Abstract. This paper designs a unidirectional high gain, low-cost cascading ring antenna with coaxial feeding and metal without the dielectric. The designed antenna suits for high power transfer applications such as radar communications, wireless local area network (WLAN), and base stations. The use of gap-coupled cascading rings in the design enhances the gain to 13.4 dBi at the resonance frequency of 2.45 GHz, improving the side lobes level and front-to-back ratios. The proposed antenna has symmetrical half power beam width (HPBW) in H-plane and E-plane of 37 degree and 36.5 degree, respectively. The cross-polarization field component of the antenna below –25 dB in H-plane, and below –45 dB in E-plane is obtained from the measurements. The measured antenna has 10 dB bandwidth of 95 MHz i.e., 2.405–2.50 GHz that covers the ISM 2.45 GHz band. The measured and HFFS simulated results are found in good agreement.

Keywords
Cascaded square ring, high gain, metallic structure, symmetrical radiation pattern, wireless local area network (WLAN)

1. Introduction

In modern wireless communication systems, we require unidirectional high gain antennas for long-distance communication systems such as base stations, radar communications, and coal-mine applications. The antenna for such applications requires a unidirectional radiation pattern, high gain, low-cross-polarization, symmetrical radiation pattern, low front-to-back ratio, and high-power handling capacity. The non-planar antenna can easily achieve wide bandwidth, but the planar structure is preferred because of its simple structure and easy fabrication process. Many high gain microstrip antennas have been studied in this literature survey. However, the conventional rectangular microstrip antenna has low gain and low power handling capacity because of the dielectric substrates [1], [2]. An antenna array technique is used to improve the gain of the microstrip antenna, but it requires the design of the feeding network that increases the antenna’s cost, and the feeding network absorbs power too [3], [4]. Recently, some meta-material techniques have been used to enhance the gain of the microstrip antenna by reducing the dielectric constant through the air holes, but this approach makes design complex and has low power handling capacity compared to metallic antennas [5], [6]. The Yagi-Uda antenna array enhances the gain, but it requires directors, reflectors, and feed elements, which increases the design complexity and cost [7], [8]. The dielectric resonator antenna (DRA) gives wide bandwidth but low gain and low power handling capacity [9], [10]. Therefore, antenna array configurations are required to enhance the dielectric resonator antenna’s gain, but it requires an external feeding network that increases antenna complexity and design cost [11], [12]. Thus, feeding network and dielectric materials should be avoided to reduce the cost and complexity of the antenna; hence, metallic antennas with a simple structure are preferred [13], [14]. The metallic antenna array reported in [15] has 10% impedance bandwidth and peak gain of 11.81 dBi, but it occupies a large volume (3.5λ × 0.43λ × 0.26λ), and it requires an external feeding network. The waveguide-fed antenna reported in [16] has 14% bandwidth and a high gain of 15 dBi, whereas it requires a bulky design that occupies a large volume, too. The dual-band metallic antenna reported in [17], [18] has a bandwidth of 10%, but peak gain is smaller than 11 dBi.

The works, as mentioned above, require an external feeding network with low gain and low power handling capacity due to the use of dielectric substrates. In this paper, a high gain antenna is designed by cascading two-gap-coupled rings to the central ring antenna, and simple coaxial feeding is used for excitation. The four parallel arms of the cascading rings have in-phase current components; hence, these arms are the primary radiators. The outer arms have a small current compared to the middle arms. Thus, the directivity of the antenna is enhanced due to the reduction of the side lobes. The cascaded rings improve the HPBW in H-plane and make the radiation pattern symmetrical. The measurement antenna has a resonance frequency...
of 2.45 GHz with 10 dB bandwidth from 2.405–2.500 GHz. The proposed antenna has a high gain of 13.4 dBi at 2.450 GHz with HPBW of 37 degree in H-plane and 36.5 degree in E-plane.

2. Structure of the Primary Ring Antenna

The primary square ring antenna structure is shown in Fig. 1, and its dimensions are indicated by the symbols. The square ring of inner side length $a$, width $w$, and thickness 0.5 mm is suspended at height $h$ on the circular ground plane of radius $R$. The side of the square ring, which is perpendicular to the $y$-axis, is fed from a 50-$\Omega$ coaxial probe and its opposite side is shorted to the ground plane through a shorting pin of radius 1 mm. The structure of the primary ring antenna is simulated by taking dimensions ($R = 110$ mm, $a = 46.5$ mm, $w = 2.5$ mm, and $h = 12$ mm). The simulated return loss and directivity are plotted in Fig. 2 and Fig. 3, respectively. As the height $h$ increases, the bandwidth is increased, while resonance frequency is shifted to the lower side, and the antenna’s directivity is slightly reduced. The simulated resonance frequency of 2.54 GHz with 10 dB bandwidth of 2.46–2.62 GHz is observed with the directivity of 11 dBi at resonance.

Fig. 1. The design structure of a primary ring antenna.

Fig. 2. The simulated return loss of the antenna with variation in height $h$.

3. Working Principle

The current density of the proposed antennas is simulated at 2.54 GHz, and is shown in Fig. 4. The current flows from the coaxial probe to the ground plane through two non-fed arms and a shorting pin. The current path is indicated in Fig. 4, which shows that the total length traversed by the current is equal to the wavelength. Therefore, by equating the whole current path with wavelength yields the mathematical expression for the calculation of the resonance frequency of the primary ring antenna. The resonance frequency 2.54 GHz is obtained from HFSS simulation and 2.56 GHz is obtained from the analytical equation (1). Thus, the simulated and calculated resonance frequencies are approximately matched.

$$2a+2h \approx \lambda \quad \text{or} \quad f \approx \frac{c}{2(a+h)} \quad (1)$$

where $a$ is the side length of square ring, $c$ is the speed of light in free space, $h$ is the suspended height of the ring from the ground plane, $f$ is resonance frequency and $\lambda$ is free-space wavelength corresponding to the resonance frequency.

The normalized radiation pattern of the primary ring antenna simulated at resonance frequency 2.54 GHz, is shown in Fig. 5. The simulated antenna has broadside radi-
Fig. 5. Simulated radiation pattern at 2.54 GHz (a) H-plane, (b) E-plane.

ation with low cross-polarization below –22 dB in the H-plane and below –48 dB in E-plane. The simulated radiation pattern has asymmetrical half-power beam width (HPBW) of 50 degree in H-plane and 31 degree in E-plane. The side lobe level is below –9 dB in E-plane, and there is no side lobe in H-plane. The antenna is unidirectional with front to back ratio of 12 dB at resonance frequency 2.54 GHz.

The far-field radiation mechanism of the proposed antenna is similar to a horizontally polarized λ/2 dipole antenna placed at height h above the ground plane, as shown in Fig. 6 [19]. In our design, two parallel non-feeding arms of the square ring radiate similar to the λ/2 dipole antenna with spacing a between the two radiating sides. Therefore, the radiation pattern is similar to the two elements dipole array placed at height h over the ground plane. We can derive the equation for maximum radiation intensity, radiated power, and directivity of a horizontal dipole antenna placed at height h over the ground plane using equations (2)–(5) from [19].

\[
U_{\text{max}} = \frac{\eta}{2} \left( \frac{\lambda}{\lambda} \right)^2 \sin^2 (kh) \cos^2 \left( \frac{ka}{2} \cos \Phi \right) \quad \text{for} \quad h \leq \lambda / 4 , \quad (6)
\]
\[
U_{\text{max}} = \frac{\eta}{2} \left( \frac{\lambda}{\lambda} \right)^2 \frac{1}{2} \quad \text{for} \quad \left\{ h = \frac{\lambda}{8}, a = \frac{\lambda}{2} \right\} \quad \text{and} \quad \Phi = \frac{\pi}{2}, \quad (7)
\]
\[
U_{\text{max}} = \frac{\eta}{2} \left( \frac{\lambda}{\lambda} \right)^2 \quad \text{for} \quad \left\{ h = \frac{\lambda}{4}, a = \frac{\lambda}{2} \right\} \quad \text{and} \quad \Phi = \frac{\pi}{2}, \quad (8)
\]
\[
P_{\text{rad}} = 0 \quad \text{for} \quad \left\{ h = \frac{\lambda}{4}, a = \frac{\lambda}{2} \right\} \quad \text{and} \quad \Phi = \frac{\pi}{2}. \quad (9)
\]

Here, k is propagation constant, h is the height of the dipole antenna from the ground plane, l is the length of the dipole antenna and η is the wave impedance in free space (120πΩ).

If height h is equal to zero, then the dipole antenna is shorted with the ground plane, and it does not radiate, and similar things happen with the proposed antenna. The proposed antenna’s radiation intensity is derived by multiplying the square of the array factor with the radiation intensity of the horizontal dipole antenna. The derived radiation intensity of the square loop antenna is given in (6).

\[
D = \frac{4\pi U_{\text{max}}}{P_{\text{rad}}} = \left\{ \frac{4 \sin^2 (kh)}{R(kh)} \right\} \quad \text{for} \quad h \leq \frac{\lambda}{4} .
\]

\[
R(kh) = \left[ \frac{2}{3} \sin^2 (kh) - \frac{\cos (2kh)}{(2kh)^2} + \frac{\sin (2kh)}{(2kh)^2} \right].
\]

4. Gain Enhancement by Cascading Rings

The primary square ring antenna design discussed in the preceding section has a directivity of ~11 dBi at reso-
nance frequency 2.54 GHz. In this section, the directivity of the primary square ring antenna is improved with two in-phase cascaded rings. The structure of the proposed cascaded antenna is shown in Fig. 7.

When the primary ring antenna is simulated, it has only two sides with a common mode current; hence, these sides radiate like a horizontal dipole antenna placed at height $h$ over the ground plane, and its collective effect enhances the directivity. However, the cascaded ring antenna has two extra gap-coupled rings.

Therefore, the cascaded ring antenna has four parallel sides, which has an in-phase current, and these parallel sides radiate like four elements horizontal dipole array over the ground plane and enhance the directivity. The return loss of the cascading ring antenna is simulated with a variation of the gap $G$, the result is shown in Fig. 8. When there is no gap between the arms, i.e., $G = 0$ mm, then the current flows from the coaxial probe to the shorting pin through the inner loop and outer loop and impedance is matched at the frequency of the outer loop. Hence the resonance frequency is determined by equating the circumference of the outer loop with wavelength, which is at 1.8 GHz, as obtained from HFSS simulation.

If a gap $G$ is created in the outer arms of the cascaded ring antenna then the current's significant components flow from the coaxial probe to the shorting pin through the sides of the middle ring. Hence resonance frequency is due to the central primary ring, which is identical to the resonance frequency of the primary ring antenna derived in (1), but a slight shift in resonance frequency is occurred due to the change of reactive part of the impedance of the cascaded antenna. For example, the $G = 4$ mm antenna has a resonance frequency of 2.45 GHz, closer to 2.54 GHz, the resonance frequency of the primary ring antenna. As the gap $G$ increases, less current flows in the outer side, and the majority of the current flows in the inner loop; hence the resonance frequency is shifted toward the resonance frequency of the primary ring antenna. The antenna simulated for $G = 6$ mm has a resonance frequency of 2.48 GHz. The surface current density of the proposed cascaded antenna is simulated at 2.45 GHz, which is shown in Fig. 9.

The current flows in all the parallel sides are in phase; hence these sides are the main radiating elements. The current flow in the antenna structure is drawn in Fig. 10. The broadside directivity of the antenna is simulated with

**Fig. 10.** Principle of the proposed cascaded antenna structure.

**Fig. 11.** Simulated directivity with variation in gap $G$. 
variation in $G$, as shown in Fig. 11, when $G = 0$ mm, then the directivity is 11.9 dBi at the resonance frequency of 1.8 GHz. While gap $G$ increases, the resonance frequency is shifted at the higher side, and the antenna's directivity reaches 13.7 dBi at 2.45 GHz for the gap $G = 3$ mm. There is a 1.80 dB improvement in directivity which is due to a reduction in side lobe level.

The simulated antenna with the single ring has asymmetrical HPBW with 52 degree in H-plane and 31 degree in E-plane. The HPBW improved and became symmetrical by introducing the cascading rings. The cascaded antenna with 35 degree HPBW in H-plane, and 36 degree HPBW in E-plane is obtained from the HFSS simulation, as shown in Fig. 12. The cascading ring improved the front-to-back ratio 17 dB, and side lobe level below 13 dB, in E-plane and the side lobe below 22 dB in H-plane as obtained from the simulation. In Fig. 13, the antenna's 3-D radiation pattern is simulated at 2.45 GHz, and the antenna has a directivity of 13.7 dBi, and the side lobe is reduced in the direction of cascading rings (H-plane).

5. Fabrication and Measurements

The cascading ring antenna prototype is shown in Fig. 14. It has been fabricated from a copper sheet of a thickness of 0.5 mm. A simple 50-ohm SMA connector feeds the middle ring, and its opposite side is shorted to the ground plane through a pin of radius 1 mm. The soldering of the coaxial probe and shorting pin provides the support to suspend at height $h$ of the cascading ring over the circular ground plane. The antenna is fabricated with dimensions of radiating rings: $a = 44$ mm, $w = 2.5$ mm, $G = 4$ mm, $h = 12$ mm, and $R = 110$ mm. The designed antenna has advantages of being planar in structure, fabricated with metal only, small area occupied by radiating elements, simple feeding, and high power handling capacity due to metallic structure.

The return loss of the proposed antenna is simulated and measured using a vector network analyzer, and measurement and simulated results are mentioned in Fig. 15. The results show that the simulated antenna has a 10-dB impedance bandwidth from 2.410–2.495 GHz with a resonance frequency of 2.45 GHz. However, the measured antenna has a 10-dB impedance bandwidth from 2.405 GHz to 2.50 GHz with a resonance frequency of 2.45 GHz.

The gain of the proposed antenna is measured from a two-port vector network analyzer in an anechoic chamber. The reference antenna (double ridged waveguide horn antenna) is first connected to port 2, and the proposed cascaded ring antenna is connected to port 1. We activate $S_{21}$ for the frequency range (2.3–2.6 GHz). After this, we normalized the calibration, which gives 0 dB $S_{21}$ over the selected sweep. This means the gain is now normalized to the
reference antenna. Now we replace the reference antenna at port 1 and the proposed cascaded antenna at port 2, and we measured $S_{21}$, which is the gain of the proposed cascaded antenna concerning the reference antenna. Hence the gain of the proposed antenna can be determined by (10).

$$G_{\text{cascaded}} = S_{21} + G_{\text{ref}} \quad (10)$$

Here $G_{\text{cascaded}}$ is the gain of the proposed cascaded antenna and $G_{\text{ref}}$ is the gain of the reference antenna. The gain of the reference antenna $G_{\text{ref}}$ is 9.8 dBi at 2.45 GHz, and $S_{21}$ is 3.6 dB obtained from the measurements; hence the gain of the measured antenna is 13.4 dBi from (10). The measured broadside gain is matched with the HFSS simulated gain of 13.6 dBi as shown in Fig. 16.

The normalized radiation pattern of the antenna is simulated and measured in H-plane at 2.45 GHz, as shown in Fig. 17(a). The simulated antenna has a low cross-polarization level below –30 dB, in H-plane and the cross-polarization level below –40 dB, is obtained in E-plane, as shown in Fig. 17(b).

| Ref. | Total planar area & Total height | Resonance frequency & 10-dB bandwidth | Peak gain | Dielectric constant | Feeding technique |
|------|---------------------------------|--------------------------------------|-----------|--------------------|------------------|
| [16] | $4 \lambda^2$ & 0.93$\lambda$ | 5.8 GHz & 14% (5.40–6.20 GHz) | 15 dBi    | 1                  | Wave-guide feeding |

| This work | $2.53 \lambda^2$ & 0.12$\lambda$ | 2.45 GHz, 3.87% (2.405–2.50 GHz) | 13.4 dBi  | 1                  | Coaxial probe     |

**Tab 1.** Comparisons of the proposed high gain antenna and previously reported high gain antennas.
The measured antenna has a cross-polarization level below −25 dB, HPBW, and 36.5 degree in H-plane. The cross-polarization level below −40 dB and HPBW 37 degree are measured in E-plane, and the antenna is unidirectional with a front-to-back ratio of 15 dB. The measured results are in good agreement with simulated results. There is a slight deviation in simulated and measured results due to fabrication and measurement errors.

A performance comparison of various reported antennas in the literature along with the proposed antennas is tabulated in Tab. 1. The proposed design shows good enactment over existed ones.

6. Effect of Ground Plane Size

In this section, the performance of the proposed antenna is studied concerning changes in the radius of the ground plane. In Fig. 18, we have simulated the broadside directivity of the proposed antenna regarding the ground plane radius $R$. The simulated broadside directivity of the antenna is shown in Fig. 18. The directivity is increased as the ground plane radius increases from $R = 100$ mm to $R = 120$ mm due to the enhancement of the effective area. However, the broadside directivity of the antenna decreases as the ground plane size increases from $R = 120$ mm to $R = 140$ mm due to destructive interference from the large open-ended ground plane.

7. Conclusion

This paper proposed a high gain antenna for radar communication, WLAN applications, base stations, and energy harvesting applications. The antenna structure is simple and designed from copper, and less complex coaxial feeding is used for the excitation. In the proposed antenna, in-phase cascading rings are used for gain enhancements. The designed antenna has a high gain of 13.4 dBi with a symmetrical radiation pattern in the E and H planes at the resonance frequency. The operating principle of the proposed antenna is explained using four elements horizontal dipole antenna array placed over the ground plane.
