Associate Professor, Department of Chemistry, University of Nairobi, Kenya

Abstract:  
This work investigates the degradation rate of 4-chlorophenol using photocatalysts. Chlorophenols and their compounds are a nuisance as they are recalcitrant to degradation in the environment. Three morphologically different Titanium dioxide catalysts, A, B and C, were immobilized on microscopic glass at a layer of 0.5 mg/cm² and annealed between 500-700°C. The three different TiO₂ powders were characterized using Scanning Electron Microscopy, X-Ray Diffraction and Brunauer Emmett Teller to determine their specific surface area, crystalline and particle sizes. A four–position photocatalytic reactor illuminated by two Ultra violet lamps of wavelength range 320-400 nm and intensity I=27.87 mW/m² was used to degrade the 4-Chlorophenol in 2 hrs. Aliquots of the degraded 4-chlorophenol were drawn every 30 minutes and analyzed using UV-Vis spectroscopy at λ=226 nm. The optimum annealing temperature of all TiO₂ was found to be 650°C, with type B of hexagonal morphological structure and particle size of 28±2nm having the highest 4-chlorophenol degradation rate, of 71.21%.

Keywords: Photocatalytic degradation, 4-chlorophenol, TiO₂, annealing temperature, morphology

1. Introduction

Chlorinated phenols are categorized as first-degree pollutants due to their persistent toxicity, suspected carcinogeticity and mutagenicity. Chlorophenols (CPs) in general, when released into the environment poses serious ecological problems to all living organisms (Movahedyan et al., 2008). Among the chlorophenols, 4-chlorophenol has attracted a lot of interest owing to its direct relevance to the environment and its unique photochemical characteristic (Krysa et al., 2006).

Chlorophenols find their way into water systems as a result of discharge from chemical industries, have proved resistant to conventional chemical and biological treatments. Some of the industries from which large volumes of chlorophenols are discharged include; petroleum refining, production of pesticides, paint, plastic, resins, textiles, iron-ore processing, solvent synthesis and pharmaceutical productions (Gomez et al., 2009; Movahedyan et al., 2009; Olaniran and Igbinosa, 2011; Pera-Titus et al., 2004; Pi et al., 2007). As a result of water pollution, the sustainable approach to water sources management should therefore include treatment technologies that reduce the negative effects and promote sustainable use of water resources by facilitating recycling and reusing of wastewater (Catrinescu et al., 2011).

Advanced Oxidation Processes (AOPs) is one such process that constitute a collection of established treatment technologies which depend on the formation of hydroxyl radicals (-OH) that mineralize non-selectively all contaminants into carbon dioxide and water (Assadi & Eslami, 2010; Gaya et al., 2009; Dan et al., 2004). Researchers have investigated on the removal phenolic compounds using several techniques that include; Ultra-violet/H₂O₂, Ultra-violet/catalyst, photo-Fenton process, MW/NiO, Ultra-violet/H₂O₂/TiO₂, O₃/ZnO, Graphite and graphene oxides, Microwave/Ultra-violet and UV/O₃/TiO₂ (Marianna, 2006; Lin et al., 2008; Ghaly et al., 2001; Kuo and Lin, 2009; Lai et al., 2007; Chiou et al., 2007; Dixit et al., 2010; Tabatabaie et al., 2011; Bustos-Ramirez et al., 2015; Seo et al., 2017; Gimeno et al., 2005). In addition, the use of microbial cultures Alcaligenes in a fermenter has been reported by (Westmeier and Rehm, 1987) to remove 4-Chlorophenol in wastewater. These methods have largely not been very effective and there is need for further research for the effective and economical removal of 4-Chlorophenol from wastewater. This work investigates the role of annealition temperature in the UV/TiO₂ treatment system to degrade 4-Chlorophenol in wastewater. This work anticipates that the optimization of Titanium dioxide’s mechanical and chemical properties as well as illumination with ultraviolet light improves the catalytic activity, hence the degradation rate of 4-Chlorophenol. At annealing temperatures of 500-700°C, TiO₂ morphology transforms from anatase to rutile phase, thereby improving its photocatalytic activity. Anatase TiO₂ is mostly used for environmental management, such as water purification, wastewater treatment and water disinfections (Carp et al., 2004; Eslami et al., 2007). It is biologically and chemically inert, stable with respect to photo and chemical corrosion, low cost, active over a wide range of pH, high refractive index, efficient and long-term stability (Ghosh et al., 2009). A draw-back in the application of TiO₂ is its high band gap energy of 3.2 e. V, that allows titanium dioxide to absorb
only UV light of wavelength lower than 388 nm thereby reducing solar light harvesting efficiency down to 5% (Ajmal et al., 2014; Gaya et al., 2009; Barnes et al., 2010). Anatas also has a low mineralization level that is acquired when on large-scale applications and therefore requires a final polishing stage (Gimeno et al., 2004). These shortcomings have renewed efforts to research on reliable and more effective catalysts (Catrinescu et al., 2011; Li et al., 2009). Photocatalytic oxidation processes are related to catalytically active metal oxides such as ZnO, TiO$_2$, and ZrO$_2$ which are semiconductors and remove contaminants in wastewater (Lo et al., 2004). They are mainly the oxides of transition metals (Lai et al., 2008; Stoyanova and Christoskova, 2011; Stoyanova et al., 2003). The equations below indicate the reactions that take place when TiO$_2$ reacts as a semi-conductor.

$$\text{TiO}_2 + hv \rightarrow e_{\text{CB}}^- + h_{\text{VB}}^+ \quad (1)$$

$$\text{O}_2 + e_{\text{CB}}^- \rightarrow \text{O}_2^- \quad (2)$$

$$\text{H}_2\text{O} + h_{\text{VB}}^+ \rightarrow \text{OH}^- + \text{H}^+ \quad (3)$$

The contaminant in this study, 4-Chlorophenol contains pesticide properties. It is a characteristic faint yellow liquid with an unpleasant, penetrating odour, molecular mass $M_r$ = 128.56 g.mol$^{-1}$ with a chemical formula $C_6H_5OCl$. The structural formula of 4-Chlorophenol is shown in figure 1 below.

![Figure 1: 4-Chlorophenol](image)

2. Materials and Methods

2.1. Chemicals

Three different types of Titanium dioxide powder were sourced from Sigma-Aldrich and identified as A, B & C. Lanthanum hexaboride and 4-Chlorophenol of purity 99% was also obtained from Sigma - Aldrich.

2.2. Equipment

UV/Vis spectrophotometer model 4000 from Shimadzu Ltd, UV light intensity meter, X-ray diffractometer and Scanning Electron Microscope model Tescan VEGA3 equipment were used

2.3. Methods

Morphological Characterization of TiO$_2$ powder catalysts using Scanning Electron Microscopy, X-Ray diffraction and Brunauer Emmett-Teller procedures are explained here below.

2.3.1. Scanning Electron Microscopy (SEM) – Crystal size

A Tescan VEGA3 Scanning Electron Microscope equipped with a field emission source was preferred over regular SEM with Lanthanum hexaboride filament as a high voltage source for morphological characterization. This is because of its high resolution and brightness at low accelerating voltages that allows for clearer images. Prior to SEM, the samples were first mounted on an aluminum stub using a double-sided carbon tape, and then coated with a thin layer of 10-30 nm composed of 60:40 gold-palladium alloy by means of vacuum sputtering coating using a Denton Desk 1 Sputter-Coater under a 70 mtorr vacuum. Other conditions included: (SEM HV 20.0 kV, view field 6.36 μm and SEM mag 30.0 kx).

- Two sample of each TiO$_2$ powder were inscribed for identification
- The samples were dried at an oven 60°C for 3 hours
- The samples were loaded into the SEM and blown with inert nitrogen gas to protect any further oxidation reactions.
- The acceleration voltage was set at 20 KV, lowest magnification (30X) and TV mode.
- The coarse focus was switched on and the focus knob adjusted to a safe working distance of 14 mm.
- The focus was switched to slow scan mode and magnification increased. The samples stage was brought up slowly by pressing z-axis UP key. The variable button was opened up to open a small variable window on the screen. The image was focused within the small screen using outer focus ring and inner focus ring until indicator light reaches the middle.
- The image was previewed and adjusted to contrast and the image set-up window closed. The image acquire icon was clicked to record the image formed and the image saved.
2.3.1.1. X-Ray Diffractometer (XRD) – Crystallite Size

Particle sizes are calculated by XRD using the Scherer’s equation $l = kl /\beta \cos \theta$. $k$ is a constant taken to be 0, 9 (assuming no crystal distortions in the lattice), $\beta$ is the width at half maximum of the radians corrected for the instrumental broadening and $\theta$ is the diffraction angle in degrees.

- Scan parameters: start and end 2q limits 0 -130 - 2q
- Step size 0.5 -0.1 - 2q
- Step time (1 sec)
- Start scan
- When scan was completed the file was saved

2.3.1.2. Brunauer Emmett Teller (BET) – Surface Area Analysis

The BET surface area was measured through a multipoint method utilizing adsorption data in the relative pressure (P/Po) in the range 0.005-0.3 using nitrogen (99.99%) physico-sorption at 200°C.

- The system used liquid nitrogen in a 500 ml Dewar flask placed on the stage of the instrument.
- ZnO and TiO$_2$ were heated at 150°C for 2 hours to remove adsorbed water
- The resolution of the images formed were set at 80 seconds

2.3.2. Measurement of Irradiation Intensity

The irradiation intensity emitted by UV lamps in the four-hole photoreactor was measured using a light intensity meter positioned at a distance of 0 cm next to the metallic openings from which UV light was irradiated. The light intensity values were measured at the start and end of each experiment and included in the final value of the rate of photocatalytic degradation. The UV light intensity was measured at $I=27.87$ mW/m$^2$.

UV-Vis spectrophotometric measurements of 4-chlorophenol A stock solution of 0.0001 mol.L$^{-1}$ in a 500 ml round bottomed flask was made and its absorbance measured using a UV-Vis spectrophotometer. An aliquot of 5 ml 4-Chlorophenol was put into the cuvette and placed in the spectrophotometer. A full UV-Vis scan of 4-Chlorophenol sample was carried out at wavelengths between 200- 600 nm and the spectrum recorded as shown in figure 6.

2.3.3. Calibration Curve – 4-Chlorophenol Spectral Analysis Molar Extinction Coefficient (E)

The coefficient (E) is calculated from the Beer Lambert's law shown in (4) below;

$$A = \varepsilon L c$$  \hspace{1cm} (4)

Where:

- $A$ is the amount of light absorbed by samples at specific wavelengths ($\lambda$)
- $E$ is the molar extinction coefficient
- $L$ is the length of cuvette used to measure absorbance
- $C$ is the concentration of the absorbing sample

To determine the extinction coefficient of 4-chlorophenol ($E$), at 226 nm concentrations of solutions were prepared: $1 \times 10^{-5}$ mol.L$^{-1}$, $2.5 \times 10^{-5}$ mol.L$^{-1}$, $5 \times 10^{-5}$ mol.L$^{-1}$ and $1 \times 10^{-4}$ mol.L$^{-1}$. A calibration curve for 4-Chlorophenol using different solution concentrations was obtained and is shown in figure 7 and its molar extinction coefficient calculated.

2.4. Photocatalytic Degradation of 4-Chlorophenol

The experimental temperature was set at 23°C. The four cuvettes were filled with 25 ml of $1 \times 10^{-4}$ mol.L$^{-1}$ of 4-chlorophenol and placed against each of the four holes in the photocatalytic reactor before the UV lamps and the magnetic stirrer were switched on. At the start of the experiment, absorbance was measured and the value recorded for each of the TiO$_2$ catalyst layers. The fourth cuvette was the experimental control. The absorbance of the solutions was determined at $\lambda= 226$ nm and after every 30 minutes of photocatalytic treatment, 5 ml of the 4-Chlorophenol solution was withdrawn from each cuvette, its absorbance recorded till the 120th minute. The rate of 4-Chlorophenol degradation was considered to cover a geometrical area 0.000875 m$^2$ covered by TiO$_2$ catalyst immobilized on microscopic glass. The rate was calculated as shown by formula (5) and (6) below and expressed as (mol.m$^{-2}$.W$^{-1}$).

$$r_A = \frac{(c_0 - c_{60})V}{t_{60} - t_0} \cdot \frac{1}{A}$$  \hspace{1cm} (5)

- $r_A$ rate of 4-Chlorophenol in degradation (mol.m$^{-2}$h$^{-1}$)
- $c_0$ initial 4-Chlorophenol in concentration (mol.L$^{-1}$)
- $c_{60}$ 4-Chlorophenol concentration after 1 hour (mol.L$^{-1}$)
- $t$ time at which irradiation started (0 hours.)
- $t_{60}$ time of irradiation (1 hour)
- $V$ volume of 4-Chlorophenol irradiated in cuvette (0.025 ml)
- $A$ irradiated geometric surface area of particulate film (0.000875 m$^2$)

The rate of photodegradation relative to incident UV light intensity is then calculated according to equation 6 below.
\[ r_I = \frac{r_A}{I} \]  

Where \( r_I \) is the rate of 4-Chlorophenol photocatalytic degradation (mol h\(^{-1}\) W\(^{-1}\)) and \( I \) is UV light intensity (mW/m\(^2\)).

2.4.1. Preparation of TiO\(_2\) Coated Layers Immobilized on Microscopic Glass

Catalyst suspensions of concentration 10 g.L\(^{-1}\) were prepared from the 3 samples; A, B and C in 100 ml volumetric flasks. The suspensions were further homogenized in an ultrasonic bath for 30 seconds to break-up any agglomerates present. A volume of 3.75 ml of the TiO\(_2\) suspensions were taken using a 5 ml syringe and immobilized onto a clean, dry and degreased microscopic glass slides of dimensions 75 mm x 25 mm and placed on ceramic tile and allowed to dry at room temperature for 1 hour. The coated layers were then dried at 50\(^\circ\)C in an oven for 30 minutes to further fixate the catalyst particles onto the glass. The final procedure involved the annealing of the layers attached onto porcelain crucibles in a furnace at 500, 550, 600, 650 & 650\(^\circ\)C for a duration of 2 hours. The annealed layers were trimmed to reduce the geometric area covered by the catalyst to 0.000875 m\(^2\) and loading of 0.5 mg/cm\(^2\). The procedure described above was used to prepare particulate layers for all the three catalysts.

2.4.2. Photocatalytic Degradation Reactor

The photocatalytic reactor was operated in batch mode and consisted of a magnetic stirrer. Three cuvettes of 30 ml were placed onto the holes illuminating UV light. The stirring rate was set at 900 rotations/min. Each of the cuvettes was filled with 25 ml of 4-Chlorophenol c(1x10\(^{-4}\) mol.L\(^{-1}\)). The photoreactor was attached to a thermostat to regulate its temperature as shown in figure 2 below. The TiO\(_2\) coated layers prepared from the procedure described in section (2.4.1) were suspended using metallic clips and dipped into cuvettes containing 4-Chlorophenol solutions. The cuvettes consisting of 4-Chlorophenol solutions and TiO\(_2\) coated layers were illuminated with UV light from 2 lamps. The intensity of the UV light was measured by a light intensity meter.

3. Results and Discussion

3.1. Characterization of TiO\(_2\) Powder Catalysts

| Sample | Agglomerate Size (Nm) (SEM) | Crystal Size (Nm) (XRD) | Specific Surface Area (M\(^2\)/G) (BET) |
|--------|-----------------------------|-------------------------|----------------------------------------|
| A      | 200-300                     | 28                      | 50                                     |
| B      | 300                         | 169                     | 10                                     |
| C      | 100-300                     | 9                       | 250                                    |

*Table 1: Morphological Characterization - (XRD, SEM & BET)*

Table 1 and figure 3, 4 and 5 presents the results from the morphological characterization of the catalysts used in this study.
The crystalline sizes obtained from XRD measurements and SEM estimations, show that from figure 3, 4 and 5, we observe catalyst individual crystals and agglomerates. The particle sizes of catalyst B (169 nm) were bigger compared to the other catalysts, but had the smallest specific surface area (10 m²/g). Smaller particle sizes were observed in catalyst C (9 nm) and the largest specific surface area (250 m²/g). Catalyst A had particles size of (28 nm) and specific surface area (50 m²/g). The morphological characterization indicates distinct properties between the three powder catalysts.

3.2. UV-Vis Spectra of 4-Chlorophenol

Figure 6 below shows a UV-Vis spectrum for 4-Chlorophenol c (1×10⁻⁴ mol.L⁻¹) to determine λ_(max)
The scan showed a maximum absorption wavelength peaks at $\lambda = (226 \text{ nm and } 282 \text{ nm})$ which means 4-Chlorophenol absorbs light in the UV region. The photocatalytic degradation experiments in this work was determined at $\lambda = 226 \text{ nm}$, which was more pronounced compared to $\lambda = 282.5 \text{ nm}$. It implies that 4-Chlorophenol has peak absorbance at 226 and 282 nm. This figure is quite close to $\lambda = 227 \text{ nm}$ and 280 nm reported in literature by (Bustos-Ramírez et al., 2015). Between $\lambda = (300-600 \text{ nm})$. The contaminant in the study 4-Chlorophenol, was noted not to absorb any visible light ($\lambda = 390-790 \text{ nm}$) as observed in figure 6.

3.3. Calibration curve 4-Chlorophenol (Molar Extinction Coefficient ($\epsilon$))

The Molar Extinction Coefficient was determined through a standard calibration curve plotted in Figure 7 below.

![Figure 7: Calibration Curve 4-Chlorophenol](image)

To determine the extinction coefficient ($\epsilon$) of 4-Chlorophenol, the following concentrations 4 solutions of various concentrations were prepared from a stock solution of $1 \times 10^{-4} \text{ mol. L}^{-1}$. These were, ($1 \times 10^{-5} \text{ mol.L}^{-1}, 2.5 \times 10^{-5} \text{ mol.L}^{-1}, 5 \times 10^{-6} \text{ mol.L}^{-1}$ and $1 \times 10^{-4} \text{ mol.L}^{-1}$). A cuvette of 1 cm unit length and a UV-Vis spectrophotometer, absorbance for these solutions was measured at $\lambda_{\text{max}} = 226 \text{ nm}$. By plotting absorbance against concentration, a calibration curves were generated and using the line equation, the molar extinction coefficient ($\epsilon$) was determined to be $799.65 \text{ mol}^{-1}\text{dm}^{3}\text{cm}^{-1}$.

3.4. Photocatalytic Degradation of 4-Chlorophenol

The removal of 4-Chlorophenol was measured by its rate of its photocatalytic degradation. This work studied the effect of catalyst annealing temperature, morphology and its subsequent effect on the rate of degradation. The rates of 4-Chlorophenol was studied using catalysts annealed at temperatures between 500-700°C and recorded in figure 8, 9, 10, 11 & 12. The influence of TiO$_2$ annealing temperatures on the rates of 4-Chlorophenol degradation are discussed in figure 13 and 14.

![Figure 8: Degradation of 4-Chlorophenol Using Selected TiO$_2$ Catalysts Annealed At 500°C](image)

3.4.1. Degradation of 4-Chlorophenol Using Selected TiO$_2$ Commercial Catalysts Annealed at 500°C

The results above indicated that at 500°C, optimum rates of 4-Chlorophenol degradation rates was achieved. The B catalyst was the most photo catalytically active and C the least. At this. After 2 hours of UV-TiO$_2$ photocatalytic degradation system, the removal of 4-Chlorophenol was measured; B-$68.02\%$, C-$46.25\%$ and A-$56.46\%$. This result was influenced by the irregular shape of TiO$_2$ particles at low temperatures causing low kinetic energy that is not sufficient to induce coalescence of the individual TiO$_2$ grains.
3.4.2. Degradation of 4-Chlorophenol Using Selected TiO$_2$ Catalysts Annealed at 550°C.

![Figure 9: Degradation of 4-Chlorophenol Using Selected TiO$_2$ Catalysts Calcined at 550°C.](image)

Figure 9 showing photocatalyst of B decreasing 4-Chlorophenol the fastest with irradiation time compared to A and C. On the other side Photocatalyst C shows the slowest decrease of the concentrations of 4-Chlorophenol. Changes in 4-Chlorophenol concentration after 2 hours are then used to calculate degradation rates as follows; B - 64.85%, C - 39.68% and A - 61.11%. Compared to 500°C, the degradation rates were observed to decrease by a collective average 5.08%. The probable cause is the sintering of the immobilized catalysts. The possible explanation can be in the loss of TiO$_2$ particles from deposited layers. This means that photodegradation takes place not only on the surface of immobilised TiO$_2$ particles but also on small amount of suspended particles. This is the only probable explanation and will have to be verified in further work.

3.4.3. Degradation of 4-Chlorophenol Using Selected TiO$_2$ Catalysts Annealed at 600°C.

![Figure 10: Degradation of 4-Chlorophenol Using Selected TiO$_2$ Catalysts Calcined at 600°C.](image)

Figure 10 shows that B catalysts degraded 4-Chlorophenol more rapidly compared to A and C. After 2 hours of UV/TiO$_2$ photocatalytic treatment, the removal of 4-Chlorophenol was determined to be; (B - 67.64%, C - 44.78% and A - 61.68%). Compared to immobilized layers annealed at 550°C, the rate of 4-Chlorophenol degradation increased slightly at 600°C. A possible explanation could be the modification in catalyst morphology as a result of annealing.

3.4.4. Degradation of 4-Chlorophenol Using Selected TiO$_2$ Catalysts Annealed at 650°C.

![Figure 11: Degradation of 4-Chlorophenol Using Selected TiO$_2$ Catalysts Annealed at 650°C.](image)
Figure 11 indicate the optimum annealing temperature for the degradation of 4-Chlorophenol was determined to be 650°C. At this calcination temperature, the rates of degradation for 4-Chlorophenol was optimized. Compared to the results shown in figure 8, 9 and 10, B catalyst was most photocatalytically active and C the least. After 2 hours of photocatalytic degradation, the removal of 4-Chlorophenol was measured to be; (B-71.21%, C-43.80% and A-63.61%). At this annealing temperature the TiO₂ crystallite structure is suggested to be modified by annealing temperature and subsequently the rate of 4-Chlorophenol removal.

3.4.5. Degradation of 4-Chlorophenol Using Selected TiO₂ Catalysts Annealed at 700°C

From figure 12 as observed from the other annealing temperatures, B catalyst was the most photocatalytically active and C the least. After 2 hours of photocatalytic degradation, the removal of 4-Chlorophenol was measured at; (B-67.19%, C-35.36% and A-61.36%). At 700°C most likely the crystal grains in the immobilized films would get larger as a result of densification. The rates of 4-Chlorophenol removal declined by 12.98% at temperature interval 650-700°C. This means that annealing temperatures above 650°C have a negative effect on rate of 4-Chlorophenol degradation due to the morphological TiO₂ transformation from anatase to rutile. The rutile phase is less crystalline compared to anatase phase leading to decreased rates of 4-Chlorophenol.

3.4.6. Photocatalytic Degradation of 4-Chlorophenol C(1×10⁻⁴ M) Using TiO₂ Catalysts Annealed at Temperatures between 500-700°C

Figure 13 below analyses the correlation between the rates of 4-Chlorophenol degradation, the type of TiO₂ catalyst and annealing temperatures 500-700°C.

An increase in calcination temperatures in the range 500-550°C had an average negative effect. 5.08% on the degradation rate of 4-Chlorophenol which can be explained by sintering of catalyst particles that causes it to bind and fuse together causing the particles to grow and form agglomerates. A significant increase 12.98% in 4-Chlorophenol degradation was observed at calcination temperatures between 550-650°C. Between 650-700°C the degradation rates of 4-Chlorophenol decreased by 14.71% due to morphological Phase transformation from anatase to rutile phase at 700°C annealing temperature. The results show that 650°C is optimum calcination temperature to achieve effective degradation of 4-Chlorophenol, the findings show that the following levels of efficiency in removing 4-Chlorophenol was achieved at 650°C; (A-63.61%, C-43.80% and B-71.21%). The findings in figure 13, corroborate the results obtained in figure 8, 9, 10, 11 & 12 that indicate similar trends. The shifting rates of 4-Chlorophenol removal with increased annealing temperatures can be explained as follows; the most influential parameter would be the decrease in the density of structural defects, whereas the decrease in surface area would have a less influence in the removal of 4-Chlorophenol. This is caused by the
poor adsorption properties of 4-Chlorophenol and density of defects with regards to catalyst surface area for most aromatic contaminants such as 4-Chlorophenol. This means photocatalytic reactions react in the vicinity of TiO$_2$ and not on its surface. The higher specific surface area of C does not positively affect the rates of 4-Chlorophenol degradation because it does not presumably react principally at the surface.

3.4.7. Effect of TiO$_2$ Calcination Temperature on the Concentration of 4-Chlorophenol

Figure 14 shows change in 4-Chlorophenol concentration with increasing calcination temperature between 500-700°C.

![Figure 14: Changes in 4-Chlorophenol Concentration with Selected TiO$_2$ Catalyst after 1 Hr. of Photocatalytic Degradation](image)

The results in figure 14 are similar to the findings obtained in figure 13. Figure 14 shows the correlation between fluctuations in 4-Chlorophenol c (mol.L$^{-1}$), TiO$_2$ catalyst and annealing temperature. Furthermore, the findings corroborate the results shown in figure 8, 9,10,11,12 & 13.

Annealing of TiO$_2$ catalysts remove defects on the crystalline planes, thereby reducing TiO$_2$ internal stresses and improving ductility of metallic alloys as observed between annealing temperatures 550-650°C. The reduction in the rates of 4-Chlorophenol above 650°C was caused by morphological transformations from anatase to rutile phase, thus decreasing TiO$_2$ crystallinity and photocatalytic activity.

4. Conclusions

The present study established a high photocatalytic activity of TiO$_2$ for the degradation of 4-Chlorophenol under UV light irradiation. B catalyst showed the highest photocatalytic activity for degradation of 4-Chlorophenol and C the least photoactivity. Annealing had a significant influence on the resultant photocatalytic activity of the produced immobilized layers. Annealing temperatures above 650°C negatively affect rates of 4-Chlorophenol degradation. However, higher annealing temperatures of TiO$_2$ weights more for the removal of the 4-Chlorophenols from wastewater. Significantly, the optimum annealing temperature was determined to be 650°C. The results show that increases TiO$_2$ crystal size favoured higher rates of 4-Chlorophenol removal, while catalyst surface area had little effect, however powder catalyst surface area has little effect on 4-Chlorophenol degradation. In the present study, no correlation between specific surface area and rate of 4-chlorophenol removal was established. The surface morphology of TiO$_2$ immobilized layers was influenced by annealing temperature.
