and $B_s$ for $\lambda_8^{PQ}$ octet (bottom). For references, black dashed lines correspond to the LO contributions. Blue and red colors represent the connected and disconnected one-loop contributions, respectively; solid lines are obtained using $g_1 = 0.449$ and $\beta_2/\beta_1 = 1$, while inner and outer shaded regions are obtained by varying $g_1$ and both $g_1$ and $|\beta_2/\beta_1|$ over the range given in the text, respectively.

the subtracted terms are constants and appropriately absorbed by the counterterms.

Our current understanding on the matrix elements are very limited; see Ref. [12] for the summary of previous determinations. In particular, there are only a few quenched lattice simulations in Ref. [45, 46] for $B$ mesons and in Ref. [47] for $\Lambda_b$. Instead of using the definite values of the LECs $\beta_1$ and $\beta_3'$, therefore, we rather calculate the NLO one-loop contributions normalized by the LO LECs as follows:

$$\langle B|O^{\lambda_k^{PQ}}|B\rangle_{1\text{-loop}} = \frac{1}{\beta} \langle B|O^{\lambda_k^{PQ}}|B\rangle - C_B^k,$$

where $B$ denotes the external single-$b$ hadron, while $\beta$ denotes the LECs $\beta_1$ and $\beta_3'$ for $B$ mesons and $\Lambda_b$ baryon, respectively. Here we use the subtraction scheme defined in Eq. 58 and neglect the analytic terms in Eq. 50 and Eq. 51. The results of one-loop calculations are
FIG. 8: Infinite-volume one-loop contributions to the matrix elements of $\Delta B = 0$ four-quark operators containing an external $\Lambda_b$ baryon for $\lambda_8^{\text{PQ}}$ octet. For references, black dashed lines correspond to the LO contributions. Blue and red colors represent the connected and disconnected one-loop contributions, respectively; solid lines are obtained using $g_3 = 0.71$ and $(-\beta'_1 + 2\beta'_2)/\beta'_3 = 1$, while inner and outer shaded regions are obtained by varying $g_3$ and both $g_3$ and $|(-\beta'_1 + 2\beta'_2)/\beta'_3|$ over the range given in the text, respectively.

summarized in Fig. 7 for external $B_d$ and $B_s$, and in Fig. 8 for $\Lambda_b$. In each figure, the black dashed line is the LO contribution, while the blue and red solid curves are the connected and disconnected one-loop contributions, respectively; we use the central values of $g_1$ and $g_3$ with the ratios of LECs being unity, $\beta_2/\beta_1 = (-\beta'_1 + 2\beta'_2)/\beta'_3 = 1$. The variations of the axial couplings and of both the axial couplings and the ratios of LECs are represented by the inner dark-shaded and outer light-shaded regions, respectively. It is clear from these figures that the sunset diagrams provide an important part of the disconnected one-loop contributions to the matrix elements, and thus invoke a relatively large uncertainties due to the unknown LECs for $B^*$ mesons and $S$-type baryons. In addition, the matrix elements containing external $B_s$ have relatively small pion-mass dependence compared to those containing $B_d$ because of the absence of pion loops, where their logarithmic behavior are almost fades away.

For idealized values of LECs, namely $\beta_2 = \beta_1$ and $\beta'_3 = -\beta'_1 + 2\beta'_2$, the disconnected diagrams provide a sizable contribution to the matrix elements for the $\lambda_8^{\text{PQ}}$ octet because of large SU(3) breaking effects in the light-quark sector. In the case of the $\lambda_3^{\text{PQ}}$ octet, the matrix elements containing $B_s$ and $\Lambda_b$ do not exist to all orders in the chiral expansion provided isospin symmetry is exact. As seen in Fig. 7, on the other hand, the matrix element containing $B_d$ receives connected one-loop contributions which are exactly opposite
to those for the $\lambda_{8}^{PQ}$ octet, but it receives no disconnected contributions. Since the eye-contractions also vanish, one can in principle determine this matrix element very accurately from the calculation of connected diagrams which are accessible by current lattice techniques. Moreover, its precise value will play a crucial role in the investigation of the life-time ratio $\tau(B^{+})/\tau(B_d)$ [12].

Now, we explore the finite volume effects in $\Delta B = 0$ matrix elements for external $B_d$, $B_s$ mesons, and $\Lambda_b$ baryon. To this end, we consider the change in the finite volume matrix elements relative to the infinite ones normalized by their three-level values,

$$
\langle B \mid O_{\lambda_{8}^{PQ}}^{k} \mid B \rangle_{FV} = \frac{\langle B \mid O_{\lambda_{8}^{PQ}}^{k} \mid B \rangle(L) - \langle B \mid O_{\lambda_{8}^{PQ}}^{k} \mid B \rangle(\infty)}{\langle B \mid O_{\lambda_{8}^{PQ}}^{k} \mid B \rangle_{\text{tree}}} \tag{60}
$$

where $B$ denotes the external single-$b$ hadron. With a lattice volume fixed by $L = 2.5$ fm we present the results for $B_d$, $B_s$ in Fig. 9 and for $\Lambda_b$ in Fig. 10, where the blue and red solid curves are the connected and disconnected one-loop contributions; we use the central values of $g_1$ and $g_3$ with the ratios of LECs being unity, $\beta_2/\beta_1 = (\beta'_1 + 2\beta'_2)/\beta'_3 = 1$. The variations of the axial couplings and of both the axial coupling and the ratios of LECs are represented by the inner dark-shaded and outer light-shaded regions, respectively. In the case of $B_d$ finite volume effects in the connected diagrams for $\lambda_3^{PQ}$ are exactly same with those for the $\lambda_{8}^{PQ}$ octet, while the effects in the disconnected diagrams vanish. In the cases of $B_s$ and $\Lambda_b$, the change in Eq. 60 for $\lambda_3^{PQ}$ is ill-defined because the corresponding tree-level matrix elements do not exist. Finite volume effects for $B_s$ are considerably suppressed because pion loops do not contribute to these matrix elements in the QCD limit, while the sizes of finite volume effects for $\Lambda_b$ are similar to those for $B_d$. As seen in these figures, the dominant uncertainty in our calculations, especially of the disconnected contributions, arises from the variation of the ratio of unknown LECs.

V. CONCLUSION

We have determined the matrix elements of $\Delta B = 0$ four-quark operators involving single-$b$ hadron external states relevant for the calculation of $V_{ub}$ and lifetimes of single-$b$ hadrons at the next-to-leading order in heavy hadron chiral perturbation theory. We performed these calculations in SU(6|3) partially quenched theories including finite volume effects in the isospin limit, where connected and disconnected contributions are analyzed in a
natural manner. At the tree level, the disconnected contributions called the eye-contractions vanish for the octet operators due to the light-flavor symmetry, but they do not for the singlet operator. At the next-to-leading order in chiral expansion for the exemplified cases of external $B_d$, $B_s$, and $\Lambda_b$, we find that for the $\lambda_{8}^{PQ}$ octet the disconnected contributions are suppressed but still sizable due to the large light-flavor symmetry breaking. In the case of the $\lambda_{3}^{PQ}$ octet with an external $B_d$ meson, on the other hand, we find that the matrix elements receive contributions solely from connected diagrams. This result suggests that the precise calculation of these particular matrix elements, which have phenomenological impact on the determination of the lifetime ratio $\tau(B^+)/\tau(B_d)$, is possible using current lattice techniques.

Additionally, our results are necessary to extrapolate the QCD and PQCD lattice data of these matrix elements from the unphysical light-quark masses used in the finite volume lattice simulations to their physical values. We find that such chiral extrapolations are complicated by more than two unrelated low-energy constants appearing in the leading-
FIG. 10: Finite volume effects in the matrix elements of $\Delta B = 0$ four-quark operators containing an external $\Lambda_b$ baryon for $\lambda^8_{PQ}$ octet in a $L = 2.5$ fm lattice. The details are same with those in Fig. 8.

Finite volume effects are at the few-percent level for a lattice volume of $L = 2.5$ fm, and should be taken account into the extrapolations as they become important in high-precision calculations.

Acknowledgments

The author would like to acknowledge William Detmold and C.-J. David Lin for their contributions to the early stage of this work, and for helpful discussions. The author also thanks Brian C. Tiburzi for many fruitful discussions and comments. This work is supported by the U.S. National Science Foundation, under Grant No. PHY12-05778.

Appendix A: Integrals and sums

The ultra-violet divergences in various loop integrals are regularized by dimensional regularization and have the term

\[ \tilde{\lambda} = \frac{2}{4-d} - \gamma_E + \log(4\pi) + 1, \]  

(A1)

where \( d \) is the number of space-time dimension. This is a commonly used scheme in \( \chi \)PT calculations [48], which is different from the \( \overline{\text{MS}} \) scheme by the constant “1” on the right-hand side of the above equation. The requisite subtracted integrals appearing in the one-loop calculations in the framework of PQ\( \chi \)PT can all be obtained from the following integrals,

\[ I(m) \equiv \mu^{4-d} \int \frac{d^d k}{(2\pi)^d} \frac{1}{k^2 - m^2 + i\epsilon} - \frac{im^2}{16\pi^2} \tilde{\lambda} \]

\[ = -\frac{im^2}{16\pi^2} \log \left( \frac{m^2}{\mu^2} \right), \]  

(A2)
where $\mu$ is the renormalization scale and with

$$R(x) \equiv \sqrt{x^2 - 1} \log \left( \frac{x - \sqrt{x^2 - 1} + i \epsilon}{x + \sqrt{x^2 - 1} + i \epsilon} \right).$$  \hspace{1cm} (A4)$$

To study finite volume effects in the limit $mL \gg 1$, we consider a cubic spatial box of $V = L^3$ with periodic boundary conditions. The three-momenta are quantized as $\vec{k} = (2\pi/L)\vec{e}$, where $e_1, e_2, e_3 = -L/2 + 1, \cdots, L/2$. After subtracting the ultra-violet divergence like as in Eq. [A2] and Eq. [A3] we instead obtain the sums

$$I(m) \equiv \frac{1}{L^3} \sum_{\vec{k}} \int \frac{dk_0}{2\pi} \frac{1}{k^2 - m^2 + i\epsilon}$$

$$F(m, \Delta) \equiv \frac{(g^{\rho\nu} - \nu^{\rho\nu})}{(d-1)} \frac{1}{L^3} \sum_{\vec{k}} \int \frac{dk_0}{2\pi} \frac{k_{\rho} k_{\nu}}{k^2 - m^2 + i\epsilon}(v \cdot k - \Delta + i\epsilon)$$

$$= F(m, \Delta) + F_{FV}(m, \Delta).$$  \hspace{1cm} (A6)$$

The finite-volume pieces are given by [18–20]

$$I_{FV}(m) = - \frac{i}{4\pi^2} m \sum_{\vec{n} \neq 0} \frac{1}{nL} K_1(nmL)$$

$$\xrightarrow{mL \gg 1} - \frac{i}{4\pi^2} \sum_{\vec{n} \neq 0} \sqrt{\frac{m\pi}{2nL}} \left( \frac{1}{nL} \right) e^{-nmL} \times \left\{ 1 + \frac{3}{8nmL} - \frac{15}{128(nmL)^2} + O \left( \left[ \frac{1}{nmL} \right]^3 \right) \right\},$$

$$F_{FV}(m, \Delta) = \frac{i}{12\pi^2} \sum_{\vec{n} \neq 0} \frac{1}{nL} \int_0^{\infty} d|\vec{k}| \frac{|\vec{k}| \sin(n|\vec{k}|L)}{\sqrt{|\vec{k}|^2 + m^2 + \Delta}} \left( \Delta + \frac{m^2}{\sqrt{|\vec{k}|^2 + m^2}} \right),$$

$$\xrightarrow{mL \gg 1} \frac{i}{24\pi} \sum_{\vec{n} \neq 0} \frac{e^{-nmL}}{nL} A$$  \hspace{1cm} (A7)$$

where $\vec{n} = (n_1, n_2, n_3)$ with $n_i \in \mathbb{Z}$, $n \equiv |\vec{n}|$, and

$$A = e^{(z^2)[1 - \text{Erf}(z)]} + \left( \frac{1}{nmL} \right) \left[ \frac{1}{\sqrt{\pi}} \left( \frac{9z^3}{4} - 2z^2 \right) + \left( \frac{3}{2} - 2z^2 \right) e^{(z^2)[1 - \text{Erf}(z)]} \right]$$

$$+ \left( \frac{1}{nmL} \right)^2 \left[ \frac{1}{\sqrt{\pi}} \left( \frac{39z^3}{64} - \frac{11z^5}{32} + \frac{9z^5}{16} - \frac{z^7}{8} \right) - \left( \frac{3}{2} - \frac{8}{8} \right) e^{(z^2)[1 - \text{Erf}(z)]} \right] + O \left( \left[ \frac{1}{nmL} \right]^3 \right),$$

$$31$$
with
\[ z \equiv \left( \frac{\Delta}{m} \right) \sqrt{\frac{n m L}{2}}. \]

The functions appearing in the one-loop results are
\[ \mathcal{H}(m, \Delta) \equiv \frac{\partial F(m, \Delta)}{\partial \Delta}, \quad (A8) \]
and
\[ \mathcal{H}(M_{a,b}, \Delta) = \delta_{a,b} \{ A_{a,b} \mathcal{H}(M_{a,b}, \Delta) + (1 - A_{a,b}) \mathcal{H}(M_X, \Delta) + C_{a,b} \mathcal{H}_{\eta'}(M_{a,b}, \Delta) \} 
\]
\[ + (1 - \delta_{a,b}) \{ D_{a,b}^{(a)} \mathcal{H}(M_{a,a}, \Delta) + D_{a,b}^{(b)} \mathcal{H}(M_{b,b}, \Delta) + D_{a,b}^{(x)} \mathcal{H}(M_X, \Delta) \}, \quad (A9) \]
where the function \( \mathcal{H}_{\eta'} \) from the integral of hairpin diagrams is
\[ \mathcal{H}_{\eta'}(m, \Delta) \equiv \frac{\partial \mathcal{H}(m, \Delta)}{\partial m^2}. \quad (A10) \]

The coefficients in the function \( \mathcal{H} \) are defined by
\[ A_{u,u} = \frac{2 (\delta_{V}^2 - M_{\pi}^2 + M_X^2) \delta_{S}^2}{(M_{\pi}^2 - M_X^2)^2} + \frac{3}{2}, \quad A_{s,s} = \frac{3 \left( 8 \delta_{S}^2 + (2 \delta_{V}^2 - M_{\pi}^2 + M_{s,s}^2)^2 \right)}{(2 \delta_{V}^2 + 4 \delta_{V}^2 s_s - M_{\pi}^2 + M_{s,s}^2)^2}, \]
\[ C_{u,u} = 3 \delta_{S}^2 - \frac{2 \delta_{V}^2}{M_{\pi}^2 - M_X^2}, \quad C_{s,s} = \frac{6 \delta_{S}^2 \left( 2 \delta_{V}^2 - M_{\pi}^2 + M_{s,s}^2 \right)}{2 \delta_{V}^2 + 4 \delta_{V}^2 s_s - M_{\pi}^2 + M_{s,s}^2}, \]
\[ D_{u,s}^{(u)} = \frac{2 \delta_{V}^2 \left( M_{\pi}^2 - M_{s,s}^2 + 2 \delta_{S}^2 \right)}{(M_{\pi}^2 - M_{s,s}^2)(M_{\pi}^2 - M_X^2)}, \quad D_{u,s}^{(s)} \]
\[ = \frac{2 \delta_{S}^2 \left( M_{\pi}^2 - M_{s,s}^2 - 2 \delta_{V}^2 \right)}{(M_{\pi}^2 - M_{s,s}^2)(M_{s,s}^2 - M_X^2)}, \quad D_{u,s}^{(x)} = \frac{M_{\pi}^2 - M_X^2 - 2 \delta_{V}^2}{(M_{\pi}^2 - M_X^2)(M_{s,s}^2 - M_X^2)}, \quad (A11) \]
where \( M_{a,b} = B_0(m_a + m_b), \delta_{V}^2 = \delta_{V}^2 \) \( u,u - u,u, \delta_{S}^2 = \delta_{S}^2 = M_{s,s}^2 - M_{s,s}^2, \) \( M_{\pi} = M_{u,u}, \) \( M_X = M_{u,u} + 2 M_{s,s}^2 - 2 \delta_{V}^2 - 4 \delta_{V}^2 s_s). \) Notice that we take the isospin limit as in Eq. 20.

In the QCD limit (setting valence and sea quark masses to be identical), we have
\[ A_{u,u}^{QCD} = \frac{3}{2}, \quad A_{s,s}^{QCD} = 3, \quad C_{u,u}^{QCD} = 0, \quad C_{s,s}^{QCD} = 0, \]
\[ D_{u,s}^{(u)}^{QCD} = 0, \quad D_{u,s}^{(s)}^{QCD} = 0, \quad D_{u,s}^{(x)}^{QCD} = 1. \quad (A12) \]

**Appendix B: coefficients for chiral one-loop contributions in B-meson**

In this appendix, we present the coefficients in Eq. 53 and Eq. 54 corresponding to the tadpole- and sunset-type diagrams. These coefficients are summarized in Table III and Table IV.
TABLE III: Coefficients $x_{\phi}^{B,k}$ and $\bar{x}_{\phi}^{B,k}$ in Eq. 53 in the isospin limit. In the case of $B_d$, the coefficients for $k = 0, 8$ and for $k = 3$ are identical and opposite to those of $B_u$, respectively. The coefficients for $B_s$ with $k = 3$ are all zeros.

| $k$  | $B_u$ | $B_s$ |
|------|-------|-------|
| 0    | $-2$  | 0     |
|      | $-1$  | 0     |
|      | 0     | $-1$  |
| 3    | $-2$  | 0     |
|      | $-1$  | 0     |
| 8    | $-2$  | 0     |
|      | $-1$  | 0     |

TABLE IV: Coefficients $\bar{y}_{\phi}^{B,k}$ and $\tilde{y}_{\phi}^{B,k}$ in Eq. 54 in the isospin limit. In the case of $B_d$, the coefficients for $k = 0, 8$ and for $k = 3$ are identical and opposite to those of $B_u$, respectively. The coefficients for $B_s$ with $k = 3$ are all zeros.

| $k$  | $B_u$ | $B_s$ |
|------|-------|-------|
| 0    | 6     | 0     |
|      | 3     | 6     |
|      | 0     | 0     |
| 3    | 6     | 0     |
|      | $-6$  | 0     |
| 8    | 6     | 0     |
|      | $-6$  | 0     |

Appendix C: Coefficients for chiral one-loop contributions in $B$-baryon

In this appendix, we present the coefficients in Eq. 55, Eq. 56, and Eq. 58 corresponding to the self-energy, tadpole, and sunset one-loop diagrams. These coefficients are summarized in Table V, Table VI, Table VII, Table VIII, and Table IX.
TABLE V: Coefficients $w_{\phi_{ab}}^T$, $w_{\phi_{ab}}^S$, $w_{\phi_{aa} \phi_{bb}}^T$, and $\tilde{w}_{\phi_{aa} \phi_{bb}}^S$ in Eq. 55 in the isospin limit. $\Sigma$, $\Xi$, and $\Xi'$ baryons with different 3-components of the isospin have the same coefficients because of the isospin symmetry. $\phi_{us}$ and $\phi_{su}$ are distinguished by the appearance of their mass parameters $\delta_{us}^{(B)}$ and $-\delta_{us}^{(B)}$ in the propagator of internal baryons.

|      | $w_\phi$ | $w_{\phi\phi'}$ |
|------|----------|-----------------|
|      | $uu$ $us$ $su$ $ss$ $uj$ $ur$ $sj$ $sr$ | $\eta_u\eta_s$ $\eta_u\eta_s$ $\eta_s\eta_s$ |
| $\Lambda_b$ | 3 0 0 0 0 6 3 0 0 | 0 0 0 |
| $\Xi_b$ | 0 $\frac{3}{2}$ $\frac{3}{2}$ 0 3 $\frac{3}{2}$ 3 $\frac{3}{2}$ | $\frac{1}{2}$ $-1$ $\frac{1}{2}$ |
| $\Sigma$ | 1 0 0 0 2 1 0 0 | $\frac{2}{3}$ 0 0 |
| $\Xi'$ | 0 $\frac{1}{2}$ $\frac{1}{2}$ 0 1 $\frac{1}{2}$ 1 $\frac{1}{2}$ | $\frac{1}{6}$ $\frac{1}{3}$ $\frac{1}{6}$ |
| $\Omega$ | 0 0 0 1 0 0 2 1 | 0 0 $\frac{2}{3}$ |

|      | $w'_\phi$ | $w'_{\phi\phi'}$ |

| $\Sigma$ | -1 0 0 0 0 2 1 0 0 | 0 0 0 |
| $\Xi'$ | 0 $-\frac{1}{2}$ $-\frac{1}{2}$ 0 1 $\frac{1}{2}$ 1 $\frac{1}{2}$ | $\frac{1}{6}$ $-\frac{1}{3}$ $\frac{1}{6}$ |
| $\Omega$ | 0 0 0 $-1$ 0 0 2 1 | 0 0 0 |
TABLE VI: Coefficients $x_{\phi}^{T(S),k}$ and $\bar{x}_{\phi}^{T(S),k}$ in Eq. 56 in the isospin limit. For $k = 0, 8$, we find $x_{\phi}^{\Lambda_b} = x_{\phi}^{\Sigma_b}$, $x_{\phi}^{\Lambda_b} = x_{\phi}^{\Xi_b}$, $x_{\phi}^{\Xi_b} = x_{\phi}^{\Xi_b}$, and $x_{\phi}^{\Xi_b} = x_{\phi}^{\Xi_b}$, where $\Sigma$, $\Xi$, and $\Xi'$ baryons with different 3-components of the isospin have the same coefficients because of isospin symmetry. For $k = 3$, we find $x_{\phi}^{\Sigma^-} = -x_{\phi}^{\Sigma^+}$ and $x_{\phi}^{\Xi^-} = x_{\phi}^{\Xi^+} = -x_{\phi}^{\Xi^+} = -x_{\phi}^{\Xi^+}$, while $x_{\phi}^{\Lambda_b} = x_{\phi}^{\Sigma_b} = x_{\phi}^{\Omega_b} = 0$ for possible Goldstone mesons. Coefficients $\bar{x}$ are all zeros for $k = 3$.

| $x_{\phi}^{T(S),k}$ | $\bar{x}_{\phi}^{T(S),k}$ |
|---------------------|---------------------|
| $u j$ | $u r$ | $s j$ | $s r$ | $u j$ | $u r$ | $s j$ | $s r$ |
| $k = 0$ | $\Lambda_b$ | $-2$ | $-1$ | 0 | 0 | 2 | 1 | 0 | 0 |
| | $\Xi$ | $-1$ | $-\frac{1}{2}$ | $-1$ | $-\frac{1}{2}$ | $1$ | $\frac{1}{2}$ | $1$ | $\frac{1}{2}$ |
| | $\Omega$ | 0 | 0 | $-2$ | $-1$ | 0 | 0 | 2 | 1 |
| $k = 3$ | $\Xi^+ \frac{1}{2}$ | $-1$ | $-\frac{1}{2}$ | 0 | 0 | 0 | 0 | 0 | 0 |
| | $\Sigma^+$ | $-2$ | $-1$ | 0 | 0 | 0 | 0 | 0 | 0 |
| $k = 8$ | $\Lambda_b$ | $-2$ | $-1$ | 0 | 0 | 2 | $-2$ | 0 | 0 |
