Abstract

The mother functions for the eigenfunctions of the Koroteev-Shakirov version of quantum double-elliptic (Dell) Hamiltonians are actually infinite series in Miwa variables, very similar to the recent conjecture due to J. Shiraishi. Further studies should explain numerous unclarified details and thus resolve the long-standing puzzle of explicitly constructing a Dell system, the top member of the Calogero-Moser-Ruijsenaars system, where the $PQ$-duality is fully explicit at the elliptic level.

1 Introduction

The systems with both coordinates and momenta lying on two independent tori called double elliptic systems (Dell) were introduced in [1] for a description of the 6$d$ Seiberg-Witten theories containing the adjoint matter hypermultiplet. A celebrated property of these systems is self-duality [1–6], which, in nowadays terms, is often referred to as the spectral (self)-duality [7]. A relation of these systems with topological strings and extension to the 6$d$ Nekrasov functions was later discussed in [8]. Moreover, in [9], using solutions to the elliptic KZ equations, we discussed the modular properties of these 6$d$ gauge theories described by Dell systems and derived in [10].

One of the problems with the Dell systems is that they are unambiguously defined only in the $SU(2)$ case (two particles), while the $SU(n)$ ($n$-particle) generalization admits two formulations [5] and [11], and the relation between these remains unclear so far. Calculations are very tedious: constructing manifest formulas is a non-trivial problem even in the classical case [12], the Nekrasov ($\Omega$-background) case is even more involved (in Seiberg-Witten theory, these formulas are supposed to describe the intermediate case of the Nekrasov-Shatashvili limit [13] on the way to the full-fledged Dell deformation of Nekrasov functions [8]). A new suggestion for the Dell Hamiltonians was recently presented in [15], it looks close to the old proposal of [11]. Even if not fully adequate (see below), its simple form gives an opportunity to further develop the technique of Dell studies, which will be the goal of the present paper.

In [15], only a simple example of the eigenfunctions was considered, in the form of a few lowest terms of expansion in one of the elliptic parameters, and for just the simplest (fundamental) representation of $SL(n)$. We are not going to literally extend this result to higher representations, because exact status of the KS Hamiltonians is still unclear. Instead, we concentrate on a general approach to the eigenfunction problem. It could seem very hard, but luckily this is not the case. The problem is drastically simplified if one considers not the Macdonald-like functions per se, but their much simpler continuation from the Young diagrams $\lambda$, which label the representations of $SL(n)$ to arbitrary values of the spectral parameters $y$, [16]. Such a function $M\{\vec{x}|\vec{y}\}$ with the property

$$M\{y_i = q^{\lambda_i} t^{\mu-n-i}|x_i\} = Mac_{\lambda}[x_i], \quad i = 1, \ldots, n$$

was nicknamed mother function in [17] (see also earlier papers [18]), where an elliptic (rather than generic Dell) version was considered and related to the theory of elliptic quantum toroidal algebras [19]. The main emphasize

Here is the variable $x$ momenta dependence of classical free Hamiltonians [1, 6]:

$$\hat{H}_x \cdot \Psi_\lambda(x) = E(\lambda) \Psi_\lambda(x)$$

then the dual Hamiltonian acts on the variable $\lambda$:

$$\hat{H}_\lambda^D \cdot \Psi_\lambda(x) = E^D(x) \Psi_\lambda(x)$$

Here $E$ and $E^D$ are some fixed functions of the variables $x$ and $\lambda$ accordingly. These functions are given by the momenta dependence of classical free Hamiltonians [16]:

$$E(\lambda) = \hat{H}_x^{free} \bigg|_{\partial_x \to \lambda}$$

In the case of many-body integrable system there are several coordinates $x_i$, $i = 1, ..., n$ and the corresponding $\lambda_i$ are associated with the separated variables – for systems which allow such separation. Integrability implies that in this case there are $n$ commuting Hamiltonians and $n$ dual Hamiltonians. In this context one naturally considers the eigenfunction $\Psi_\lambda(x)$ as a function of the two continuous variables $x$ and $\lambda$. Such a function serves as a reference example of the mother function. In the case of the Hamiltonians from the Calogero-Moser-Ruijsenaars-Shneider family, the most informative are the Hamiltonians of the Dell system, which are elliptic both in the coordinates and in momenta, and are self-dual, i.e. $H_k = H_k^D$, and their eigenfunctions are our main concern in this paper.

The main unresolved problem with this approach (seen already at the classical level) is that it seems not to directly reproduce the most interesting version of the Dell Hamiltonians in [11, 12, 22]. The claim in those papers was that in order to reflect the symplectic geometry of the problem and lead to explicit $PQ$-duality, the period matrices of the underlying Seiberg-Witten spectral curves should be dynamical (momentum) variables rather than just constants. This problem is basically ignored (though mentioned) in [15], which suggested to study just naive double-periodic Hamiltonians with no clear relation to the $PQ$-duality, but our new conjecture that the eigenfunctions can be made from (extension of) the self-dual Shiraishi functions could restore the relation. Still, the puzzle of dynamical period matrices persists, though it is a separate problem to find their quantization (Baxter $Q$-operators), which is straightforward with the naive choice of [15]. The resolution of all these problems can be the original suggestion of [11] to use the projection method and obtain a dynamical period matrix at genus $n - 1$ from a constant one at genus $n$. The crucial point here should be a peculiarly simple geometry of the Dell spectral curve, which is a simple junction of a few tori. Another task is a further generalization from the naive Dell system [1], related to quantum toroidal algebras, to arbitrary systems of Bethe-anzatz roots associated with arbitrary quivers and Nakajima varieties [24], of which the instanton moduli space is a simple example.
Plan of the paper. Below, we briefly repeat the basics of the Shiraishi-series theory of mother functions and then discuss their possible role as eigenfunctions of the Koroteev-Shakirov Hamiltonians. We consider in more details the simplest two-particle case \( n = 2 \), while the \( n \)-particle case in terms of the Shiraishi functions has to be understood as a representation in terms of separated variables of the Dell eigenfunctions. Then, in two Appendices, we show the relation of the Shiraishi function to the partition function of supersymmetric gauge theories. We expect both relations are consequences of the relation of Dell integrable system to six dimensional supersymmetric gauge theory, and, in this sense, they provide another, more physical evidence that the (extension of) Shiraishi function solves the quantum Dell system. These relations also reveal a geometric representation of theoretical meaning of the Shiraishi function. It is desirable to understand the Shiraishi function from the representation theory of the Ding-Iohara-Miki (DIM, quantum toroidal) algebra.

Notation. We define the odd \( \theta \)-function

\[
\theta_p(z) := \frac{1}{\sqrt{z}} (z;p)_\infty (p/z;p)_\infty (p;p)_\infty = \frac{1}{\sqrt{z}} \sum_{k \in \mathbb{Z}} (-1)^k z^k p^{k^2/2-k/2}
\]

and the even \( \theta \)-function

\[
\theta_p^{(e)}(z) := \sum_{k \in \mathbb{Z}} z^k p^{k^2}
\]

with the properties

\[
\theta_p(z) = -\theta_p(z^{-1}), \quad \theta_p^{(e)}(z) = \theta_p^{(e)}(z^{-1}), \quad \theta_p^{(e)}(z/w) = z \theta_p^{(e)}(1/(zw))
\]

Here the Pochhammer symbol is

\[
(x; q)_p := \prod_{n=0}^{p-1} (1 - q^n x) = \frac{(x; q)_\infty}{(q^n x; q)_\infty}
\]

and

\[
(x; q_1, q_2)_\infty := \prod_{n,m=0}^{\infty} (1 - q_1^n q_2^m x)
\]

In the standard notation of [28, 29], \( \theta_p^{(e)}(z) = \theta_3(v, \tau) = \theta_{00}(v, \tau) \) with \( p = e^{\pi i \tau}, z = e^{2\pi i v} \), while changing the \( \theta \)-function argument \( z \rightarrow \frac{z}{p} \) (see section 5) makes it \( \theta_2 = \theta_{10} \).

2 Mother functions

To understand the notion of mother function, one should begin from the case of Schur polynomials. In \( x \)-variables, they are extremely simple, for the Young diagram \( R = \{ R_1 \geq R_2 \geq \ldots \} \)

\[
\text{Schur}_R[x_1, \ldots, x_n] = \sum_{\sigma \in S_n} (-)^\sigma \prod_{i=1}^n x_i^{R_{\sigma(i)}+n-i} \prod_{i<j} (x_i - x_j)
\]

For symmetric representations we get just

\[
x_1^{R_1+1} x_2^{R_2} - x_1^{R_1} x_2^{R_2+1} \quad \frac{1}{x_1 - x_2} = x_1^{R_1} x_2^{R_2} \cdot \frac{1 - \left( \frac{x_2}{x_1} \right)^{R_1+1-R_2}}{1 - \frac{x_2}{x_1}}
\]

An obvious analytic continuation from integer to arbitrary \( R \) is provided by just the same expression, and there is an explicit symmetry \( \log x_i \) and \( R_i = \log y_i + i - n \); after division by an \( R \)-dependent factor [10] becomes

\[
\text{Schur}_R[x_1, \ldots, x_n] \sim \sum_{\sigma \in S_n} (-)^\sigma \prod_{i=1}^n e^{\log x_i \log y_i} \prod_{i<j} (x_i - x_j)(y_i - y_j)
\]
However, with this continuation the powers of \( x \)-variables can be non-integer. An alternative continuation, which
is assumed in the definition of mother function leaves all the powers integer, but converts a finite polynomial into an
infinite series. The idea is to take
\[
\frac{1 - x^{R+1}}{1 - x} = \sum_{k=1}^{R} x^k \rightarrow \lim_{\epsilon \to 0} \left\{ \sum_{k=0}^{\infty} \frac{\Gamma(k - R)}{\Gamma(-R)} \frac{\Gamma(-R + \epsilon)}{\Gamma(k - R + \epsilon)} x^k \right\}
\] (13)
The r.h.s. is a hypergeometric function \(_1F_1\), which can be bosonised by the method of [30], but we do not need these
details here. What is important, at integer \( R \), only the first \( R + 1 \) items in the sum are non-vanishing,
while, at non-integer \( R \), one gets an infinite sum with \( R \)-independent unit coefficients. Note that the function
becomes a symmetric function of \( x_i \) only at integer \( R_i \) and with the common factor \( \prod_{i=1}^{n} x_{R_i+1} \) inserted.

This singular-looking construction gets automatically regularized already in the case of Macdonald polynomials,
where \( \epsilon \) is no-longer vanishing, but is rather equal to \( \log(q/t) \), thus no limits are needed, and the
coefficients, while still vanishing at appropriate integer \( R_i \), become smooth functions of \( R_i \). This continues
to work nicely when the Macdonald polynomials are further deformed to elliptic Shiraishi series and their
double-elliptic generalizations.

3 Noumi-Shiraishi representation of Macdonald polynomials

We continue with the simplest healthy example of the mother function: the case of ordinary Macdonald polynomials.
This example was described in detail in [31].

Suppose \( t^k \not\in q^Z \) for \( k = 1, \ldots, n - 1 \). For \( i, j = 1, \ldots, n \) define a power series
\[
P_n(x_i, y_i|q, t) := \sum_{m_{ij}} C_n(m_{ij}, y_i|q, t) \prod_{1 \leq i < j \leq n} \left( \frac{x_{ij}}{x_i} \right)^{m_{ij}}
\] (14)
where \( m_{ij} = 0 \) for \( i \geq j \), \( m_{ij} \in \mathbb{Z}_{\geq 0} \),
\[
= \prod_{k=2}^{n} \prod_{1 \leq i < j \leq k} \left( \frac{\sum_{a \geq k} (m_{ia} - m_{ja}) y_j/y_i; q}{\sum_{a \geq k} (m_{ia} - m_{ja}) q y_j/y_i; q} \right)^{m_{ik}} \prod_{k=2}^{n} \prod_{1 \leq i < j < k} \left( \frac{q^{-m_{jk} + \sum_{a \geq k} (m_{ia} - m_{ja})} y_j/y_i; q}{q^{-m_{jk} + \sum_{a \geq k} (m_{ia} - m_{ja})} y_j/y_i; q} \right)^{m_{jk}}
\] (15)
This \( P_n(x_i, y_i|q, t) \) solves the eigenvalue problem
\[
\hat{D}(u) \cdot x^\lambda P_n(x_i, y_i|q, t) = \prod_{i=1}^{n} (1 - uy_i) \cdot x^\lambda P_n(x_i, y_i|q, t)
\] (16)
where \( \lambda \) is a set of complex parameters defined through \( q^{\lambda_i} := y_i t^{n-i} \) and
\[
\hat{D}(u) := \sum_{r} (-u)^r \hat{H}_r
\] (17)
is the generating function of the Ruijsenaars Hamiltonians \( \hat{H}_r \),
\[
\hat{H}_r := t^{n(n-1)/2} \sum_{|l|=r \in I, \not\in I} \prod_{i \not\in I} \frac{t x_i - x_j}{x_i - x_j} \prod_{i \in I} \hat{T}_{q, x_i}
\] (18)
where \( \hat{T}_{q, x_i} f(x_1, \ldots, x_i, \ldots, x_n) := f(x_1, \ldots, q x_i, \ldots, x_n) \).

With the choice \( y_i = q^{R_i} t^{n-i} \), the infinite series [14] becomes a Laurent, polynomial proportional to the
Macdonald polynomial for the partition \( R \) with \( l_R = n \),
\[
\text{Mac}_n(x_i; q, t) = x^{R_i} P_n(x_i, q^{R_i} t^{n-i}|q, t)
\] (19)
Limit to the Schur polynomials. As already mentioned, the limit of this representation of the Macdonald polynomials to the Schur polynomials is not naive, since naively the mother function at \(t = q\) does not depend on \(y_i\) at all. The role of the numerator of the first factor in (14) is that, when specializing to the Macdonald point \(y_i = q^{n-i}t^{n-i}\), it selects out the domain of values of variables \(m_{ij}\): the factor

\[
\prod_{k=2}^{n} \prod_{1 \leq i < j \leq k} \left( q^{\sum_{a > k} (m_{ia} - m_{ja})} t y_j / y_i q \right)_{m_{ij}}^\text{(20)}
\]

is non-vanishing iff non-vanishing is the factor with \(j = i + 1\), i.e. \(0 \leq m_{ik} \leq R_i - R_{i+1} - \sum_{a > k} (m_{ia} - m_{i+1,a})\) for all \(1 \leq i < k, 1 < k \leq n\). However, if one immediately puts \(t = q\) in (15), this numerator does not work this way any longer. Hence, in contrast to the Macdonald case, when one can ascribe arbitrary complex values to the variables \(y_i\), one can not consider the Schur polynomial outside the values associated with a concrete Young diagram. In this case, one has to restrict the admissible values of \(m_{ij}\) by hands, and only after this put \(t = q\), what leads to \(C_n(m_{ij}, y_i|q,t) = 1\). Thus, one obtains in the Schur limit, instead of (14), the expression

\[\text{Schur}_R(x_i) := x^R \cdot \sum_{m_{ij} \in A_R 1 \leq i < j \leq n} \left( \frac{x_j}{x_i} \right)^{m_{ij}}\] (21)

where \(A_R\) is a set of \(m_{ik} : 0 \leq m_{ik} \leq R_i - R_{i+1} - \sum_{a > k} (m_{ia} - m_{i+1,a})\) for all \(1 \leq i < k, 1 < k \leq n\).

Parameterizing \(m_{ij}\) by Young diagrams. The formulas for \(A_R\) in the previous paragraph suggest to introduce, instead of \(m_{ij}\),

\[\mu_i^{(k)} := R_i - \sum_{a > k} m_{ik}, \quad i = 1, \ldots, k\] (22)

Then, the conditions defining \(A_R\) are nothing that a requirement for \(\mu^{(j)}\) to be a set of Young diagrams (with \(j\) lines, \(j = 1, \ldots, n\)). In fact, formula \(\mu^{(j)}\)

\[m_{ij} = \mu_i^{(j)} - \mu_i^{(j-1)}\] (23)

and the initial conditions \(\mu_i^{(n)} = R_i\), which one additionally imposes when associating \(P(x_i, y_i|q,t)\) with the Macdonald polynomial. Generally, it is sufficient to define \(\mu_i^{(j)}\) with \(\mu^{(j)}\).

In particular, with this definition \(\mu^{(j)}\), the \(x\)-dependent factor in (14) can be rewritten in the form

\[\prod_{1 \leq i < j \leq n} \left( \frac{x_j}{x_i} \right)^{m_{ij}} = \prod_{1 \leq i < n} \left( \frac{x_{i+1}}{x_i} \right)^{\sum_{a=1}^{i} (\mu_a^{(n)} - \mu_a^{(1)})}\] (24)

Choosing the initial conditions \(\mu_i^{(n)} = 0\), one arrives at

\[\prod_{1 \leq i < j \leq n} \left( \frac{x_j}{x_i} \right)^{m_{ij}} = \prod_{1 \leq i < n} \left( \frac{x_{i+1}}{x_i} \right)^{-\sum_{a=1}^{i} \mu_a^{(j)}} = \prod_{1 \leq i < n} \prod_{a=1}^{i} \left( \frac{x_{i+1}}{x_i} \right)^{-\mu_a^{(j)}}\] (25)

Note that one can define \(\Lambda_j^{(j)} := -\mu_j^{(j)}\) so that \(m_{ij} = \Lambda_j^{(i)} - \Lambda_j^{(i-1)}\), and the condition of non-negativity of \(m_{ij}\) would just mean that \(\Lambda^{(i)}\) is a Young diagram. However, there is still an additional condition for \(\Lambda_j^{(j)}\) that \(j \leq i\) (see (24)). In order to remove it for having an unconstrained set of the Young diagrams, we define, for future convenience, \(\lambda_j^{(i)} := \Lambda_j^{(i)} - \Lambda_j^{(i-1)}\) so that the additional condition becomes just \(j \geq 1\). With this definition, the previous factor can be rewritten as

\[\prod_{1 \leq i < j \leq n} \left( \frac{x_j}{x_i} \right)^{m_{ij}} = \prod_{b=1}^{n-1} \prod_{a=1}^{n-b} \left( \frac{x_{a+b}}{x_{a+b-1}} \right)^{\lambda_a^{(b)}}\] (26)

Note that the initial conditions \(\mu_i^{(n)} = 0\) reads that the number of lines of the Young diagram \(l_{\lambda_i^{(i)}} \leq n - i\). Note also that \(A_R\) in these variables is:

\[A_R : \quad \lambda_j^{(i)} \leq R_i - R_{i+1} + \lambda_j^{(i+1)}, \quad 1 \leq j \leq n - i\] (27)
Examples

$n = 2$ The coefficient (15) is

\[ C_2(m_{12}, y_1, y_2 | q, t) = \frac{(ty_2/y_1 | q, t)_{m_{12}}}{(yy_2/y_1 | q, t)_{m_{12}}} \left( \frac{q^2}{t^m} \right)^{m_{12}} \]

The Macdonald polynomial associated with the 2-line Young diagrams is

\[ \text{Mac}_{(n_1, n_2)}(x_1, x_2; q, t) = x_1^{n_1} x_2^{n_2} \sum_{m=0}^{R_1-R_2} \frac{(q^{R_2-R_1+1} | t; q)_m}{(q; q)_m} \left( \frac{x_2}{tx_1} \right)^m \]

and the corresponding Schur polynomial is

\[ \text{Schur}_{(n_1, n_2)}(x_1, x_2) = x_1^{n_1} x_2^{n_2} \sum_{m=0}^{R_1-R_2} \left( \frac{x_2}{x_1} \right)^m \]

$n = 3$ The coefficient (15) is (notice a misprint in (31))

\[ C_3(m_{12}, m_{13}, m_{23}, y_1, y_2, y_3 | q, t) = \frac{(q^{m_{13}-m_{23}} y_2/y_1 | q)_{m_{13}}}{(q^{m_{13}-m_{23}} y_2/y_1 | q)_{m_{13}}} \frac{(ty_2/y_1 | q)_{m_{13}}}{(ty_2/y_1 | q)_{m_{13}}} \frac{(ty_3/y_1 | q)_{m_{13}}}{(ty_3/y_1 | q)_{m_{13}}} \times \frac{(q^{m_{23}} y_2/y_1 | q)_{m_{13}}}{(q^{m_{23}} y_2/y_1 | q)_{m_{13}}} \frac{(q | t)_{m_{13}}}{(q | t)_{m_{13}}} \frac{(q | t)_{m_{23}}}{(q | t)_{m_{23}}} \]

The Macdonald polynomial associated with the 3-line Young diagrams is

\[ \text{Mac}_{(n_1, n_2, n_3)}(x_i; q, t) = x_1^{n_1} x_2^{n_2} x_3^{n_3} \sum_{m=0}^{R_1-R_2} \sum_{m_{23}=0}^{R_2-R_3} \sum_{m_{13}=0}^{R_1-R_2} C_3(m_{12}, m_{13}, m_{23}, t^2 q R_1, t^2 q R_2, q R_3 | q, t) \times \left( \frac{x_2}{x_1} \right)^{m_{12}} \left( \frac{x_3}{x_1} \right)^{m_{13}} \left( \frac{x_3}{x_2} \right)^{m_{23}} \]

and the corresponding Schur polynomial is

\[ \text{Schur}_{(n_1, n_2, n_3)}(x_i) = x_1^{n_1} x_2^{n_2} x_3^{n_3} \sum_{m_{13}=0}^{R_1-R_2} \sum_{m_{23}=0}^{R_2-R_3} \sum_{m_{13}=0}^{R_1-R_2} \left( \frac{x_2}{x_1} \right)^{\lambda_{1}^{(1)}} \left( \frac{x_3}{x_1} \right)^{\lambda_{1}^{(2)}} \left( \frac{x_3}{x_2} \right)^{\lambda_{2}^{(1)}} \left( \frac{x_2}{x_1} \right)^{\lambda_{2}^{(2)}} \]

This same expression in the $\lambda^{(i)}$-variables is

\[ \text{Schur}_{(n_1, n_2, n_3)}(x_i) = x_1^{n_1} x_2^{n_2} x_3^{n_3} \sum_{\lambda_{1}^{(2)}=0}^{R_2-R_3} \sum_{\lambda_{2}^{(1)}=0}^{R_1-R_2} \sum_{\lambda_{1}^{(1)}=0}^{R_1-R_2} \left( \frac{x_2}{x_1} \right)^{\lambda_{1}^{(1)}} \left( \frac{x_3}{x_1} \right)^{\lambda_{2}^{(1)}} \left( \frac{x_3}{x_2} \right)^{\lambda_{2}^{(2)}} \]

4 Shiraishi functions

Now we are ready to describe the double deformation of the Noumi-Shiraishi representation of the Macdonald polynomials, which was proposed by J. Shiraishi [23]. Define

\[ \mathcal{Q}_n(x_i; p | y_i; s | q, t) := \prod_{\lambda^{(i)} = 1}^{n} \prod_{i=1}^{n} \frac{N_{\lambda^{(i)}}^{(i)}(t y_j / y_i | q, s)}{N_{\lambda^{(i)}}^{(i)}(y_j / y_i | q, s)} \prod_{b=1}^{n} \prod_{i=1}^{n} \left( \frac{p x_{b+i} + b}{t x_{a+b}} \right)^{\lambda_{a}^{(b)}} \]

where \{\lambda^{(i)}\}, i = 1, \ldots, n is a set of $n$ partitions, we assume that $x_{i+n} = x_i$, and

\[ N_{\lambda^{(i)}}^{(j)}(u | q, s) := \prod_{j=1}^{n} \left( u q^{-\mu_i + \lambda_{j}^{(i+1)}} s^{-j-1} - q \right)^{\lambda_j^{(i+1)}} \prod_{j=1}^{n} \left( u q^{\lambda_{j}^{(i+1)}} s^{-j-1} - q \right)^{\mu_j^{(i+1)}} \]

This is what has to do with an eigenfunction of the quantum Dell Hamiltonian [15]. \mathcal{Q}(x_i; p | y_i; s | q, t) is a symmetric function w.r.t. simultaneous permutations of the pairs $(x_i, y_i)$, however, it is not a symmetric function.
of \(x_i\) only. In order to give rise to a symmetric function of \(x_i\), one has to choose this time \(y_i = q^{R_i(t)} s^{-i}\). Then, the function
\[
\mathcal{R}(x_i|p, s|q, t) := x^R \cdot \mathcal{P}_n(p^{n-i}x_i; p|q^{R_i(t)} s^{-i}; s|q, \frac{q}{t})
\] (37)
is a symmetric function.

**Dualities.** J. Shiraishi has conjectured [23] two duality formulas generalizing the corresponding duality formulas for the ordinary Macdonald polynomials:
\[
\mathcal{P}_n(x_i; p|y_i; s|q, t) = \mathcal{P}_n(y_i; s|x_i; p|q, t)
\] (38)
and Poincare duality
\[
\mathcal{P}_n(x_i; p|y_i; s|q, t) = \mathcal{P}_n(x_i; p|y_i; 0|q, \frac{q}{t})
\] (39)
Note that \(\mathcal{P}_n(x_i; p|y_i; s|q, t) = \prod_{1 \leq i < j \leq n} \frac{(p^{j-i} q x_j / x_i; q, p^n)_{\infty}}{(p^{j-i} t x_j / x_i; q, p^n)_{\infty}} \prod_{1 \leq i \leq n} \frac{(p^{n-j+i} q x_j / x_i; q, p^n)_{\infty}}{(p^{n-j+i} t x_j / x_i; q, p^n)_{\infty}}\)
(40)

**The limit to the elliptic Ruijsenaars system.** Another important conjecture by J. Shiraishi deals with the limit to the elliptic Ruijsenaars system. That is, let \(\xi(p|y_i; s|q, t)\) be the constant term of \(\mathcal{P}_n(x_i; p|y_i; s|q, t)\) w.r.t. \(x_i\):
\[
\xi(p|y_i; s|q, t) := \sum_{\lambda^{(i)}} \prod_{i,j=1}^n N_{\lambda^{(i)}} (y_j / y_i | q, s) \left( \frac{p}{t} \right)^{\lambda} (41)
\]
where we have introduced the notation: \(|\lambda| := \sum_{b} |\lambda^{(b)}|\), \(m_i := \sum_{a+b+i \equiv 0 \mod n} (\lambda^{(a)} - \lambda^{(b+1)})\) (i.e. \(|\lambda| = 0 \mod n\)). Then, the elliptic counterpart of the Macdonald polynomial is the function (the naive limit of [35] at \(s = 1\) is singular)
\[
\mathcal{P}_n(x_i; p|y_i; q, t) := \xi(p|y_i; s|q, t)^{-1} \cdot \mathcal{P}_n(x_i; p|y_i; s|q, t)_{|s=1}
\] (42)
It is conjectured [23] to be the eigenfunction of the elliptic Ruijsenaars Hamiltonian:
\[
\hat{D}_1 \cdot x^{\lambda} \mathcal{P}_n(p^{n-i}x_i; p|y_i; q, \frac{q}{t}) = \Lambda(y_i|p|q, t) \cdot x^{\lambda} \mathcal{P}_n(p^{n-i}x_i; p|y_i; q, \frac{q}{t}),
\]
\[
\hat{D}_1 := i^{n/2} \sum_{i=1}^n \prod_{j \neq i} \frac{\theta^{p^n}(t x_i / x_j)}{\theta^{p^n}(x_i / x_j)} \hat{T}_{q,x_i}
\] (43)
Here again, \(\lambda\) is a set of complex parameters defined through \(q^{\lambda} := y_i t^{-n}\). Note that \(\Lambda(y_i|p|q, t)\) is a power series in \(p\), \(\Lambda(y_i|0|q, t) = \sum_{i=0}^n y_i\).

**5 Quantum Dell Hamiltonians [15]**

A quantum counterpart of the Dell Hamiltonians proposed in [15] is
\[
\hat{\mathcal{D}}_a(w, u|q, t) := \hat{\mathcal{D}}_0^{-1}(w, u|q, t) \cdot \hat{\mathcal{D}}_a(w, u|q, t), \quad a = 1 \ldots n - 1
\] (44)
where \(\hat{\mathcal{D}}_a\) is read from
\[
\hat{\mathcal{D}}(z|w, u|q, t) = \sum_{k \in \mathbb{Z}} \hat{\mathcal{D}}_k(w, u|q, t) z^k := \sum_{k_1, \ldots, k_n \in \mathbb{Z}} z^{\sum_{i=1}^n k_i | w^\sum_{i=1}^n k_{i-1}/2} \prod_{i<j} \theta^{a^2} \left( t^{k_i-k_j} x_i / x_j \right) \prod_{i=1}^n \hat{T}_{q,x_i}^{k_i}
\] (45)
The Hamiltonians \( \hat{H}_n \) are conjectured to commute with each other (it was checked in \([15]\) for the first terms with the computer checks). The Hamiltonians depend on two parameters \( w \) and \( u \) that are associated with the double elliptic deformation. There is also a trivial Hamiltonian at \( a = n \):

\[
\hat{H}_n(w, p/q, t) = \prod_{i=1}^{n} T_{q, x_i}^{k_i}
\]

(46)

Shiraishi functions are trivially its eigenfunctions, since they are graded symmetric functions.

We conjecture that (an extension of) the Shiraishi master function \((35)-(36)\) solves the eigenvalue problem of the Dell Hamiltonians \((44)-(45)\):

\[
\hat{H}_n(w, u) \cdot x^\lambda \mathcal{P}_n \left( p^{n-i}x_i; p \middle| y_i; s \middle| q, \frac{q}{t} \right) = \Lambda(x, y_i; p, s \middle| q, t) \cdot x^\lambda \mathcal{P}_n \left( p^{n-i}x_i; p \middle| y_i; s \middle| q, \frac{q}{t} \right)
\]

(47)

with some identification of parameters \((w, u) \rightarrow (s, p)\). In particular, the limit \( s \rightarrow 1 \) corresponds to \( w \rightarrow 0 \). Note that \( \hat{H}_n(w, u) \) becomes functions at the \( q = t = 1 \) point, and these eigenvalues are dictated by the general rules of \([9]\). In fact, in the next section, we consider the case of \( n = 2 \) and demonstrate that the Shiraishi function provides an eigenfunction of the Dell Hamiltonian in the fundamental representation, while higher representations may require an extension.

Now we briefly consider various limits of this formula.

\( w \rightarrow 0 \) limit. In this limit, the Hamiltonians \((44)-(45)\) reduce to the elliptic Ruijsenaars Hamiltonians, in particular, the first one is \( \mathcal{D}_1 \) in \([8]\), and, in accordance with \([8]\), the Shiraishi function is an eigenfunction of this Hamiltonian provided the \( w \rightarrow 0 \) is associated with \( s \rightarrow 1 \). A typical exact formula is \([67]\).

\( u \rightarrow 0 \) limit. This limit is dual to the \( w \rightarrow 0 \) limit. Hence, one has to expect that it should correspond to the Shiraishi functions in the \( p \rightarrow 1 \) limit. On the other hand, the Dell Hamiltonians are reduced to this case in the Hamiltonians of the system dual to the elliptic Ruijsenaars one. Its eigenvalues can be explicitly constructed as we discuss in the next section in the two-particle case, the extension to arbitrary number of particles being immediate. As for the \( p \rightarrow 1 \) limit of the Shiraishi function, there are some problems with it.

\( p \rightarrow 1 \) limit. Indeed, the Shiraishi function is defined as a formal power series in \( p \). One may think that it is possible to use the duality \([38]\) in order to deal with this limit. However, as follows from \([38]\), the limit of \( \mathcal{P}_n(p^{n-i}x_i; p|y_i, y_2; s|q, \frac{q}{t}) \) at \( p \rightarrow 1 \) is given by

\[
\mathcal{P}_n(p^{n-i}x_i; p|y_i, y_2; s|q, \frac{q}{t}) \bigg|_{p \rightarrow 1} = \left( \frac{\mathcal{P}_n(p^{n-i}x_i; p|y_i, y_2; s|q, \frac{q}{t})}{\mathcal{P}_n(y_i, y_2; p|q^{n-i}x_i; s|q, \frac{q}{t})} \right) \mathcal{P}_n(y_i, y_2; p|q^{n-i}x_i; s|q, \frac{q}{t}) \bigg|_{p \rightarrow 1}
\]

(48)

Here the \( x \)-dependent factor \( \mathcal{P}_n(p^{n-i}x_i; p|y_i, y_2; s|q, \frac{q}{t}) \) is given by \([10]\) (note that, in accordance with \([10]\), \( \mathcal{P}_n(y_i, y_2; p|q^{n-i}x_i; s|q, \frac{q}{t}) \) does not depend on \( x_i \) and can be removed by changing the normalization) and requires a regularization in the \( p \rightarrow 1 \) limit:

\[
\mathcal{P}_n(p^{n-i}x_i; p|y_i, y_2; s|q, \frac{q}{t}) = \prod_{1 \leq i \leq n} (q x_j / x_i; q, p^n)_{\infty} \prod_{1 \leq i \leq j \leq n} (p^{n-2j + 2j} q x_j / x_i; q, p^n)_{\infty}
\]

(49)

is divergent at \( p \rightarrow 1 \). Hence, dealing with the Shiraishi function in the limit \( p \rightarrow 1 \) is not immediate.

\( p \rightarrow 0 \) limit. The limit \( p \rightarrow 0 \) in the Shiraishi functions is the limit to the ordinary Macdonald functions. We discuss it in detail in Appendix A. Note that, in this limit, the \( \theta \)-functions in \((44)-(45)\) become just

\[
\theta_p(x) \bigg|_{p \rightarrow 0} = \frac{1 - x}{\sqrt{x}}
\]

(50)

The Dell Hamiltonians \((45)\) have to reduce in this case to the ordinary Macdonald Hamiltonians, i.e. \( p \rightarrow 0 \) limit corresponds to both \( w \rightarrow 0 \) and \( u \rightarrow 0 \).

In the next section, we discuss our conjecture very explicitly in the case of \( n = 2 \).
6 Two particle $n = 2$ case

6.1 Shiraishi functions

Consider the simplest case of $n = 2$. In this case,

\[
\mathcal{P}_2(x_1, x_2; p | y_1, y_2; s | q, t) = \sum_{\lambda \vdash m \frac{1}{2}, \lambda' \vdash n \frac{1}{2}} \frac{N^{(0)}_{\lambda^0 \lambda^1}(t | q, s)}{N_{\lambda^0 \lambda^1}(1 | q, s)} \frac{N^{(0)}_{\lambda^0 \lambda^2}(t | q, s)}{N_{\lambda^0 \lambda^2}(1 | q, s)} \frac{N^{(1)}_{\lambda^1 \lambda^2}(ty_2/y_1 | q, s)}{N_{\lambda^1 \lambda^2}(1 | q, y_1/s)} \frac{N^{(1)}_{\lambda^1 \lambda^1}(ty_1/y_2 | q, s)}{N_{\lambda^1 \lambda^1}(1 | q, y_2/s)} \times (\frac{p}{t})^{\lambda^1 + \lambda^2} \left(\frac{x_2}{x_1}\right) \sum_{i \geq 1} (\lambda^1_{2i-1} - \lambda^1_{2i} + \lambda^2_{2i-1} - \lambda^2_{2i})
\]

(51)

Here

\[
N^{(0)}_{\lambda \mu}(u | q, s) := \prod_{j \geq 1 \text{ even}} \left( uq^{-\lambda_j + \lambda_{j+1}}s^{-j+1}; q \right)_{\lambda_j - \lambda_{j+1}} \prod_{j \geq 1 \text{ odd}} \left( uq^{\lambda_j - \lambda_{j+1}}s^{-j+1}; q \right)_{\lambda_j - \lambda_{j+1}}
\]

(52)

Note that potentially there could be factors that vanish at some values of $\lambda^{(1, 2)} \cdot N_{\lambda \lambda}(1 | q, s)$. However, the both factors that could restrict the admissible values of $\lambda^{(1, 2)}$, i.e. when the degree of $s$ is zero, have the form $(q^{-n}; q)_n$, which is non-vanishing. The sum (51) giving the Dell polynomial is a power series in $p$, which one can manifestly construct term by term. For instance, the constant term is just 1, and the linear term gets contributions when only one of $\lambda^{(1)}$ and $\lambda^{(2)}$ is non-vanishing and equal to 1. The first terms in $p$ in this expression are

\[
\mathcal{P}_2(x_1, x_2; p | y_1, y_2; s | q, t) = 1 + p \cdot \frac{1 - qt^{-1}}{1 - q} \left( \frac{qsy_1 - ty_2 x_1}{qsy_1 - y_2 x_2} + \frac{qsy_2 - ty_1 x_2}{qsy_2 - y_1 x_1} + \right)
\]

\[
+ p^2 \cdot \left( \frac{1 - qt^{-1}}{1 - q} \frac{q^2sy_1 - ty_2 qsy_1 - ty_2 x_1^2}{1 - q^2} - \frac{1 - qt^{-1}}{1 - q} \frac{q^2sy_1 - ty_2 qsy_1 - ty_2 x_1^2}{1 - q^2} + \frac{1 - qt^{-1}}{1 - q} \frac{q^2sy_2 - ty_1 qsy_2 - ty_1 x_2^2}{1 - q^2} - \frac{1 - qt^{-1}}{1 - q} \frac{q^2sy_2 - ty_1 qsy_2 - ty_1 x_2^2}{1 - q^2} + \text{const} \right) + O(p^3)
\]

Now, in accordance with (1), in order to make a reduction to the symmetric function corresponding to the Young diagram one has, first of all, to make the substitution $x_1 \to px_1$, $t \to \frac{q}{t}$:

\[
\mathcal{P}_2 \left( p \cdot x_1, x_2; p | y_1, y_2; s | q, \frac{q}{t} \right) = 1 + \sum_{k=0}^{\infty} \sum_{k=1}^{\infty} \frac{q^{k+1}}{1 - q^{k+1}} \frac{q^{k+1}}{1 - q^{k+1}} q^{k+1} sty_2 - y_1 x_2^2 + \ldots + O(p^2)
\]

(53)

Now one can restrict this function to particular Young diagram $R$. For instance, for $R = [1] = [1, 0]$ we put $y_1 = qts$, $y_2 = 1$ and the series in (53) is truncated so that only the first two terms survive, and one obtains

\[
\mathcal{M}_{[1]}^{(0)}(x_1, x_2 | p, s | q, t) = x_1 \cdot \mathcal{P}_2 \left( p \cdot x_1, x_2; p | qts, 1, s \right) \left( \frac{q}{t} \right) = x_1 + x_2 - O(p^2)
\]

(54)

Similarly, in the case of $R = [2] = [2, 0]$, one puts $y_1 = q^2ts$, $y_2 = 1$, the series (53) is truncated with only the three first terms remaining, and one obtains

\[
\mathcal{M}_{[2]}^{(0)}(x_1, x_2 | p, s | q, t) = x_1^2 \cdot \mathcal{P}_2 \left( p \cdot x_1, x_2; p | q^2ts, 1, s \right) \left( \frac{q}{t} \right) = x_1^2 + x_2^2 + \frac{(1 - t)(1 + q)}{1 - qt} x_1 x_2 + O(p^2)
\]

(55)

In the case of $R = [1, 1]$, one puts $y_1 = qts$, $y_2 = q$, only the first term in (53) remains, and one obtains

\[
\mathcal{M}_{[1, 1]}^{(0)}(x_1, x_2 | p, s | q, t) = x_1 x_2 \cdot \mathcal{P}_2 \left( p \cdot x_1, x_2; p | qts, q, s \right) \left( \frac{q}{t} \right) = x_1 x_2 + O(p^2)
\]

(56)

and so on.
Let us consider the fundamental representation $R = [1] = □$ in more detail. We collect more terms, the answer looks like

$$\mathfrak{M}^{(0)}_□(x_1, x_2|p, s|q, t) = x_1 \cdot \Phi_2 \left( p \cdot x_1, x_2; p \mid qts, 1; s \mid q, \frac{q}{t} \right) = (x_1 + x_2) \left[ 1 + p^2 \frac{1 - t}{1 - q^2s^2t} \left( \frac{q}{t} \frac{1 - q^2s^2t^2(1 + x_2)^2}{1 - q} + \frac{s^2 - q - t}{1 - s^2(2q + q + t + 2)} \right) \right] + O(p^4) \quad (57)$$

Note that one can also expand around the point $s = 1$. The function $\Phi_2 \left( p \cdot x_1, x_2; p \mid qts, 1; s \mid q, \frac{q}{t} \right)$ is singular at this point, and we explained in Sec. 4 how to choose the proper normalization factor in order to have a smooth limit: one has just to extract the constant term in the brackets in (57). Then, after rescaling, the answer has the form

$$\mathfrak{M}_□(x_1, x_2|p, s|q, t) = x_1 \cdot \xi \left( p \mid qts, 1; s \mid q, \frac{q}{t} \right)^{-1} \cdot \Phi \left( p \cdot x_1, x_2; p \mid qts, 1; s \mid q, \frac{q}{t} \right) = (x_1 + x_2) \left[ 1 + p^2 \frac{1 - t - q^2s^2t^2(x_1^2 - x_1x_2 + x_2^2)}{1 - q} \right] + O(p^4) \quad (58)$$

which, indeed, has a smooth limit at $s = 1$. Note that it can be written in the form

$$\mathfrak{M}_□(x_1, x_2|p, s|q, t) = p_0 + \eta_{001} \left( p^2 \frac{q}{t} \right) \cdot \left[ \eta_{120} \eta_{221} + p^2 \left( \eta_{120} \eta_{222} \eta_{221} \eta_{121}^{-1} \eta_{221}^{-1} - \frac{1 - q^2}{1 - q^2s^2t^2} \right) \right] : \Psi_1 + \eta_{001} \left( p^2 \frac{q}{t} \right)^2 \eta_{120} \eta_{222} \cdot \Phi_2 + O(p^6) \quad (59)$$

where the time variables are defined as $p_k := \sum_{i=1}^{2k+1} \frac{x_i}{t^i}$ and $\eta_{ijk} := \frac{1 - q^i s^j t^k}{1 - q^i s^j t^k} - \frac{1}{1 - q^i s^j t^k}$.

### 6.2 Shiraishi function in fundamental representation as an eigenfunction

Consider the Dell Hamiltonian in the two-particle, $n = 2$ case. In this case,

$$\hat{\mathfrak{H}}_0 = \sum_{k \in \mathbb{Z}} w_k^2 \theta_{a2} \left( t^{2k} \frac{x_1}{x_2} \right) \tilde{T}_{q,x_1} \tilde{T}_{q,x_2}, \quad \hat{\mathfrak{H}}_1 = \sum_{k \in \mathbb{Z}} w_k^2 \theta_{a2} \left( t^{2k-1} \frac{x_1}{x_2} \right) \tilde{T}_{q,x_1} \tilde{T}^{-k+1}_{q,x_2} \quad (60)$$

and one has to check that $\mathfrak{M}_R(x_1, x_2|p, w|q, t)$ solves the equation

$$\hat{\mathfrak{H}}_1(u, w|q, t) \mathfrak{M}_R(x_1, x_2|p, w|q, t) - \Lambda_R(p, w|q, t) \cdot \hat{\mathfrak{H}}_0(u, w|q, t) \mathfrak{M}_R(x_1, x_2|p, w|q, t) = 0 \quad (61)$$

with some eigenvalue $\Lambda_R(p, w|q, t)$. In the fundamental representation, it looks so that one can put $u = p$ so that the $p \to 0$ limit is equivalent to the $p \to 1$ limit (which could be the case if there exists a kind of modular invariance relating $p - 0$ and $p = 1$ points). We checked this with the computer, here we list just a few first terms of the $(w, p)$-expansion:

$$\Lambda_□(p, w|q, t) = -\frac{qt + 1}{t^{1/2}} + w \cdot \left( \frac{qt + 1}{t^{1/2}} \frac{(qt + 1)(q^2t^2 + 1)}{q^2t^2} - w^2 \left( \frac{(qt + 1)(q^4t^4 + q^3t^3 + q^2t^2 + qt + 1)}{q^2t^2} + \frac{(qt + 1)(q^2t^2 + 1)(q^4t^4 + q^3t^3 + q^2t^2 + qt + 1)}{q^2t^2} \right) \right) + O(w^4) \quad (62)$$

The parameters $s$ and $w$ are related in non-trivial way:

$$s - 1 = 2(qt^2 - 1)(qt^2 - 1)(qt^2 - 1) \left( \frac{w}{4q^2t^3} \right)^k \cdot \phi_k(q, t) \quad (63)$$

with

$$\phi_1(q, t) = qt + 1 \quad \phi_2(q, t) = 3q^2t^7 + 6q^6t^6 + q^4t^5 + q^3t^6 - 2q^5t^5 - 2q^4t^4 + 2q^3t^3 + 2q^2t^2 + qt^2 + qt^3 + qt^2 + 2qt + 1 \quad \phi_3(q, t) = 2(qt + 1)^2(5q^2t^2 + \ldots)$$
Note that the transformation gets a little bit simpler for the combination \( s^2 - 1 \):

\[
\frac{q t}{q^2 t^2 - 1} = \frac{(q t^2 - 1)(q^2 t^2 - 1)(q^2 t - 1)}{q t} \sum_{k=1}^{\infty} \left( \frac{w}{q^2 t^2} \right)^k \Phi_k(q, t)
\]

Then

\[
\Phi_1(q, t) = qt + 1
\]
\[
\Phi_2(q, t) = q^6 t^6 + 2q^7 t^5 - q^4 t^3 - q^3 t^4 - q^3 t^3 + q^2 t^2 + q^2 t + qt + q + t
\]
\[
\Phi_3(q, t) = (qt + 1)(q^{10} t^{10} + \ldots)
\]

... It looks like this relation between \( p \) and \( w \) does not depend on \( p \) and, hopefully, on the representation – hence, it is sufficient to calculate it in the first non-vanishing order in \( p \) for the fundamental representation. Thus, one can just substitute into (61) the first terms of expansion

\[
\theta_{-a}(z) = \frac{1 - z - p^2 z^{-1} + z^2 p^2}{\sqrt{z}} + O(p^4)
\]

and use only the terms written down in (58). In this way, one obtains a series of relations that are satisfied from the \( p^0 \)-terms and then

\[
\Lambda_{\square}(p, w|q, t) = \frac{1}{\sqrt{t}} \frac{\theta_{w}^{(c)}(qt/w)}{\theta_{w}^{(c)}(qt)} + O(p^2)
\]

from the \( p^0 \)-terms and then

\[
\Lambda_{\square}(p, w|q, t) = \frac{1}{\sqrt{t}} \frac{\theta_{w}^{(c)}(qt/w)}{\theta_{w}^{(c)}(qt)} + p^2 \cdot \frac{1}{\sqrt{t}(q - 1)\left(\theta_{w}^{(c)}(qt)\right)^2} \left[ \Xi_{q, t}^{(-1)} + \frac{\Xi_{q, t}^{(1)}\Xi_{q, t}^{(-1)}}{\Xi_{q, t}^{(1)}} \right] + O(p^4)
\]

\[
s^2 = \frac{1}{q t} \frac{\Xi_{q, t}^{(1)} - \Xi_{q, t}^{(-1)}}{\Xi_{q, t}^{(1)} - t\Xi_{q, t}^{(-1)}}
\]

\[
\Xi_{q, t}^{(a)}(w) := (q - 1) \left( t\theta_{w}^{(c)}(qt/w)\theta_{w}^{(c)}(t^3 q^a) - q^{(1-a)/2}\theta_{w}^{(c)}(qt)\theta_{w}^{(c)}(t^3 q^a/w) \right)
\]

from the \( p^2 \)-terms.

Thus, the relations that guarantee that (61) is correct in the fundamental representation and in the first two non-vanishing orders in \( p \) fix not only the first terms of \( p \)-expansion of the eigenvalues (60) but also the exact relation (67) between \( w \) and \( s \).

### 6.3 Dual to the elliptic Ruijsenaars system, \( u \to 0 \)

Formula (65) can be easily generalized to an arbitrary representation:

\[
\Lambda_{[r_1, r_2]}(p, w|q, t)_{p=0} = \frac{q^{r_2} \theta_{w}^{(c)}(q^{r_1 - r_2} t/w)}{\sqrt{t} \theta_{w}^{(c)}(q^{r_1 - r_2} t)} = \frac{y_2 \theta_{w}^{(c)}(y_1/w y_2)}{\sqrt{t} \theta_{w}^{(c)}(y_1/y_2)}
\]

where \( y_1 = q^{-r_1} t, y_2 = q^{r_2} \). This formula is consistent with (41), since, in accordance with the general rule (41), one has just to substitute in (15) \( T_{h, x_1} \), for \( y_i \) and remove the \( x \)-dependent factor.

Note that, say, in the case of the first symmetric representation \( R = [2] \), the eigenvalue is given by this formula, but the eigenfunction should be slightly corrected, i.e. the \( p \to 0 \) limit does not work in this case, and one has probably to consider \( p \to 1 \):

\[
\Psi_{[n]}(x_1, x_2|p, s|q, t) = M_{[n]}(x_1, x_2|q, t) - w x_1 x_2 \cdot \frac{q}{t^2} \frac{(y_1 - t y_2)(y_1 - q t y_2)}{y_1 - q y_2} \frac{(t - 1)(q - t)}{q - 1} \frac{y_1 + y_2}{y_1} M_{[n-2]}(x_1, x_2|q, t) + O(w^2) + O(p^2)
\]
These expressions should be compared with

$$\Psi_{[1]}(x_1, x_2|p, s|q, t) = M_{[1]}(x_1, x_2|q, t) + O(p^2)$$  \hspace{1cm} (71)$$

since there is no \(x_1x_2\) term by grading. This explains why, for the fundamental representation, the Shiraiishi function is an eigenfunction even at \(p = 0\): in all these cases, the answer is just the ordinary fundamental Macdonald polynomial.

The general eigenfunction can be realized as a finite sum

$$\Psi_{[n]}(x_1, x_2|0, s|q, t) = \sum_{k=0}^{n} \beta_k(y_1, y_2 |w|q, t) M_{[n-2k]}(x_1, x_2|q, t^k) (x_1 x_2)^k$$  \hspace{1cm} (72)$$

with the coefficients \(\beta_k(y_1, y_2 |w|q, t) \sim w^k + O(w^{k+1})\). For \(y_1 = q^t, y_2 = 1\) they look like

$$\beta_k(y_1, y_2 |w|q, t) = \sum_{i=0}^{k} \alpha_i(k) \cdot \left( \frac{q^i - 1}{q^i} \right) \cdot \prod_{j=1}^{k-i} \frac{q^{2j} - 1}{q^j - 1} \cdot \frac{q^{k-j} - 1}{q^j - 1}$$  \hspace{1cm} (73)$$

where we have introduced the \(\theta\)-function of genus 2:

$$\Theta(w|z_1, z_2) := \frac{w^{1/4}}{z_{12}^{1/2}} \left( \theta_{w}^{(c)}(z_1) \theta_{w}^{(c)}(\frac{z_2}{w}) - \sqrt{\frac{z_2}{z_1}} \cdot \theta_{w}^{(c)}(z_2) \theta_{w}^{(c)}(\frac{z_1}{w}) \right)$$  \hspace{1cm} (74)$$

In the notation of [1], the genus 2 \(\theta\)-function defined in formula (53) of [1] is associated with this one upon the identification

\[ s = 0, \quad w = e^{2\pi ir}, \quad z_1 = e^{2\pi i(\xi_1 + \xi_2)}, \quad z_2 = e^{2\pi i(\xi_1 - \xi_2)} \]

Now, using formula (72), one can lift these formulas up to the mother function:

$$\Psi(x_1, x_2|y_1, y_2 |w|q, t) = \sum_{k, n=0}^{\infty} \beta_k(y_1, y_2 |w|q, t) M_{[n-2k]}(x_1, x_2|q, t^k) (x_1 x_2)^k$$  \hspace{1cm} (75)$$

such that

$$\mathcal{D}_0^{-1} \mathcal{D}_1 \bigg|_{p=0} \cdot x^\lambda \Psi(x_1, x_2|y_1, y_2, w|q, t) = \frac{y_2}{\sqrt{\theta_{w}^{(c)}(y_1/y_2)} \theta_{w}^{(c)}(y_1/w_2)} \cdot x^\lambda \Psi(x_1, x_2|y_1, y_2, w|q, t)$$  \hspace{1cm} (76)$$

which solves the eigenfunction problem for the \(n = 2\) dual Ruijsenaars Hamiltonian. These formulas can be straightforwardly generalized to \(n > 2\).

### 6.4 A way to construct the eigenfunctions

Let us explain one of the ways to construct the eigenfunctions of the Dell Hamiltonian in the two-particle case that gives the answer immediately in terms of the genus two \(\theta\)-functions. It also avoids re-expansion in terms of Macdonald polynomials, which was attempted in (70).

Expanding Hamiltonian (70) in powers of \(w\) and \(u\),

$$\mathcal{D}_0 = \sum_{k,l \geq 0} w^{k^2} u^{l(l-1)} \mathcal{D}_0^{(k,l)}, \quad \mathcal{D}_1 = \sum_{k,l \geq 1} w^{k(k-1)} u^{l(l-1)} \mathcal{D}_1^{(k,l)}$$  \hspace{1cm} (77)$$

one obtains very simple and instructive recurrent formulas for their action on arbitrary symmetric functions of two \(x\)-variables:

$$\frac{\sqrt{x_1x_2}}{x_1 - x_2} \cdot \mathcal{D}_0^{(k,l)} \left( \frac{x_1^{r+1} - x_2^{r+1}}{x_1 - x_2} \cdot (x_1x_2)^m \right) =$$

$$= \frac{(-1)^{l-1}}{1 + \delta_{k,0}} \cdot \text{sym} \left( q^r t^k (2l-1) \right) \cdot \frac{x_1^{r+1} - x_2^{r+1}}{x_1 - x_2} \cdot \frac{x_1^{2l-1} - x_2^{2l-1}}{x_1 - x_2} \cdot (x_1x_2)^{m+1-l}$$
where \( \text{sym}(x) = x + \tfrac{1}{2} \) and \( \text{asym}(x) = x - \tfrac{1}{2} \). This is true for all integer \( r, k, l \geq 0 \) and for all integer \( m \), not obligatory positive. Thus, one gets a general description of bi-triangular action in the case of two \( x \)-variables, which is easy to sum over \( k \) and \( l \) and express the answer in terms of genus two \( \theta \)-functions. For \( m \geq 0 \), the l.h.s. can be considered as action of \( \mathcal{D} \)-operators on an arbitrary two-line Schur function \( \text{Schur}_{r+m,m}[x_1, x_2] = \sum_{j=1}^{r} \frac{x_1^{r+1-j} - x_2^{r+1-j}}{x_1 - x_2} \cdot (x_1 x_2)^{m+j-1} \), which can be straightforwardly generalized from two to an arbitrary number of \( x \)-variables. The Hamiltonians are the ratios of these triangular matrices, but most interesting properties should be seen already at the level of (78). The \( x \leftrightarrow y \) symmetry is not yet explicit and should be revealed at further stages.

7 Conclusion

To summarize, in this paper, we discussed the appealing possibility that the self-dual Shiraishi series provide eigenfunctions of the Dell systems. We modelled the latter by the version recently advocated by P. Koroteev and Sh. Shakirov based on the old suggestion to use higher genus theta-functions with a constant period matrix. Conjecturally, the dynamical period matrix, reflecting the Seiberg-Witten symplectic structure can arise after projection from genus \( n \) to \( n-1 \), which is a standard step in the study of the Calogero-Ruijsenaars family systems, but this remains to be explicitly worked out. Anyhow, the Hamiltonians (44) have a nice triangular structure, which allows a straightforward construction of eigenfunctions through peculiar recurrent relations. This seems indeed consistent with J. Shiraishi’s anzatz, though some details remain to be clarified. In two Appendices below, we further comment on the relation of the entire construction to network DIM-based models, which are widely used to build Nekrasov functions from Dotsenko-Fateev integrals. Once again, some effort is still needed to “close the circle” and fully reveal the symplectic structures and rich symmetries of the theory in the Dell case. Hamiltonians and their eigenfunctions arise from Nekrasov functions in the \( \epsilon_2 = 0 \) (Nekrasov-Shatashvili) limit, but the Shiraishi functions can appear applicable even beyond it. In the forthcoming paper [32], we discuss an improved version of our claim, with an additional elliptic deformation of the Shiraishi series.

Acknowledgements

We would like to thank M. Fukuda for discussion, in particular for telling us the results prior to the submission to arXiv. We are grateful to P. Koroteev, Sh. Shakirov, G. Aminov and Y. Zenkevich for enthusiasm and useful discussions and to A. Smirnov, who also consulted us on the modern terminology in the field.

Appendix A. $p \to 0$ limit of the Shiraishi function and $T[U(n)]$ theory

In the limit of $p \to 0$, the Shiraishi function reduces to

$$
\lim_{p \to 0} \Psi_n(p^{n-i}x; p^s y; s|q, t) = \sum_{\chi} \prod_{i,j=1}^{n} \left( \frac{\chi^i_j}{y_i^s} \right)^n \prod_{\beta=1}^{n-\beta} \left( \frac{t x_{a+\beta}^a}{q x_{a+\beta-1}^a} \right)^{\lambda^{(a)}_{(\beta)}}
$$

(79)

where we have made a change of parameter $t$ to $\frac{q}{t}$ for the consistency with the function $P_n(x|y|q,t)$ defined by (1). Note that we made the scaling $p^\beta x = (p^{n-i}x_1, \ldots, p x_{n-1}, x_n)$ and similarly for the dual variables $(y_1, s)$, which gives an additional factor $s^{-i-j}$. Due the scaling of $x$ variables, the power $p x_{a+\beta}/t x_{a+\beta-1}$ appearing in $\Psi_n(x; p|y; s|q,t)$ is scaled to $(p^n x_{a+\beta}/t x_{a+\beta-1})^{\lambda^{(a)}_{(\beta)}}$, if $\alpha + \beta \equiv 1 \mod n$ and $(x_{a+\beta}/t x_{a+\beta-1})^{\lambda^{(a)}_{(\beta)}}$ otherwise. Hence to obtain a non-vanishing result in the limit $p \to 0$ we have to impose $\lambda^{(a)}_{(\beta)} = 0$ for $\alpha + \beta = n + 1$. Thus the length of the partition $\lambda^{(a)}_{(\beta)}$ is at most $n - \beta$, which is the restriction on $\alpha$ in (79). As we will see later by examining the selection rule in (36), the right hand side of (79) is actually independent of the dual elliptic parameter $s$. In [23], it is pointed out that the Shiraishi function in the limit of $p \to 0$ agrees with the function $P_n(x|y|q,t)$ introduced in [31] as a solution to the bispectral problem for the Ruijsenaars-Macdonald $q$-difference operators.

As we demonstrate in Appendix B, $\Psi_n(x; p|y; s|q,t)$ is identified with the Nekrasov partition function of $N = 2^*$ $SU(n)$ gauge theory with the maximal monodromy defect which breaks $SU(n)$ completely to $U(1)^{n-1}$. In the four dimensional case, the surface defect has another description by $N = 2\times (2,2)$ gauged linear sigma model coupled to the bulk theory [33]. The coupling is achieved by gauging the flavor symmetry and the (twisted) mass parameters are identified with the Coulomb moduli of the bulk theory. When the bulk theory is five dimensional, we should consider $S^1$ lift of the two dimensional $N = (2,2)$ theory. In the limit of $p \to 0$, only the “perturbative” sector (the zero instanton number sector) survives. From the viewpoint of 3d theory on the codimension two defect, this means the bulk contribution decouples. Hence, we expect that the function $\Psi_n(x; p|y; s|q,t)$ in the limit of $p \to 0$ is identified with the vortex partition function of 3d theory. In the following we show this is indeed the case. Namely, the function $P_n(x|y|q,t)$ agrees with the vortex counting partition function for the holomorphic block of 3d $\mathcal{N} = 4$ $T[U(n)]$ theory, where the identification of the parameters are:

$$
\begin{array}{c|c}
P_n(x|y|q,t) & 3d \mathcal{T}[U(n)] \text{ theory} \\
\hline
x & \text{FI parameters} \\
y & \text{real mass parameters} \\
t & \text{axial (adjoint) mass} \\
q & 2d \Omega \text{ background} \\
\end{array}
$$

Note that $T[U(n)]$ theory is self-mirror where the 3-dimensional mirror symmetry exchanges the FI parameters and the chiral mass parameters. This is consistent with the fact that $P_n(x|y|q,t)$ is a solution to the bispectral problem [31].

$T[U(n)]$ theory is a 3 dimensional $\mathcal{N} = 4$ quiver gauge theory with gauge group $U(1) \times U(2) \times \cdots \times U(n-1)$. Originally it was introduced as a boundary theory of 4 dimensional $\mathcal{N} = 4$ supersymmetric Yang-Mills theory [34]. The theory has bifundamental matters connecting the adjacent nodes and $n$ hypermultiplets at the final node. Thus the flavor symmetry is $U(n)$. In [35] the vortex counting partition function for the holomorphic block of 3D $\mathcal{N} = 4$ $T[U(n)]$ theory is computed as follows (see also [36], [37]):

$$
Z_{\text{vortex}}(\bar{\mu}, \bar{\tau} | q, t) = \sum_{\{k_i^{(a)}\}} \prod_{a=1}^{n-1} \frac{q^{T_{a}^a}}{T_{a}^{a+1}} \prod_{i \neq j}^{a} \frac{(\mu_i^a q_{ij}^{(a)\ast} q_{ij}^{(a)\ast})^{-1}}{\mu_i^a q_{ij}^{(a)\ast}} \prod_{i=1}^{a} \prod_{j=1}^{a+1} \frac{(\mu_i^a q_{ij}^{(a)}}{\mu_i^{a+1}} \frac{(\mu_i^a q_{ij}^{(a)})^{-1}}{\mu_i^{a+1}},
$$

(80)

where we have replaced $t$ in the original formula with $\frac{q}{t}$, which is related to the Poincaré duality of $P_n(x|y|q,t)$ [31]. The parameters $\bar{\tau}$ and $\bar{\mu}$ are the (exponentiated) FI and mass parameters, respectively. Under the 3-dimensional mirror symmetry which exchanges the Coulomb branch and the Higgs branch, we have [35]:

$$
\bar{\tau} \leftrightarrow \bar{\mu}, \quad t \leftrightarrow \frac{q}{t}.
$$

(81)

The set of non-negative integers $k_i^{(a)}$ ($1 \leq i \leq a$) comes from the positions of poles in the contour integral of
screening currents and satisfies the condition:

\[ k_1^{(1)} \geq k_1^{(2)} \geq k_1^{(3)} \geq \ldots \geq k_1^{(n-1)}, \]
\[ k_2^{(2)} \geq k_2^{(3)} \geq \ldots \geq k_2^{(n-1)}, \]
\[ \ldots \]
\[ k_{n-2}^{(n-2)} \geq k_{n-1}^{(n-1)}, \]
\[ k_{n-1}^{(n-1)} \]

(82)

The upper label \( a \) of the integers \( k_i^{(a)} \) stands for the color (or the \( \mathbb{Z}_n \) orbifold charge) from the defect and each row of the inequalities above corresponds to the Young diagram \( \lambda(i) \) with height \( \ell(\lambda(i)) = n - i \). Note that the genuine holomorphic block has also classical and one-loop contributions [35]:

\[ B_{T^{2\times S^1}}^{\mathbb{R}^2 \times S^1} = Z_{\text{cl}} \left( \vec{\mu}, \vec{\tau} \bigg| q, \frac{q}{t} \right) Z_{1\text{-loop}} \left( \vec{\mu}, \vec{\tau} \bigg| q, \frac{q}{t} \right) Z_{\text{vor}} \left( \vec{\mu}, \vec{\tau} \bigg| q, \frac{q}{t} \right), \]

where

\[ Z_{1\text{-loop}} \left( \vec{\mu}, \vec{\tau} \bigg| q, \frac{q}{t} \right) = \prod_{1 < j} \frac{(q\mu_j; q)_\infty}{(t\mu_j; q)_\infty}, \]

(84)

The classical part contains the theta function

\[ Z_{\text{cl}} \left( \vec{\mu}, \vec{\tau} \bigg| q, \frac{q}{t} \right) \sim \prod_{1 < j} \frac{\theta_q \left( \frac{q\mu_j}{t\mu_i} \right)}{\theta_q \left( \frac{\mu_i}{\mu_j} \right)}. \]

(85)

which implies some cancellations of \( q \)-shifted factorials between \( Z_{1\text{-loop}} \) and \( Z_{\text{cl}} \). The perturbative contribution \( Z_{\text{cl}} \cdot Z_{1\text{-loop}} \) corresponds to the normalization factor of the function \( [n] \), which is invertible for the bispectral duality [31]. It is quite remarkable that the vortex counting function \( Z_{\text{vor}}(\vec{\mu}, \vec{\tau}|q,t) \) is obtained from the “Higgsed” network model of \( \text{DIM} \) (quantum toroidal) algebra \( U_{\hat{q}}(\hat{\mathfrak{g}}_1) \) [38]. See also the computation in Appendix A of [39]. Hence it is natural to expect the Shiraishi function \( \Psi_n(x; p| y; s|q,t) \) for \( p \neq 0 \) can be obtained by compactifying the “Higgsed” network [40]. We can associate the elliptic modulus \( p \) with the compactified edge, while the appearance of the dual elliptic parameter \( s \) seems rather tricky.

We can check that \( P_n(x|s|q,t) \) agrees with \( Z_{\text{vor}}(\vec{\mu}, \vec{\tau}|q, \frac{q}{t}) \) with the relation

\[ \theta_{ij} = \lambda_{j-i}^{(i)} = \lambda_{j-i+1}^{(i)} - k_i^{(j)} \]

Substituting this relation, we obtain

\[ C_n(k_i^{(a)}; y|q,t) = \prod_{1 \leq i < j \leq a+1} \frac{(q^{k_i^{(a)}-k_j^{(a+1)}}, \frac{q\mu_i}{y}; q)_{k_i^{(a)}-k_j^{(a+1)}}}{(q^{k_j^{(a+1)}-k_i^{(a)}}, \frac{q\mu_j}{y}; q)_{k_j^{(a+1)}-k_i^{(a)}}} \prod_{1 \leq i < j \leq a} \frac{(q^{k_j^{(a)}-k_i^{(a+1)}}, \frac{q\mu_j}{y}; q)_{k_j^{(a+1)}-k_i^{(a+1)}}}{(q^{k_i^{(a+1)}-k_j^{(a)}}, \frac{q\mu_i}{y}; q)_{k_i^{(a+1)}-k_j^{(a+1)}}}, \]

(87)

where we have set \( a = k - 1 \). We see that the factors in \( C_n \), with \( 1 \leq i < j \leq a \) are

\[ \frac{(q^{-\theta_{ik}}; q\mu_i)}{(q^{-\theta_{jk}}; q\mu_j)} = \left( \frac{q}{t} \right)^{k_i^{(a)} - k_j^{(a+1)}} \frac{(t; q)_{k_i^{(a)}-k_j^{(a+1)}}}{(q; q)_{k_i^{(a)}-k_j^{(a+1)}}}, \]

(88)

We find up to the power of \( q \), the corresponding factors in \( Z_{\text{vor}} \) are exactly the same as above. When \( i < j \), we use the formula

\[ (q^n u; q)_n = (u; q)_{m+n} \]

(89)

which is valid also for negative integers. Then we find the following factors:

\[ \frac{(q\nu_i; q)_{k_i^{(a)}-k_j^{(a+1)}}}{(q\nu_j; q)_{k_j^{(a+1)}-k_i^{(a+1)}}}, \]

\[ \frac{(t\nu_i; q)_{k_i^{(a+1)}-k_j^{(a+1)}}}{(t\nu_j; q)_{k_j^{(a+1)}-k_i^{(a+1)}}}, \]

(90)
and
\[
\begin{align*}
\frac{(q y_i; q)_{k_i^{(a)}-k_i^{(a)\alpha}}}{(q y_i; q)_{k_i^{(a+1)}-k_i^{(a)\alpha}}} 
\frac{(q y_i; q)_{k_i^{(a)}-k_i^{(a)\alpha}}}{(q y_i; q)_{k_i^{(a+1)}-k_i^{(a)\alpha}}} = 1 \leq i < j \leq a
\end{align*}
\]
(91)

In each case we see the first factor agrees with the factors in \(Z \text{ vor} \) with \( i < j \) by substituting \( y_i = \mu_i^{-1} \), where we have taken the condition \( k_i^{(n)} = 0 \) into account. To obtain the missing factors with \( j < i \), we exchange \( i \) and \( j \) in the second factors of (36) and there is a unique solution
\[
≤ k \leq j
\]
respectively. Taking the condition \( k_i^{(n)} = 0 \) into account again, we can see these factors indeed give the missing factors for \( j < i \) in \( Z \text{ vor} \), up to the power of \( \frac{q}{t} \). Finally for completeness let us count the total power of \( \frac{q}{t} \) that arose during the above computations:
\[
\sum_{a=1}^{n-1} \sum_{i=1}^{a} (k_i^{(a)} - k_i^{(a+1)}) + \sum_{a=1}^{n-1} \sum_{1 \leq j < i \leq a+1} (k_i^{(a+1)} - k_i^{(a)}) + \sum_{a=1}^{n-1} \sum_{1 \leq j < i \leq a} (k_i^{(a)} - k_i^{(a+1)})
\]
\[
= \sum_{a=1}^{n-1} \sum_{i=1}^{a} k_i^{(a)} - \sum_{a=1}^{n-1} \sum_{j=1}^{a} k_j^{(a+1)} - \sum_{a=1}^{n-2} \sum_{1 \leq j < i < a+1} k_i^{(a+1)} - \sum_{a=1}^{n-1} \sum_{1 \leq j < i \leq a} k_i^{(a)}
\]
\[
= \sum_{a=1}^{n-1} \sum_{i=1}^{a} k_i^{(a)}
\]
(95)

where we have used \( k_i^{(n)} = 0 \). Hence the power is exactly the same as that of (79).

Armed with the agreement of the Noumi-Shiraishi representation of the Macdonald function \( P_n(x|y|q,t) \) and the vortex partition function of \( T[U(n)] \) theory, we can show that they also agree with (79). We first have to examine the selection rule in the Nekrasov factor (50). Since \( 1 \leq a \leq \beta \leq n-1 \) in the limit \( p \to 0 \), when \( k \geq 0 \), there is no solution to the selection rule in the second factor of (36) and there is a unique solution \( \beta = \alpha + k \) to the selection rule in the first factor. On the other hand when \( k < 0 \), it is the second factor that has a unique solution \( \beta = \alpha - k - 1 \) and the first factor has no solution to the selection rule. Hence, substituting the relation \( \lambda_{t}^{(i)} = k_i^{(i+1)} \) we obtain the following three contributions:

1. \( i = j \)
\[
\prod_{i=1}^{n} \frac{N_{\Lambda^{(0)}(\lambda^{(i)},\lambda^{(i)})}(q,t; s)}{N_{\Lambda^{(0)}(\lambda^{(i)},\lambda^{(i)})}(1; q; s)} = \prod_{i=1}^{n-1} \prod_{a=1}^{n-i} \frac{(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}}{(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}}
\]
(96)

2. \( i < j \)
\[
\prod_{1 \leq i < j \leq n} \frac{N_{\Lambda^{(j-1)}(\lambda^{(i)},\lambda^{(i)})}(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}}{(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}}
\]
\[
= \prod_{1 \leq i < j \leq n} \prod_{a=1}^{n-j} \frac{(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}}{(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}(q\, q)_{k_i^{(i+1)-k_i^{(i+1)}}}}
\]
(97)
3. \( i > j \)

\[
\prod_{1 \leq j < i \leq n} \frac{N^{(j-i)}_{\lambda(i), \lambda(i)} \left( s^{i-j} \frac{q_y}{t_x} \mid q, s \right)}{N^{(j-i)}_{\lambda(i), \lambda(i)} \left( s^{i-j} \frac{q_y}{t_x} \mid q, s \right)} = \prod_{1 \leq j < i \leq n} \prod_{\alpha=1}^{n-i+1} \left( \frac{q^{(y_j)}; q}{q^{(y_j)}; q} k^{(s-a)}_{i-a} - k^{(s-a+1)}_{i-a} \right) \frac{q^{(y_i)}; q}{q^{(y_i)}; q} k^{(s-a)}_{i-a} - k^{(s-a+1)}_{i-a}
\]

(98)

In the first case, setting \( a = i + \alpha - 1 \), we have \( 1 \leq a \leq n - 1 \) and \( 1 \leq i \leq a \). Hence the contribution becomes

\[
\prod_{a=1}^{n-i} \prod_{1 \leq j < i \leq n} \left( \frac{q^{(y_j)}; q}{q^{(y_j)}; q} k^{(s-a)}_{i-a} - k^{(s-a+1)}_{i-a} \right) \frac{q^{(y_i)}; q}{q^{(y_i)}; q} k^{(s-a)}_{i-a} - k^{(s-a+1)}_{i-a}
\]

(99)

In the second case, setting \( a = j + \alpha - 1 \) implies \( 2 \leq a \leq n - 1 \) and \( 1 \leq i < j \leq a \). Hence we obtain

\[
\prod_{a=2}^{n-i} \prod_{1 \leq j < i \leq a} \left( \frac{q^{(y_j)}; q}{q^{(y_j)}; q} k^{(s-a)}_{i-a} - k^{(s-a+1)}_{i-a} \right) \frac{q^{(y_j)}; q}{q^{(y_j)}; q} k^{(s-a)}_{i-a} - k^{(s-a+1)}_{i-a}
\]

(100)

where we have used (92). Finally in the last case, setting \( a = i + \alpha - 2 \) implies \( 1 \leq a \leq n - 1 \) and \( 1 \leq j < i + 1 \)

\[
\prod_{a=1}^{n-i-1} \prod_{1 \leq j < i \leq a+1} \left( \frac{q^{(y_j)}; q}{q^{(y_j)}; q} k^{(s-a)}_{i-a} - k^{(s-a+1)}_{i-a} \right) \frac{q^{(y_j)}; q}{q^{(y_j)}; q} k^{(s-a)}_{i-a} - k^{(s-a+1)}_{i-a}
\]

(101)

where we have used (92) again. Then by the same change of variables \( y_i = 1/\mu_i \) as before we can find an agreement with (80) up to the power of \( q \). Note that we have to exchange \( i \) and \( j \) for the factors with \( k^{(s-a)}_{i-a} - k^{(s-a+1)}_{i-a} \). Finally one can check the total power of \( q \) is correct by a similar counting to (95).

Appendix B. Shiraishi function and maximal monodromy defect

Let us note that the power of the series expansion (55) can also be rewritten as

\[
\prod_{\beta=1}^{n} \prod_{\alpha \geq 1} \left( \frac{q^{(x_{\beta+i})}; q}{q^{(x_{\beta+i})}; q} t^{x_{\beta+i+1}} \right)^{\lambda^{(\beta)}} = \left( \frac{q}{t} \right)^{\sum_{\beta=1}^{n} x_{\beta}},
\]

(102)

where \( m_i = d_i - d_{i+1} \) with

\[
|\vec{\lambda}| := \sum_{\beta=1}^{n} |\lambda^{(\beta)}|, \quad d_i(\vec{\lambda}) := \sum_{\alpha=1}^{\infty} \sum_{\beta+i \equiv \alpha \pmod{n}} \lambda^{(\beta)}
\]

(103)

The integer \( m_i \) with \( \sum_{i=1}^{n} m_i = 0 \) corresponds to the magnetic flux associated with the monodromy defect which breaks \( SU(n) \) to \( U(1)^{n-1} \). In (23) it was pointed out \( \Psi_n(x_i; p|y_i; s|q, t) \) is identified with the equivariant Euler characteristic of the affine Laumon space (22), while in (15) it was argued that the eigenfunction of elliptic integrable system is related to the instanton partition function with monodromy defect, which in turn is obtained from the ordinary instanton partition function by introducing appropriate \( \mathbb{Z}_n \)-orbifold action on the equivariant parameters (12), (22), (21), (23), (37), (46).

In the following we summarize how the orbifold action correctly reproduces the equivariant Euler characteristic of the affine Laumon space derived in (22). In fact, at the level of the equivariant character to be discussed later, the selection rules \( j - i \equiv k \pmod{n} \) and \( \beta - \alpha \equiv -k - 1 \pmod{n} \) mean taking the terms with the charge \( k/n \), if we assign the fractional charge \( 1/n \) for the orbifold action of \( \mathbb{Z}_n \) to the parameter \( s \). Hence if we define the charge of the Coulomb moduli parameter \( y_i \) to be \( -i/n \), then the function \( \Psi_n(x_i; p|y_i; s|q, t) \) corresponds to the neutral (integral) charge sector of the equivariant character.

Let us first confirm the Nekrasov factor (33) without the selection rules

\[
N_{\lambda, \mu}(u|q, 1/s) = \prod_{j \geq 1} \left( u q^{-\mu_i + \lambda_{j-1}} s^{-j} q \right) \lambda_j - \lambda_{j+1} \cdot \prod_{\beta \geq 0} \left( u q^{|\lambda_0 - \mu_\beta | s^\beta - \alpha + 1} q \right)_{\mu_\beta - \mu_{\beta+1}},
\]

(104)
agrees with the standard one (see e.g. [47]). Using [50], we obtain
\[ N_{\lambda,\mu}(uq,1/s) = \prod_{j \geq i \geq 1} \frac{(uq^{\lambda_j+1}-\mu_is^{1+j};q)_{\infty}}{(uq^{\lambda_j+1}-\mu_is^{1+j};q)_{\infty}} \cdot \prod_{i \geq j \geq 1} \frac{(uq^{\lambda_j}-\mu_is^{1+j+1};q)_{\infty}}{(uq^{\lambda_j}-\mu_is^{1+j};q)_{\infty}} = \]
\[ = \prod_{i,j=1}^{\infty} \frac{(uq^{\lambda_i-\mu_is^{1+j+1}};q)_{\infty}}{(uq^{\lambda_i-\mu_is^{1+j}};q)_{\infty}} \cdot \frac{(us^{1-j};q)_{\infty}}{(us^{1-j+1};q)_{\infty}} = \]
\[ = \exp \left( \sum_{n=1}^{\infty} \frac{u^n}{n} - s^n \left[ p_n(q^{\lambda} s^{-j}) p_n(q^{-\mu} s^l) - p_n(s^{-j}) p_n(s^l) \right] \right) \quad (105) \]
where \( p_n(\bullet) \) is the power sum function. Thus we can see \( N_{\lambda,\mu}(uq,1/s) \) agrees with the standard Nekrasov factor in terms of the power sum functions. We note that the equivariant parameters for the \( \Omega \) background is \( q_1 = e^s = q \) and \( q_2 = e^{2s} = s^{-1} \) and \( t \) does not correspond to the \( \Omega \) background: physical meaning of the parameter \( t \) is the mass of the adjoint matter \( t = e^{-m} \). On the other hand when we drive the Macdonald function from \( \mathfrak{P}_n(x; p|y_i; s|q, t) \) the deformation parameters are actually \( (q, t) \). Thus there is “a mismatch” between the deformation parameters of the Macdonald function and the \( \Omega \) background.

Geometrically the Nekrasov factor \( N_{\lambda,\mu}(uq,s) \) is derived from the equivariant character of the tangent space of the instanton moduli space \( T^*_U M \) at the isolated fixed points of the torus action, which are labelled by \( n \)-tuples of Young diagrams \( \lambda = \{ \lambda^a \} \). According to [48], [49], the relevant equivariant character is given by:
\[ \chi(u_\alpha; q_1) = N^* K + q_1 q_2 K^* N - (1 - q_1)(1 - q_2) K^* K, \quad (106) \]
where
\[ N := \sum_{\alpha=1}^{n} u_\alpha, \quad K := \sum_{\alpha=1}^{n} u_\alpha \cdot \left( \sum_{(i,j) \in \lambda^a} q_1^{i-j} q_2^{-i} \right) \quad (107) \]
\( N^* \) and \( K^* \) denote dual characters. \( u_\alpha \) are coordinates of the Cartan torus of the gauge group \( U(n) \) and \( q_1 \) is equivariant parameters of the torus action on \( C^2 \).

The equivariant character of the tangent space at the fixed points of the affine Laumon space is given by \( Z_n \) invariant part of the character by introducing the orbifold action on the equivariant parameters \( (u_\alpha,q_1) \). Thus the denominator of the Shiraishi function \( \mathfrak{P}_n(x; p|y_i; s|q, t) \) is related to the equivariant character of the affine Laumon space [23], which is identified with the instanton moduli space with the maximal monodromy defect corresponding to the partition \( N = (1^n) \), which breaks \( U(n) \) completely to \( U(1)^n \). The CFT side of the AGT relation in this case is supposed to be the conformal block of the affine algebra \( sl_n \) [50], [51].

Let us show \( Z_n \) invariant part of the equivariant character (106) actually gives the character formula [42]
\[ Ch(\check{\lambda},\check{\mu})(a, b; q_1, q_2) = \]
\[ = (1 - q_1) \sum_{k=1}^{n} \sum_{1 \leq \ell \leq k} \prod_{i=1}^{(k-\ell)} \sum_{j=1}^{q_1^{i-j} q_2^{i-j}} \chi^{(k-\ell)} \]
\[ + q_1 \sum_{k=1}^{n} \sum_{1 \leq \ell \leq k} e^{a_k-b_k-i} q_2^{-i} \sum_{j=1}^{q_1^{i-j} q_2^{i-j}} \chi^{(k-\ell+1)} \]
\[ - (1 - q_1) \sum_{k=1}^{n} \sum_{1 \leq \ell \leq k} \prod_{i=1}^{(k-\ell+1)} \sum_{j=1}^{q_1^{i-j} q_2^{i-j}} \chi^{(k-\ell+1)} \]
\[ + \sum_{k=1}^{n} \sum_{1 \leq \ell \leq k} e^{a_k-b_k-i} q_2^{-i} \sum_{j=1}^{q_1^{i-j} q_2^{i-j}} \chi^{(k-\ell)} \quad (108) \]
where we have made a change of variables \( \ell \rightarrow k - \ell + 1 \) and \( \tilde{\ell} \rightarrow k - \tilde{\ell} + 1 \) (but \( \tilde{\ell} \rightarrow k - \tilde{\ell} + 1 \) only for the third term) in the original formula (Prop. 4.15 in [42]). Multiplied with \( e^{-m} \), (110) gives the character for a bifundamental matter with mass \( m \). To get an adjoint matter we specialize \( a = b \) and \( \lambda = \mu \). The character for the vector multiplet is obtained from that of adjoint matter by setting \( m = 0 \) and reversing the overall sign.

---

1. Compared with the standard formula, we have exchanged \( q_1 \) and \( q_2 \), or take the transpose of the Young diagram.
Replacing $\ell \to m n + \ell$ and $\tilde{\ell} \to \tilde{m} n + \tilde{\ell}$ with $0 \leq m, \tilde{m}$ and $1 \leq \ell, \tilde{\ell} \leq n$, we can rewrite the character as follows:

$$
\text{Ch}_{(\tilde{x}, \tilde{\mu})} ([\tilde{a}, \tilde{b}]; q_1, q_2) = (1 - q_1) \sum_{k=1}^{n} V_{k-1}^* (\tilde{b}, \tilde{\mu}) V_{k} (\tilde{a}, \tilde{\lambda}) + q_1 \sum_{k=1}^{n} V_{k-1}^* (\tilde{b}, \tilde{\mu}) W_k (\tilde{a}) - 
\sum_{k=1}^{n} (1 - q_1) V_{k}^* (\tilde{b}, \tilde{\mu}) V_{k} (\tilde{a}, \tilde{\lambda}) + \sum_{k=1}^{n} W_k^* (\tilde{b}) V_{k} (\tilde{a}, \tilde{\lambda}),
$$

(109)

where $W_k (\tilde{a}) := e^{a_k} q_2$ and

$$
V_k (\tilde{a}, \tilde{\lambda}) := \sum_{0 \leq m} \sum_{\ell=1}^{k} e^{\alpha_k - \ell + \frac{1}{2}} q_2^{m - \frac{1}{2} (m + 1)} \sum_{j=1}^{\lambda (k - \ell + 1)} q_1^{-j} = 
\sum_{0 \leq m} \left( \sum_{\ell=1}^{k} e^{\alpha_k - \ell + \frac{1}{2}} \sum_{(i, m + \ell + 1) \in \lambda (k - \ell + 1)} q_1^{i} q_2^{m} + \sum_{\ell=k+1}^{n} e^{\alpha_k - \ell + \frac{1}{2}} \sum_{(i, m + \ell + 1) \in \lambda (k - \ell + 1)} q_1^{i} q_2^{m} \right).
$$

(110)

To eliminate the floor function in the formula (110) we use that fact that when $1 \leq k, \ell, \tilde{\ell} \leq n$ the arguments $X$ in the floor function appearing the formula satisfies $-1 < X < 1$. Therefore we have either $|X| = 0$ for $0 \leq X < 1$ or $|X| = -1$ for $-1 < X < 0$, respectively. Then we can see that (109) is nothing but the $\mathbb{Z}_n$ invariant (the charge zero part of\(\text{2}\))

$$
\chi_{(x, \mu)} (a_\alpha, b_\alpha; q_1) = -(1 - q_1) (1 - q_2^k) V_{k, \mu}^* \otimes V_{\alpha, \lambda} + W_k^* \otimes V_{\alpha, \lambda} + q_1 q_2 W_{k, \mu}^* \otimes W_{\alpha},
$$

(111)

namely

$$
\chi_{(x, \mu)}^\nu (a_\alpha, b_\alpha; q_1) = -(1 - q_1) \sum_{k=1}^{n} (V_{k, \mu}^* k) \otimes (V_{\alpha, \lambda} k) + (1 - q_1) \sum_{k=1}^{n} (V_{k, \mu}^* k-1) \otimes (V_{\alpha, \lambda} k)

+ \sum_{k=1}^{n} (W_{k, \mu}^* k) \otimes (V_{\alpha, \lambda} k) + q_1 \sum_{k=1}^{n} (V_{k, \mu}^* k-1) \otimes (W_{\alpha} k),
$$

(112)

where $W_n \equiv W_0$ and $V_n \equiv V_0$ with

$$
(W_{\alpha}) k = e^{a_k} q_2^{1 - \frac{k}{n}},
$$

(113)

and

$$
(V_{\alpha, \lambda}) k = \sum_{\ell=0}^{k-1} e^{\alpha_k - \ell} q_2^{\frac{k-\ell}{2}} \left( \sum_{(i, m + \ell + 1) \in \lambda (k - \ell)} q_1^{i} q_2^{m - \frac{j}{2}} \right) +
\sum_{\ell=k}^{n-1} e^{\alpha_k - \ell + n} q_2^{\frac{n-\ell}{2}} \left( \sum_{(i, m + \ell + 1) \in \lambda (k - \ell + n)} q_1^{i} q_2^{m - \frac{j}{2}} \right) =
$$

(114)

$$
= \sum_{\ell=1}^{k} e^{\alpha_k - \ell + 1} q_2^{1 - \frac{k}{2}} \left( \sum_{(i, m + \ell + 1) \in \lambda (k - \ell + 1)} q_1^{i} q_2^{m} \right) + \sum_{\ell=k+1}^{n} e^{\alpha_k - \ell + n + 1} q_2^{1 - \frac{k}{2}} \left( \sum_{(i, m + \ell + 1) \in \lambda (k - \ell + n + 1)} q_1^{i} q_2^{m} \right)
$$

Note that the $\mathbb{Z}_n$ fractional charge of $W_k$ and $V_k$ defined by (113) and (114) is $(1 - k/n)$ and we have rescaled

them by multiplying $q_2^{k/n}$ so that they have unit charge.

It is known that there are two ways of computing the instanton partition function with a monodromy (surface) defect [22, 54]. One is the orbifold construction described above and the other is the degenerate gauge vertex construction in the quiver gauge theory, where we tune the Coulomb moduli and mass parameters. It was argued that the two constructions are related by the brane transition in $M$ theory so that they are dual in IR [60]. The fact that the Shiraiishi function $\mathfrak{P}_n (x; p|y; s|q, t)$ agrees with the holomorphic block of $T[U(n)]$ theory in $p \to 0$ limit is in accord with the second description in terms of the quiver gauge theory. Note that the network diagram for $T[U(n)]$ theory is what is called Higgsed network in [38].

\[\text{2} \text{ Compare it with (106).}\]

\[\text{3} \text{In the AGT dictionary, this corresponds to the insertion of a fully degenerate primary field.}\]
