The Pfaffian Calabi–Yau, its Mirror, and their link to the Grassmannian G(2,7)

Einar Andreas Rødland

January 20, 1998

Abstract

The rank 4 locus of a general skew-symmetric $7 \times 7$ matrix gives the pfaffian variety in $\mathbb{P}^{20}$ which is not defined as a complete intersection. Intersecting this with a general $\mathbb{P}^6$ gives a Calabi–Yau manifold. An orbifold construction seems to give the 1-parameter mirror-family of this. However, corresponding to two points in the 1-parameter family of complex structures, both with maximally unipotent monodromy, are two different mirror-maps: one corresponding to the general pfaffian section, the other to a general intersection of $G(2,7) \subset \mathbb{P}^{20}$ with a $\mathbb{P}^1$. Apparently, the pfaffian and $G(2,7)$ sections constitute different parts of the A-model (Kähler structure related) moduli space, and, thus, represent different parts of the same conformal field theory moduli space.

1 The Pfaffian Variety

Let $E$ be a rank 7 vector space. For $N \in E \wedge E$ non-zero, we look at the locus of $\wedge^3 N = 0 \in \wedge^6 E$: the rank 4 locus of $N$ if viewed as a skew-symmetric matrix. This defines a degree 14 variety of codimension 3 in $\mathbb{P}(E \wedge E) \cong \mathbb{P}^{20}$. As $N$ is skew-symmetric, this variety is defined by the pfaffians, i.e. square roots of the determinants, of the $6 \times 6$ diagonal minors of the matrix. Intersecting this with a general 6-plane in $\mathbb{P}(E \wedge E) \cong \mathbb{P}^{20}$ will give a 3-dimensional Calabi–Yau. In coordinates $x_i$ on $\mathbb{P}^6$, the matrix $N$ can be written $N_A = \sum_{i=0}^6 x_i A_i$ where the $A_i \in E \wedge E$ are skew-symmetric matrices spanning the $\mathbb{P}^6$. Denote this variety $X_A \subset \mathbb{P}^6$. The pfaffian variety in $\mathbb{P}^{20}$ is smooth away from the rank 2 locus which has dimension 10. Hence, by Bertini’s theorem, the variety $X_A$ is smooth for general $A$.

Definition 1 Let $N_A = \sum_{i=0}^6 x_i A_i$ where $A_i$ are $7 \times 7$ skew-symmetric matrices. Let $X_A \subset \mathbb{P}^6$ denote the zero-locus of the pfaffians of the $6 \times 6$ diagonal minors of $N_A$: ie., the rank 4 locus of the matrix.
For $P = N^3 \in \bigwedge^6 E$, $\mathcal{O} = \mathcal{O}_{P(E)}$, there are exact sequences

$$0 \rightarrow (\bigwedge^7 E^\vee)^2 \otimes \mathcal{O}(-7) \rightarrow \bigwedge^7 E^\vee \otimes E^\vee \otimes \mathcal{O}(-4)$$

and

$$0 \rightarrow (\bigwedge^7 E^\vee)^2 \otimes \bigwedge^2 E^\vee \otimes \mathcal{O}(-8) \rightarrow \bigwedge^7 E^\vee \otimes \mathcal{O}(-7)$$

or more simply, for $P = [p_i]$ the pfaffians with proper choice of sign and ordering,

$$0 \rightarrow \mathcal{O}_{P^6}(-7) \rightarrow 7\mathcal{O}_{P^6}(-4) \rightarrow 7\mathcal{O}_{P^6}(-3) \rightarrow \mathcal{O}_{P^6} \rightarrow \mathcal{O}_X \rightarrow 0$$

and

$$0 \rightarrow 21\mathcal{O}_{P^6}(-8) \rightarrow 48\mathcal{O}_{P^6}(-7) \rightarrow 28\mathcal{O}_{P^6}(-6) \rightarrow J^2_X \rightarrow 0. \quad (4)$$

These sequences together with $0 \rightarrow J^2_X \rightarrow J_X \rightarrow N_X^\vee \rightarrow 0$, $0 \rightarrow N_X^\vee \rightarrow \Omega_{P^6}|_X \rightarrow \Omega_X \rightarrow 0$, and $0 \rightarrow \Omega_{P^6}|_X \rightarrow 7\Omega_X(-1) \rightarrow \mathcal{O}_X \rightarrow 0$ give the cohomology of the general, smooth manifold:

**Proposition 2** The general variety $X_A \subset P^6$ is smooth with $h^{1,0} = h^{2,0} = 0$, $h^{3,0} = 1$, $h^{1,1} = h^{2,2} = 1$, $h^{1,2} = h^{2,1} = 50$, $\chi = -98$, and $\omega_X \cong \text{Ext}^3(\mathcal{O}_{X_A}, \omega_{P^6}) \cong \mathcal{O}_{X_A}$; hence, it is a Calabi–Yau manifold. When $X_A$ is singular, we have trivial dualizing sheaf, $\omega^\vee_{X_A} \cong \mathcal{O}_{X_A}$.

## 2 The Canonical Bundle

In order to find the Picard–Fuchs operator, a global section of the canonical bundle is needed. In the case of a complete intersection, one could simply have used the dual of $\bigwedge_j dp_j$ or its residue form $\text{Res} \bigwedge_i dx_i / \prod_j p_j$. The pfaffian variety, however, is not a complete intersection. For $p_i$ the pfaffian of $N$ with row and column $i$ removed, the polynomials $p_{\mu_0}, p_{\mu_1}, p_{\mu_2}$, $\mu_i$ a permutation of $Z_7$, give a complete intersection wherever the submatrix $N_{\mu_3\mu_4\mu_5\mu_6}$ of $N$ containing rows and columns $\mu_3$, $\mu_4$, $\mu_5$, and $\mu_6$ has rank 4: i.e., its pfaffian $\text{Pf}(N_{[\mu_3\mu_4\mu_5\mu_6]})$ is different from zero. This follows from $N \cdot P = 0$. Hence,

$$(-1)^\mu dp_{\mu_0} \wedge dp_{\mu_1} \wedge dp_{\mu_2} / \text{Pf}(N_{[\mu_3\mu_4\mu_5\mu_6]}) \quad (5)$$

gives a global section of $\mathcal{O}_{P^6}(7) \otimes \mathcal{O}_{P^6} \wedge^3 N_X^\vee \cong \omega_X^\vee$. As $\omega_X^\vee \cong \mathcal{O}_X$, this section must be non-vanishing and independent of $\mu$. Hence, the dual section in $\omega_X^\vee$ is non-vanishing. For smooth varieties, the canonical and dualizing sheaves are identical, $\omega = \omega^\vee$, so we get:

1That is, independent of $\mu$ up to a constant which proves to be $(-1)^\mu$: checked with Maple.
Proposition 3 On the varieties $X_A$, we have a global section of the dualizing sheaf given by
\[
\Omega = \frac{(-1)^\mu (2\pi i)^3 \text{Pf}(N_{[\mu_3\mu_4\mu_5\mu_6]})\Omega_0}{dp_{\mu_0} \wedge dp_{\mu_1} \wedge dp_{\mu_2}} = \text{Res} \left( \frac{(-1)^\mu \text{Pf}(N_{[\mu_3\mu_4\mu_5\mu_6]})\Omega_0}{p_{\mu_0}p_{\mu_1}p_{\mu_2}} \right). \tag{6}
\]
where $\Omega_0$ is the global section of $\omega_{\mathbb{P}^6(7)} \cong \mathcal{O}_{\mathbb{P}^6}$ given by

\[
\Omega_0 = \frac{x_0^7}{(2\pi i)^6} \cdot \prod_{i=1}^6 d\left( \frac{x_i}{x_0} \right). \tag{7}
\]
The general $X_A$ is smooth, making $\Omega$ a global section of the canonical bundle.

Actually, $\text{Pf}(N_{[\mu_3\mu_4\mu_5\mu_6]}) \neq 0$ specifies the appropriate component of $p_{\mu_0} = p_{\mu_1} = p_{\mu_2} = 0$.

3 The Orbifold Construction

There are maps $\sigma : e_i \mapsto e_{i+1}$ and $\tau : e_i \mapsto e_i w^k$ where $w = e^{2\pi i/7}$ and $(e_i)$ is a fixed basis for $E$, forming a group action on $E$. The commutator is multiplication with a constant, so in the projective setting, these two maps commute giving an abelian $7 \times 7$-group $G$: eg., it gives an action on $\mathbb{P}(E \wedge E)$. We take the family of 6-planes in $\mathbb{P}(E \wedge E) \cong \mathbb{P}^{20}$ such that these maps restrict to them: ie., $\text{Span}\{\sum_{i,j=k} y_{i-j}e_i \wedge e_j \}_{k \in \mathbb{Z}_7}$ or in matrix representation, $N = [x_{i+j}/y_{i-j}]_{i,j \in \mathbb{Z}_7}$, where we take $x_i$ to be coordinates on $\mathbb{P}^6$ and $y_i + y_{-i} = 0$. This gives a $\mathbb{P}^2$-family of 6-planes as parametrized by $[y_1 : y_2 : y_3]$, thus defining a $\mathbb{P}^2$-subfamily of $X_A$. These have double-points at the 49 points $[x_i]_{i \in \mathbb{Z}_7} \in \{g([y_i]_{i \in \mathbb{Z}_7]) | g \in G\}$.

For any 7-subgroup of $G$, there are 7 fixed-points in $\mathbb{P}^6$ under its action, and three lines in the $\mathbb{P}^2$ parameter space such that these fixed points lie in the corresponding varieties. We are free to choose any such subgroup, and any of the three lines, without loss of generality, as the normalizer of $G$ acts transitively on the eight triplets of lines.

Let $H$ be the subgroup generated by $\tau$, and choose the line $y_3 = 0$. We may then use the coordinate $y = y_2/y_1$ to parametrize our $\mathbb{P}^1$-family. We then have a matrix $N_y$ whose rank 4 locus defines a degree 14 dimension 3 variety $X_y \subset \mathbb{P}^6$. In addition to the 49 double-points, the 7 fixed-points under $\tau$ are also double-points. In general, these are the only singular points.\footnote{For convenience, $k$-forms should contain the coefficient $(2\pi i)^{-k}$. This places the closed forms in the integral cohomology.}

For $y = 0$ and $y = \infty$, the variety $X_y$ decomposes into 14 distinct 3-planes intersecting on the coordinate planes.

In addition to the line-triplet we have chosen, there are seven other equivalent line-triplets. These intersect our chosen line in 21 points: $y^{21} - 289y^{14} - 58y^7 + 1 = 0$. For these values of $y$, the variety gains 7 further double-points.

Using a construction similar to that of Candelas et. al.\footnote{This has been checked using Macaulay\footnote{for the case $y = 1$.}}], let $M_y = X_y/H$ by a minimal (canonical) desingularization of the quotient $[\mathbb{P}^6]$.\footnote{3}
The map $x_i \mapsto x_i w^{5i^2}$ in the normalizer has the same effect as $y \mapsto y w$. Hence, the natural parameter is $\phi = y^7$, and the manifold is denoted $M_\phi$.

To give a brief review of the definition (in matrix notation):

**Definition 4** Let $N$ be the skew-symmetric matrix $[x_{i+j} y_{i-j}]_{i,j \in \mathbb{Z}}$ where $y_i + y_{-i} = 0$, and $P = [p_i]$ the pfaffians of the $6 \times 6$ diagonal minors; denote by $X_Y$, $Y = [y_i]$, the zero locus of $P$.

For $y_3 = 0$, let $y = y_2/y_1$ and denote the variety $X_y$. Let $H = \langle \tau \rangle$ be the group acting on $X_y$ by $\tau: x_i \mapsto wx_i$. We take a minimal desingularization of $X_y/H$, parametrize this family by $\phi = y^7$, and denote the resulting family of threefolds $M_\phi$.

Gaining and resolving double-points corresponds to collapsing an $S^3$ to a point and then blowing it up to a $\mathbb{P}^1$. This increases the Euler-characteristic by 2, either by increasing $h^{1,1}$ and $h^{2,2}$ by one each or by reducing $h^{1,2}$ and $h^{2,1}$ by one each. The blow-ups are along codimension 1 surfaces going through the double-points, and each such blow-up provides us with an extra $(1,1)$-form. Neither of these processes, the collapsing and the blowing up, affect the dualizing sheaf as both processes are local: contained in a set with no codimension 1 subvariety.

The creation and resolving of the $49 + 7$ double-points thus increases the Euler-characteristic to 14. The action of $H$ has 14 fixed points: two on each $\mathbb{P}^1$ from the blowing up of the initial fixed-points. These quotient singularities can be desingularized without affecting the dualizing sheaf $\mathcal{O}$. The Euler characteristic of the desingularized quotient is given by Roan in [8] to be 98 using

$$\chi(V) = \sum_{g,h \in H} \chi(V^g \cap V^h)$$

for any smooth $V$, $V^g$ the fixed-point set in $V$ of $g$, $H$ an abelian group.

To see the effect on the betti numbers, we have to go in some greater detail as to the blow-ups. We may blow the variety up along the surfaces $S_i = \{x_i = x_{i-3} = x_{i+3} = x_{i-2} x_{i+2} - y^2 x_{i-1} x_{i+1} = 0\}$, $i \in \mathbb{Z}$, in any order. From this, $h^{1,1}$ is increased by 7. Hence, for $X_y$ we get $h^{1,1} = h^{2,2} = 8$, causing $h^{1,2} = h^{2,1} = 1$. This corresponds with the dimension of the parameter space which must therefore be the entire moduli-space.

The surfaces $S_i$ are invariant under $\tau$, hence, dividing $X_y$ with $H$ does not change $h^{1,1}$. By [1], the effect of dividing with the group $H$ and resolving the fixed-point singularities, increases $h^{1,1}$ and $h^{2,2}$ by 3 for each fixed-point, thus making $h^{1,1} = h^{2,2} = 50$.

The variety now being smooth, the trivial dualizing sheaf is again identical to the canonical sheaf, which must therefore be trivial too.

It should be pointed out that the resolution may not be unique. However, different resolutions will merely correspond to different parts of the A-model (Kähler structure related) moduli space: eg., a flop corresponds to changing the sign of one component of $H^{1,1}$, thereby moving the Kähler cone [1].

**Proposition 5** For general $y \in \mathbb{P}^1$, the manifolds $M_y = X_y/H$ are Calabi–Yau manifolds having $\chi(M_y) = 98$, $h^{1,1} = h^{2,2} = 50$, and $h^{1,2} = h^{2,1} = 1$; the global
section of the canonical sheaf inherited from $X_A$ as given by $\text{[3]}$. At the points $\phi = 0$ and $\phi = \infty$, the variety decomposes into 14 3-planes, and for $1 - 57\phi - 289\phi^2 + \phi^3 = 0$, where $y$ lies on an intersection between two special lines in the $\mathbb{P}^2$ parameter space, there is an extra double-point.

The families $M_y$ and $X_A$ thus look like good mirror candidates.

4 Mirror Symmetry

We now have a 1-parameter family of Calabi-Yau manifolds $M_\phi$ with a global section $\Omega(\phi)$ of the canonical bundle given. By the mirror symmetry conjecture, there is a special point in our moduli space corresponding to the ‘large radius limit’. Around this point, $H^3$ should have maximally unipotent monodromy. As $M_\phi$ degenerates into 14 3-planes for $\phi = 0$ (and for $\phi = \infty$) we will start off with this as the assumed special point.

Following Morrison $\text{[3]}$, there should be Gauss–Manin flat families of 3-cycles $\gamma_0, \gamma_1$, i.e. sections of $R_3\pi_*\mathcal{C}$, defined in a punctured neighborhood of $\phi = 0$ with $f_i(\phi) = \int_{\gamma_i(\phi)} \Omega(\phi)$, such that $f_0$ extends across $\phi = 0$ and $f_1/f_0 = g + \log \phi$ where $g$ extends across $\phi = 0$. The natural coordinate $t = t(\phi)$ is then given by $t = f_1/f_0$; i.e., the complexified Kähler structure on the mirror is $\omega = t\omega_0$ where $\omega_0$ is a fixed Kähler form (the dual of a line). As this enters only as $\exp \int \eta \omega$, we may use the coordinate $q = e^t = \phi e^g$.

The curve count on the mirror is arrived at using the mirror symmetry assumption: that the B-model Yukawa-coupling derived from the variation of complex structure (Hodge-structure) should be equal to the A-model Yukawa-coupling on the mirror. The A-model Yukawa-coupling is expressed in terms of the corresponding Kähler structure given by the natural coordinate and the number of rational curves in any curve class (i.e., of any given degree) by

$$\kappa_{\text{ttt}} = n_0 + \sum_{d=1}^{\infty} n_d d^d q^{d/1-q^d}. \tag{9}$$

The B-model Yukawa-coupling $\kappa_{\text{ttt}}$ may be defined as in $\text{[3]}$, by

$$\kappa_{\text{ttt}} = \kappa \frac{d}{dt} \frac{d}{dt} \frac{d}{dt} = \kappa \cdot \frac{d}{dt} \otimes \frac{d}{dt} \otimes \frac{d}{dt} = \int_{M_\phi} \hat{\Omega} \wedge \nabla^3 \hat{\Omega} \tag{10}$$

with $t$ the parameter on the moduli-space, $\frac{d}{dt}$ seen as a tangent vector on the moduli space, $\nabla$ the Gauss–Manin connection, and $\hat{\Omega} = \Omega/f_0$ the normalized canonical form. (In the following, I will write $\nabla_u = \nabla_{\frac{d}{dt}}$ for any parameter $u$.)

All of this can be determined from knowing the Picard–Fuchs equation $\text{[3]}$. The Picard–Fuchs equation is a differential equation on the parameter space whose solutions are $\int_{\gamma(\phi)} \Omega(\phi)$ for $\gamma$ Gauss–Manin flat sections on $R_3\pi_*\mathcal{C}$: i.e., $\gamma(\phi) = \sum_i u_i \nu_i(\phi)$ where $\nu_i(\phi) \in H_3(M_\phi, \mathbb{Z})$, $u_i \in \mathbb{C}$. This equation has order 4: i.e., for $f = \int_{\gamma} \Omega$, where $\gamma = \gamma(\phi) \in \Gamma(R_3\pi_*\mathcal{C})$ is any $\nabla$-flat section of 3-cycles, we have

$$\int_{\gamma(\phi)} \left( \sum_{i=0}^{4} A_i(\phi) \frac{d}{d\phi} \right)^4 \Omega = \sum_{i=0}^{4} A_i(\phi) D_i^4 f(\phi) = 0 \tag{11}$$
for $D_\phi = \phi \frac{d}{d\phi} = d/d\log \phi$ the logarithmic derivative. Maximally unipotent monodromy around $\phi = 0$ is equivalent to having $A_i(0) = 0$ for $i < 4$ and $A_4(0) \neq 0$.

First, I will find $\gamma_0$ and calculate $f_0$. From this, I will determine the Picard–Fuchs equation. Knowing the Picard–Fuchs equation, $f_1$ can be found as another special solution. Furthermore, the Yukawa coupling, $\kappa$, satisfies a differential equation expressed in terms of the $A$-coefficients.

5 The Pfaffian Quotient Near $\phi = 0$

For simplicity, all calculations are pulled back from the manifold $M_\phi$ to the variety $X_y \subset \mathbb{P}^6$. At $y = 0$, the variety $X_y \subset \mathbb{P}^6$ degenerates into 14 3-planes intersecting along coordinate axes, the group $H$ acting on each 3-plane. One of these planes is given by $x_4 = x_5 = x_6 = 0$. Let $\gamma_0(0)$ be the cycle given on this 3-plane (minus the axes) by $|x_i/x_0| = \epsilon$ for $i = 1, 2, 3$. We may extend this definition by continuity to a neighborhood of $y = 0$.

Rather than working with $\gamma_0$, it is more convenient to work with the 6-cycle $\Gamma$ on $\mathbb{P}^6 \setminus X_y$ given by $|x_i/x_0| = \epsilon$ for $i = 1, 2, 3$ and $|x_i/x_0| = \delta$ for $i = 4, 5, 6$, and view $\Omega$ as the residue of

$$\Psi = \Omega \wedge \frac{dp_{\nu_0}}{2 \pi i p_{\nu_0}} \wedge \frac{dp_{\nu_1}}{2 \pi i p_{\nu_1}} \wedge \frac{dp_{\nu_2}}{2 \pi i p_{\nu_2}} = (-1)^\nu \text{Pf}(N_{\nu_0\nu_1\nu_2\nu_3\nu_4\nu_5}) \cdot x_0^\gamma \prod_{i=1}^6 d \left( \frac{x_i}{x_0} \right) \quad (12)$$

for any permutation $\nu$ of $0, \ldots, 6$. We now get

$$f_0(\phi) = \int_{\gamma_0(\phi)} \Omega(\phi) = \int_{\Gamma} \Psi(\phi) \quad (13)$$

where the last integral is over a cycle which is independent of $\phi$.

In order to make the numerator as simple as possible, choose $\nu_1, \nu_2, \nu_3 = 0, 3, 4$. This makes $\text{Pf}(N_{\nu_1\nu_2\nu_3\nu_4\nu_5\nu_6}) = x_3x_4$. Setting $x_0 = 1$ for simplicity (or writing $x_i$ for $x_i/x_0$), the integral becomes

$$\int_{\Gamma} \frac{x_3x_4}{p_0p_3p_4} \cdot \prod_{i=1}^6 \frac{dx_i}{2 \pi i} = \int_{\Gamma} \frac{1}{\prod_{i=0,3,4}(1 - \sum_{j=1}^4 v_{i,j})} \cdot \prod_{i=1}^6 \frac{dx_i}{2 \pi i x_i} \quad (14)$$

where

$$[v_{i,j}]_{i=0,3,4} = \left[ \begin{array}{cccc} \frac{x_3x_4}{x_3^3} & y & x_3^2y & x_3^2 \frac{x_3x_4}{x_3^2} \\ \frac{x_3x_4}{x_3^2} & y & x_3^2y & x_3^2 \frac{x_3x_4}{x_3} \\ x_3^2x_4 & y & x_3^2x_4 & x_3^2 \frac{x_3x_4}{x_3} \\ x_3^2x_4 & y & x_3^2x_4 & x_3^2 \frac{x_3x_4}{x_3} \end{array} \right]. \quad (15)$$

Taking the power expansion of the right hand fraction in terms of $v_{i,j}$, the only terms that give a contribution are products $v^n = \prod_{i,j} v_{i,j}^m$ that are independent of the $x_i$. The ring of products of $v_{i,j}$ which do not contain $x_i$ is $\mathbb{C}[r_i]$ where (see
appendix for description of method for finding the $r_k$)

\[
\begin{align*}
& r_1 = v_{1,4}v_{2,3}v_{3,3} = -y^7 = -\phi \\
& r_2 = v_{1,2}v_{2,3}v_{3,4} = -y^7 = -\phi \\
& r_3 = v_{1,3}v_{2,4}v_{3,3} = -y^7 = -\phi \\
& r_4 = v_{1,2}v_{2,2}v_{3,1} = y^7 = \phi \\
& r_5 = v_{1,3}v_{2,1}v_{3,2}v_{3,3} = y^7 = \phi \\
& r_6 = v_{1,1}v_{2,1}v_{3,2}v_{3,3} = y^7 = \phi.
\end{align*}
\]

Instead of evaluating the sum over $v^n$, we may now evaluate the sum over $r^m$ including as weights the number of times the term $r^m = v^n$ occures. This makes the integral, using the appropriate correspondence between $m$ and $n$,

\[
\int \Psi(\phi) = \sum_{(m_i) \in \mathbb{N}_0^5} \sum_{m=\sum_i m_i} (-1)^m \Phi_m \prod_i (n_{i,1,n_{i,2},n_{i,3},n_{i,4}})
\]

\[
= \sum_{m_1,m_6,u_1,u_2 \in \mathbb{N}_0} \sum_{m_1+u_1+u_2} (-1)^{m_1} \phi^{m_1} \cdot \frac{m!}{m_1!m_6!u_1!u_2!(m-u_1)(m-u_2)}
\]

\[
\cdot \sum_{m_2+m_4=u_1} (-1)^{m_2} \frac{(m_2+m_4+m_6)!}{m_2!m_4!m_6!} \cdot \sum_{m_3+m_5=u_2} (-1)^{m_3} \frac{(m_3+m_5+m_6)!}{m_3!m_5!m_6!}
\]

\[
= \sum_{m_1,m_6,u_1,u_2 \in \mathbb{N}_0} \sum_{m_1+u_1+u_2} (-1)^{m_1} \phi^{m_1} \cdot \frac{(m_1)!^2 (m_2)!^2 (m_3)!^2 (m_4)!^2 (m_5)!^2}{m_1!m_6!u_1!u_2!}
\]

\[
= 1 + 5\phi + 109\phi^2 + 3317\phi^3 + 121501\phi^4 + \cdots
\]

This function, $f_0$, should be a solution to a Picard–Fuchs equation given by $\sum_{i=0}^4 A_i D^i f_0(\phi) = 0$, where $D_\phi = \frac{d}{d\phi}$ and $A_i$ are polynomials in $\phi$ with $A_i(0) = 0$ for $i < 4$. Entering general polynomials for $A_i$, we find a solution for $A_i = 5$:

\[
\sum_{i=0}^4 A_i D^i_\phi = (1 - 57\phi - 289\phi^2 + \phi^3)(\phi - 3)^2 D^4_\phi
\]

\[
+ 4\phi(\phi - 3)(85 + 867\phi - 149\phi^2 + \phi^3)D^3_\phi
\]

\[
+ 2\phi(-408 - 7597\phi + 2353\phi^2 - 239\phi^3 + 3\phi^4)D^2_\phi
\]

\[
+ 2\phi(-153 - 4773\phi + 675\phi^2 - 87\phi^3 + 2\phi^4)D_\phi
\]

\[
+ \phi(-45 - 2166\phi + 12\phi^2 - 26\phi^3 + 3\phi^4).
\]

This is the so called Picard–Fuchs operator.

Solving for $f_1(\phi) = f_0(\phi) \cdot (g(\phi) + \log \phi)$, we get $g(\phi) = \alpha + 14\phi + 287\phi^2 + \cdots$, where $\alpha$ is a constant. The natural coordinate is $t = g(\phi) + \log \phi$ or $q = e^t = c_2(\phi + 14\phi^2 + 385\phi^3 + \cdots)$ where $c_2 = e^{\phi}$. We then calculate the Yukawa coupling. This is a symmetric 3-tensor on the parameter space, $\mathbb{P}^1$, which will be globally defined but with poles. The Yukawa
coupling is given by \((5), (3)\)

\[
\kappa_{ttt} = \left( \frac{d\log \phi}{dt} \right)^3 \kappa_{\log \phi \log \phi} \log \phi = \left( \frac{d\log \phi}{dt} \right)^3 \int_{M_\phi} \tilde{\Omega} \wedge \nabla_3^\phi \tilde{\Omega} \\
= \left( \frac{d\log \phi}{dt} \right)^3 \frac{1}{f_0(\phi)} \int_{M_\phi} \Omega \wedge \nabla_3^\phi \phi \Omega. \tag{19}
\]

To move \(f_0\) to outside the differential, we use Griffiths transversality property which implies that \(\Omega \wedge \nabla_3^\phi \phi \Omega = 0\) for \(i < 3\).

The term \(\int_{M_\phi} \Omega \wedge \nabla_3^\phi \phi \Omega\) satisfies a differential equation \((5)\):

\[
\phi \frac{d}{d\phi} \log \left( \int_{M_\phi} \Omega \wedge \nabla_3^\phi \phi \Omega \right) = -\frac{A_3}{2A_4}. \tag{20}
\]

This gives us

\[
\int_{M_\phi} \Omega \wedge \nabla_3^\phi \phi \Omega = \frac{c_1(3-\phi)}{1-57\phi-289\phi^2-\phi^3} \tag{21}
\]

for some constant \(c_1\). The denominator may be seen to have zeros at three points in the parameter space. These are the points where the manifold has singularities: where our particular special line in the bigger parameter space \(P^2\) intersects other special lines, and, hence, has an additional double point coming from the seven extra double points on \(X_y\).

The final step is to express \(\kappa_{ttt}\) in terms of \(q\). Using the power series expansion \(q = q(\phi)\) and its inverse series giving \(\phi = \phi(q)\), and \(\frac{d\log \phi}{dt} = \frac{q}{\phi} \frac{d\phi}{dq}\), we may express \(\kappa_{ttt}\) as

\[
\kappa_{ttt} = \left( \frac{q}{\phi(q)} \frac{d}{dq} \phi(q) \right)^3 \frac{1}{f_0(\phi(q))^2} \cdot \frac{c_1(3-\phi)}{1-57\phi-289\phi^2-\phi^3} \\
= c_1 \left( 3 + 14 \frac{\phi}{c_2} + 714 \left( \frac{\phi}{c_2} \right)^2 + 24584 \left( \frac{\phi}{c_2} \right)^3 + 906122 \left( \frac{\phi}{c_2} \right)^4 + \cdots \right) \tag{22}
\]

In order that there be only non-negative integer coefficients in the last line, we set \(c_2 = 1\). Putting \(c_1 = 2m\), we get

\[
\kappa_{ttt} = m \cdot \left( 6 + 28 \frac{\phi}{1-q} + 175 \frac{2^3 \phi^2}{1-q} + 1820 \frac{3^3 \phi^3}{1-q} + 28294 \frac{4^3 \phi^4}{1-q} + \cdots \right). \tag{23}
\]

The actual value of \(m\) cannot be seen from this series alone. However, \(m\) is supposed to have a fixed value as determined by the value of the Yukawa coupling.

**Proposition 6** The manifold \(M_\phi\) has maximally unipotent monodromy around \(\phi = 0\), the Picard–Fuchs equation is given by \((18)\). Assuming \(c_2 = 1\) and \(c_1 = 2m\), the mirror has degree \(6m\), and the rational curve count is \(28m\) lines, \(175m\) conics, \(1820m\) cubics, etc.
As the general $X_A$ that was initially assumed to be the mirror, has degree 14, and the first term of the $q$-series of $\kappa_{III}$ gives the degree of the mirror to be a multiple of 6, this cannot be the case. However, the point $\phi = \infty$ remains to be checked.

There is another striking observation: the Picard–Fuchs equation is exactly the same as for the A-model of $G(2, 7) \subset \mathbb{P}^{20}$ intersected by a general $\mathbb{P}^{13}$ \footnote{4. This observation was made by Duco van Straten.}. In this case, $m = 7$.

6 The Pfaffian Quotient Near $\phi = \infty$

Initially, the Picard–Fuchs equation seems to be regular at infinity, which would be most surprising as $M_\infty$ degenerates into 14 3-planes just like $M_0$. However, global sections of the canonical bundle $\Gamma(\omega_{M_\phi})$ may be viewed as a line-bundle on the parameter space, and as such it is isomorphic to $O_{\mathbb{P}^1}(1)$. To see this, recall that the global section $\Omega$ was of degree $-7$ in $y$, hence, degree $-1$ in $\phi$. In order to get a global section of the canonical bundle near $\phi = \infty$, one should use $\tilde{\Omega} = \phi \cdot \Omega$. This modification and changing coordinate to $\tilde{\phi} = 1/\phi$ amounts to the change $D\phi \mapsto -D\tilde{\phi} - 1$ in the Picard–Fuchs operator, making it

$$
\sum_{i=0}^{4} \tilde{A}_i D^{4-i}_{\tilde{\phi}} = (1 - 289\tilde{\phi} - 57\tilde{\phi}^2 + \tilde{\phi}^3)(1 - 3\tilde{\phi})D^{4}_{\tilde{\phi}} + 4\tilde{\phi}(3\tilde{\phi} - 1)(143 - 57\tilde{\phi} - 1\tilde{\phi}^2)D^{3}_{\tilde{\phi}} + 2\tilde{\phi}(-212 - 473\tilde{\phi} + 725\tilde{\phi}^2 - 435\tilde{\phi}^3 + 27\tilde{\phi}^4)D^{2}_{\tilde{\phi}} + 2\tilde{\phi}(-69 - 481\tilde{\phi} + 159\tilde{\phi}^2 - 171\tilde{\phi}^3 + 18\tilde{\phi}^4)D_{\tilde{\phi}} + \tilde{\phi}(-17 - 202\tilde{\phi} - 8\tilde{\phi}^2 - 54\tilde{\phi}^3 + 9\tilde{\phi}^4).
$$

We now see that the monodromy is maximally unipotent around $\phi = \infty$.

We may now proceed as for the previous case, but calculating $\tilde{f}_0$ from the Picard–Fuchs equation rather than the opposite. This gives a Yukawa-coupling in terms of $\tilde{q}$:

$$
\kappa_{III} = c_1(1 + 42\tilde{q}/c_2) + 6958(\tilde{q}/c_2)^2 + \cdots
$$

where $c_1 = c_1 = 2m$: just enter $\phi = \infty$ into the Yukawa-coupling \footnote{5. Private communication. May be published by Ellingsrud, Strømme and Peskine soon.} after multiplying with $\phi^2$ owing to the transition to $\tilde{\Omega} = \phi \cdot \Omega$. Putting $\tilde{c}_2 = 1$, we get

$$
\kappa_{III} = m(2 + 84\tilde{q}/1 - \tilde{q}^2 + 1729\tilde{q}^2/1 - \tilde{q}^2 + 83412\tilde{q}^3/1 - \tilde{q}^2 + 5908448\tilde{q}^4/1 - \tilde{q}^2 + \cdots).
$$

**Proposition 7** The manifold $M_\phi$ has maximally unipotent monodromy around $\phi = \infty$, the Picard–Fuchs equation is given by (24). Assuming $\tilde{c}_2 = 1$ and $m = 7$ to give the mirror degree 14, the rational curve count is 588 lines, 12103 conic, 583884 cubics, etc.

The lines on the general pfaffian have been counted by Ellingsrud and Strømme\footnote{5. Private communication. May be published by Ellingsrud, Strømme and Peskine soon.} and is 588.
7 The Grassmannian $G(2,7)$ Quotient

Due to the equality between the B-model Picard–Fuchs operator at $\phi = 0$ for the pfaffian quotient and the A-model Picard–Fuchs operator for an intersection of $G(2,7) \subset P^{20}$ with a general $P^{13}$, it is natural to take a closer look at $G(2,7)$. In particular, it is possible to perform an orbifold construction on this which is ‘dual’ to that on the pfaffian.

The pfaffian quotient was constructed from an intersection between the general pfaffian in $P^{20}$ and a special family of 6-planes: $P^6_y$. We may take the family $P^6_y$ of 13-planes in $P(E^y \wedge E^y) \cong P^{20}$ dual to $P^6_y$, and take $Y_y = G(2,7) \cap P^{13} \subset P^{20}$. Again, we have a group action by $\tau : x_{i,j} \mapsto x_{i,j}u^{i+j}$ which restricts to this intersection, and the natural coordinate being $\phi = y^7$. The $\tau$-fixed points, $e_i \wedge e_{i+3}$, are double-point singularities, as are the images under $\tau$ of $(e_{i+1} - e_{i-1}) \wedge ((e_{i+3} - e_{i-3}) + y(e_{i-2} - e_{i+2}))$. Let $W_y$ be the desingularized quotient $Y_y/\tau$. This is a Calabi–Yau manifold $[2]$. I will proceed without going into the desingularization as this has no impact on the B-model.

To summarize the definition (in matrix notation):

**Definition 8** Let $U_y = [x_{i,j}]_{i,j} \in \mathbb{Z}_7$, $x_{i,j} + x_j, i = 0$, be the skew-symmetric matrix with $x_{i+4,i-4} = -yx_{i+1,i-1}$. (This amounts to specializing to the 13-planes $P^6_y$ dual to the $P^6_y$ used for the pfaffians, and giving a specific coordinate system.) Let $Y_y$ denote the rank 2 locus of $U_y$ in $P^{13}$. Divide this out with the group action generated by $\tau : x_{i,j} \mapsto x_{i,j}u^{i+j}$, take a minimal desingularization of this, parametrize the resulting family of threefolds by $\phi = y^7$ denoting it $W_\phi$.

In order to get an expression for the canonical form, we may look at an affine piece of $G(2,7)$ given by $u_1 \wedge u_2$ where $u_i = [u_{i,j}], i = 1, 2, j = 0, \ldots, 6$, and where $u_{1,0} = u_{2,2} = 1, u_{1,2} = u_{2,0} = 0$. The defining equations then become

$$u_{1,1}u_{2,i+1} - u_{1,1+i}u_{2,i} = y \cdot (u_{1,i-2}u_{2,i+3} - u_{1,i+3}u_{2,i-2}), \quad i \in \mathbb{Z}_7. \quad (27)$$

Now, as we have a complete intersection, we may define the canonical form $\Omega$ as the residue of

$$\Psi = \frac{\wedge_{i=1,3,4,5,6} du_{1,i} \wedge du_{2,i}}{(2\pi i)^{10} \prod_{i \in \mathbb{Z}_7} (u_{1,1}u_{2,i+1} - u_{1,1+i}u_{2,i} - y \cdot (u_{1,i-2}u_{2,i+3} - u_{1,i+3}u_{2,i-2}))}. \quad (28)$$

For $y = 0$, the variety decomposes. One of the components may be given in affine coordinates by $u_1 \wedge u_2$ where $u_1 = [1,0,0,0,0,0,0], u_2 = [0,0,1,2,3,2,4,2,5,0]$. We may define the 3-cycle $\gamma_0(0)$ by $|u_{2,j}| = \epsilon$ for $j = 3, 4, 5$, and extend this to a neighborhood: say, $|y| < \delta$. As for the pfaffian, we will rather use the 10-cycle $\Gamma$ in $P^{20}$ defined by $|u_{i,j}| = \epsilon$, where again $u_i = [u_{i,j}]$ with $u_{1,0} = u_{2,2} = 1, u_{1,2} = u_{2,0} = 0$. The actual choices of $\delta$ the $\epsilon_{i,j}$ will be made so as to make the quotients $v_{i,j}$ defined below sufficiently small, but will otherwise be of no importance.

We may now rewrite the residual form so as to suite our purpose of evaluating it as a power series in $y$:

$$\Psi = \frac{1}{\prod_i (1 - \sum_j v_{i,j})} \wedge_{i=1,3,4,5,6} \frac{du_{1,i} \wedge du_{2,i}}{(2\pi i)^{2} u_{1,i}u_{2,i}}. \quad (29)$$
where

\[ v_{1,1} = -y \cdot \frac{u_{1,5}u_{2,4}}{u_{2,1}}, \quad v_{1,2} = y \cdot \frac{u_{1,3}u_{2,5}}{u_{2,1}}, \]

\[ v_{2,1} = -y \cdot \frac{u_{1,6}u_{2,4}}{u_{1,1}}, \quad v_{2,2} = y \cdot \frac{u_{1,4}u_{2,6}}{u_{1,1}}. \]

\[ v_{3,1} = y \cdot \frac{u_{2,5}}{u_{1,3}}; \quad v_{4,1} = \frac{u_{1,3}u_{2,4}}{u_{1,4}u_{2,3}}; \quad v_{4,2} = y \cdot \frac{u_{1,1}u_{2,6}}{u_{1,4}u_{2,3}}; \quad v_{4,3} = -y \cdot \frac{u_{1,6}u_{2,4}}{u_{1,4}u_{2,3}} \]

\[ v_{5,1} = \frac{u_{1,4}u_{2,5}}{u_{1,5}u_{2,4}}; \quad v_{5,2} = -y \cdot \frac{1}{u_{1,5}u_{2,4}}; \quad v_{6,1} = \frac{u_{1,5}u_{2,6}}{u_{1,6}u_{2,5}}; \quad v_{6,2} = y \cdot \frac{u_{1,3}u_{2,1}}{u_{1,6}u_{2,5}}; \quad v_{6,3} = -y \cdot \frac{u_{1,1}u_{2,3}}{u_{1,6}u_{2,5}} \]

\[ v_{7,1} = y \cdot \frac{u_{1,4}}{u_{2,6}}. \]

In order that the power series expansion converge, we need \( \sum_j |v_{i,j}| < 1 \). In order to obtain this, set \( \epsilon_{1,i}/\epsilon_{2,i} < \epsilon_{1,j}/\epsilon_{2,j} \) for \( 3 \leq i < j \leq 6 \), and \( \delta \) sufficiently small.

If we look at the ring generated by the \( v_{i,j} \), the subring of elements that do not contain terms \( u_{i,j} \) is \( \mathbb{C}[r_i] \), where

\[ r_1 = v_{1,1}v_{2,1}v_{3,1}v_{4,2}v_{5,2}v_{6,2}v_{7,1} = y^7 = \phi \]

\[ r_2 = v_{1,2}v_{2,1}v_{3,1}v_{4,3}v_{5,2}v_{6,1}v_{6,3}v_{7,1} = -y^7 = -\phi \]

\[ r_3 = v_{1,1}v_{2,1}v_{3,1}v_{4,1}v_{4,3}v_{5,1}v_{5,2}v_{6,1}v_{6,3}v_{7,1} = y^7 = \phi \]

\[ r_4 = v_{1,1}v_{2,2}v_{3,1}v_{4,1}v_{4,3}v_{5,2}v_{6,3}v_{7,1} = -y^7 = -\phi. \]

For any monomial \( r^m = \prod_i r_i^{m_i} \), the corresponding \( u^n = \prod_{i,j} u_{i,j}^{n_{i,j}} \) appars \( \prod_i (n_{i,1} \ldots) \) number of times, \( n_i = \sum_j n_{i,j} \). The power series expansion for \( f_0 = \int_0^\Omega \) will then be given by

\[
\int \mathcal{G} = \sum_{(m_i) \in N_i^0} \sum_{m=0} \sum_{(n_i, \ldots)} (-1)^{m_1+4m_4} \phi^m \cdot \prod_{i=1}^7 (n_{i,1} \ldots) \]

\[ = \sum_{(m_i) \in N_i^0} (-1)^{m_1+4m_4} \phi^m \cdot (m_1) \cdot (m_2) \cdot (m_3) \cdot (m_4) \]

\[ = 1 + 5\phi + 109\phi^2 + 3317\phi^3 + 121501\phi^4 + 4954505\phi^5 + \ldots \]

which may be recognized as exactly the same series as for the pfaffian quotient. Hence, the Picard–Fuchs operator etc. all become the same as for the pfaffian quotient.

The global sections of the canonical sheaf again forms a \( \mathcal{O}_{\mathbb{P}^1(1)} \) line-bundle on the \( \mathbb{P}^1 \) parameter space. Hence, this grassmannian quotient has the same Picard–Fuchs operator at \( \phi = \infty \) as the pfaffian quotient.

**Proposition 9** The B-models of \( M_y \) and \( W_y \) have the same Picard–Fuchs operator. Hence, the Yukawa-coupling may at most differ by a factor.

Of course, it is natural to conjecture that the Yukawa-couplings are equal, making the B-models isomorphic.
8 Comments on the Results

Apparently, there is a strong relation between the varieties defined by the pfaffians and the grassmannian $G(2, 7)$. The B-models of the $M_y$ and $W_y$ are isomorphic, and according to mirror symmetry and assuming that we actually have the mirrors, the A-models of the general pfaffian and general $G(2, 7)$ sections should also be isomorphic, and vice versa. It may of course be possible that we have found models with the same B-model but different A-models, in which case they would not be mirrors.

Assuming that we actually have mirror symmetry, it would appear that varying the complex structure on $M_y$ or $W_y$ leads to a transition from the Kähler structure on the pfaffian section $X_A$ to that of the grassmannian section $Y_A$.

**Conjecture 10** The pairs $M_y + W_y$ is the mirror family of $X_A + Y_A$ where $M_y$ and $W_y$ (resp. $X_A$ and $Y_A$) form different parts of the A-model (Kähler) moduli space.

It is worth noting that the varieties $X_A$ and $Y_A$ cannot be birationally equivalent. As $h^{1,1} = 1$, this has a unique positive integral generator (the dual of a line); if birational, these two must correspond up to a rational factor. Integrating the third power of this over the variety gives the degree; the ratio of the degrees would then be the third power of a rational number, which is not possible for $42/14 = 3$.

There may be rational 3-to-1 map though.

A Finding Generators of Subring

Assume that we have a list of variables $x_i$, $i = 1, \ldots, n$, and Laurent-monomials $v_j = \alpha_j \prod_i x_i^{a_{j,i}}$, $j = 1, \ldots, m$, with $a_{j,i} \in \mathbb{Z}$. We wish to find $r_k = \prod_j v_j^{b_{k,j}}$ such that $r_k(x)$ is independent of $x_i$ and generates the ring of polynomials in $v_j(x)$ independent of $x_i$ (or some extension of this ring).

An optimistic approach is simply the find a set of linearly independent vectors with integer coefficients generating the kernel of the matrix $A = [a_{j,i}] : \mathbb{C}^n \rightarrow \mathbb{C}^n$. In the nicest cases, in particular in the two cases that we are treating, one may even find such vectors with non-negative integer coefficients. If these vectors are $b_k = [b_{k,j}]_j$, $k = 1, \ldots, m - n$, define $r_k = \prod_j v_j^{b_{k,j}}$.

More generally, there is a risk that some of the $r_k$ will not be monomials, but Laurent monomials: some $b_{k,j}$ will be negative. These can still be used as generators, but in the sum over monomials in $r_k$, only those which are monomials in $v_j$, i.e. without negative powers of $v_j$, are considered.
