Abstract: We apply Sen’s entropy formalism to the study of the near horizon geometry and the entropy of asymptotically AdS black holes in gauged supergravities. In particular, we consider non-supersymmetric electrically charged black holes with $AdS_2 \times S^{d-2}$ horizons in $U(1)^4$ and $U(1)^3$ gauged supergravities in $d = 4$ and $d = 5$ dimensions, respectively. We study several cases including static/rotating, BPS and non-BPS black holes in Einstein as well as in Gauss-Bonnet gravity. In all examples, the near horizon geometry and black hole entropy are derived by extremizing the entropy function and are given entirely in terms of the gauge coupling, the electric charges and the angular momentum of the black hole.

Keywords: Black holes, attractors, AdS/CFT.
1. Introduction

The study of black hole thermodynamics has played a central role in the development of our current notions of holography in gravity. In this line of thinking, black holes are viewed as thermodynamic objects at equilibrium with a temperature and an entropy. A simple analysis of this thermodynamic system leads to the remarkable Bekenstein-Hawking formula for the black hole entropy. This formula relates the entropy of the black hole to the area of its horizon and it suggests that the microscopic degrees of freedom of the black hole can be described by a “dual” quantum mechanics living on the horizon. This is further supported by the discovery of AdS/CFT dualities [1] that relate gravity on AdS spaces and gauge theories living on the AdS boundary. These observations drastically simplify the study of black hole physics, since the geometry of the horizon is typically much simpler than that of the full solution.
Even in theories with scalar fields and a large number of moduli – asymptotic values of massless scalars at infinity –, scalars are attracted at the black hole horizon to special values and the full geometry is entirely determined in terms of the black hole charges. This is referred as the attractor mechanism [2–5]. Originally discussed in the context of $\mathcal{N} = 2$ black holes the attractor mechanism has been recently extended in many directions, including non-supersymmetric and higher derivative gravity theories [6–19]. The results show that the attractor mechanism is a universal issue of any gravity theory.

In [20], A. Sen introduced a unifying formalism, the entropy formalism, that describes the attractor equations and black hole entropy in a general non-supersymmetric and higher derivative gravity theory. In this formalism, the near horizon geometry is determined by extremizing a single function $F$, the entropy function. The entropy of the black hole is given by the value of $F$ at the extremum. The function $F$ is defined by the Legendre transform with respect to the black hole charges of the gravity action evaluated at the horizon. More precisely, the gravity action is first evaluated at a trial background geometry with volumes and scalar/gauge field profiles parametrized by a finite number of parameters. These parameters are then determined by extremizing the entropy function $F$. The formalism has been successfully applied to the study of general non-supersymmetric asymptotically flat black holes in various supergravity settings [21–32].

The aim of this paper is to extend this analysis to the study of asymptotically AdS black holes in gauged supergravities. According to holography [1] the entropy of black holes in AdS spaces is related to the free energy of the dual gauge theory living on the AdS boundary, see [33–38]. To pursue the study of these holographic correspondences a detailed knowledge of the black hole near horizon data is required. To derive explicit formulas for the attractor geometry and for the entropy of AdS black holes is one of the main motivations of the present work.

Black holes in gauged supergravities are different from those in Poincaré supergravities in many respects. First, in the gauged theory the asymptotic values of the scalar fields at infinity are typically fixed at the minimum of a scalar potential. The moduli space is therefore reduced and often empty. Still once charges are placed on $AdS_d$, even scalars fixed at infinity flow at the horizon to a different fixpoint specified completely by the black hole charges. I.e. the attractor mechanism now describes a flow between two fixpoint geometries. Second, it is well known that asymptotically AdS black hole solutions with regular horizons are always non-supersymmetric unless a non-trivial angular momentum is turned on. This is very different from the Minkowski case where BPS static solutions are quite common. Our analysis here explores both non-supersymmetric static and rotating black hole solutions.

We apply the entropy formalism to non-supersymmetric black holes with near horizon geometry $AdS_2 \times S^{d-2}$ in $d = 4, 5$. Black holes with these type of horizons

1More precisely, in the case of rotating black holes the horizons are described by a “squashed
have always zero temperature (with coinciding inner and outer horizons) but they are in general non-supersymmetric. For concreteness we focus on the $U(1)^4$ and $U(1)^3$ gauged supergravities in $d = 4$ and $d = 5$, respectively. These theories can be embedded into the maximal gauged supergravities with gauge groups $SO(8)$ and $SO(6)$, respectively, following from compactifications of M-theory and type IIB theory on $AdS_4 \times S^7$ and $AdS_5 \times S^5$, respectively. Black holes in these gauged supergravities have been extensively studied and classified in full generality in the literature [39–50] (see [51] for a review and a list of references). In the case of Einstein gravity, the solutions derived here via the entropy formalism follow from these general solutions by taking the zero temperature limit. Our focus here is on the near horizon geometry and black hole entropy.

We test the entropy formalism in a number of examples, including static/rotating black holes with or without supersymmetry in Einstein as well as Gauss-Bonnet gravity. In each case we show that the attractor geometry follows from extremization of the entropy function. In the case of Einstein gravity the entropy function output will be shown in agreement with the Bekenstein-Hawking formula as expected.

The entropy formalism is particularly efficient in the study of black holes in higher derivative gravity. Higher derivative corrections to black hole entropies in rigid supergravities were first studied in [52–55]. Higher derivative corrections to asymptotically AdS black holes in Gauss-Bonnet gravity were studied in [56]. More recently in [57] the authors consider several examples of higher derivative terms and derive the first corrections to the Schwarzschild AdS black holes. Here we consider the Einstein-Maxwell system in the presence of a Gauss-Bonnet term and derive exact expressions for the near horizon geometry and the black hole entropy.

The paper is organized as follows: In sections 2 and 3 we consider non-rotating asymptotically AdS black holes in $U(1)^4$ and $U(1)^3$ gauged supergravities in $d = 4$ and $d = 5$, respectively. In section 4 we apply the entropy formalism to rotating black holes in $d = 5$ gauged supergravity. The study of higher derivative corrections is sketched in section 5 for the Gauss-Bonnet type of interactions in the Maxwell-Einstein system in $d = 4, 5$ dimensions. In Section 6 we summarize our results and draw some conclusions. Appendix [A] contains a discussion on the normalization of the physical charges used in the main text. Appendix [B] presents the link between our $AdS_2 \times S^{d-2}$ solutions and zero temperature limits of the general black hole solutions.

2. AdS$_4$ static black holes

We start by considering $U(1)^4$ gauged supergravity in four dimensions. This theory follows from a truncation of the maximal $N = 8$, $SO(8)$ gauged supergravity [58].
down to the Cartan subgroup of $SO(8)$. The bosonic action can be written as [41]:

$$ S = \frac{1}{16 \pi G_4} \int d^4x \sqrt{-g} \left[ R - \frac{1}{4} X_I^2 F^I_{\mu\nu} F^{I\mu\nu} - \frac{1}{2} X_I^{-2} \partial_\mu X_I \partial^\mu X_I - V \right], \quad (2.1) $$

with $I = 1, \ldots, 4$, and

$$ F^I_{\mu\nu} = 2 \partial_\mu A_I^\nu, \quad V = -4 g^2 \sum_{I<J} X_I X_J, \quad X_1 X_2 X_3 X_4 = 1. \quad (2.2) $$

The equations of motion derived from this lagrangian are:

$$ R_{\mu\nu} - \frac{1}{2} X_I^2 F^I_{\mu\sigma} F^{I\sigma}_{\nu} - \frac{1}{2} X_I^{-2} \partial_\mu X_I \partial_\nu X_I - \frac{1}{2} g_{\mu\nu} \left( R - \frac{1}{4} X_I^2 F^{I2} - \frac{1}{2} (X_I^{-1} \partial X_I)^2 - V \right) = 0, $$

$$ \frac{\delta}{\delta X_I} \left( \frac{1}{4} X_I^2 F^{I2} + \frac{1}{2} (X_I^{-1} \partial X_I)^2 + V \right) = 0, $$

$$ \partial_\mu (\sqrt{-g} X_I^2 F^{I\mu\nu}) = 0. \quad (2.3) $$

We look for non-rotating black hole solutions with $AdS_2 \times S^2$ near horizon geometry

$$ ds^2 = v_1 \left( -r^2 dt^2 + \frac{dr^2}{r^2} \right) + v_2 d\Omega_2, \quad X_I = u_I, \quad A^I = -e_I r dt, \quad F^I_{0r} = e_I, $$

$$ d\Omega_2 = (d\theta^2 + \sin^2 \theta d\phi^2) \quad 0 \leq \theta \leq \pi \quad 0 \leq \phi < 2\pi. \quad (2.4) $$

with constants $u_I, e_I, v_a$, and $u_4 = 1/(u_1 u_2 u_3)$.

The attractor equations determining the constants $u_I, v_a, e_I$ at the black hole horizon are efficiently described by the so called entropy formalism [20]. One starts by evaluating the supergravity action (integrated on the $S^2$ horizon) in the background (2.4):

$$ f(\vec{e}, \vec{v}, \vec{u}) \equiv \int d\theta d\phi \sqrt{-g} L(\vec{e}, \vec{v}, \vec{u}), \quad (2.5) $$

with $L(\vec{e}, \vec{v}, \vec{u})$ the Lagrangian density evaluated on the ansatz (2.4). The entropy function $F(\vec{q}, \vec{e}, \vec{v}, \vec{u})$ is then defined as the Legendre transform of $f$ with respect to the charges $e_I$, i.e.

$$ F(\vec{q}, \vec{e}, \vec{v}, \vec{u}) \equiv 2\pi \left[ e_I q^I - f(\vec{e}, \vec{v}, \vec{u}) \right] $$

$$ = 2\pi \left[ e_I q^I - \frac{v_1 v_2}{4G_4} \left( -\frac{2}{v_1} + \frac{2}{v_2} + \sum_{I=1}^{4} \frac{u_I^2 e_I^2}{2v_I^2} + 4g^2 \sum_{I<J}^{4} u_I u_J \right) \right]. \quad (2.6) $$

The near horizon geometry can be found by extremizing the entropy function $F(\vec{q}, \vec{e}, \vec{v}, \vec{u})$ with respect to $\vec{e}, \vec{v},$ and $\vec{u}$:

$$ \frac{\partial F}{\partial v_a} = \frac{\partial F}{\partial u_I} = \frac{\partial F}{\partial e_I} = 0. \quad (2.7) $$
The first two equations ensure that the metric and the scalar field equations of motion are satisfied, while the last equation defines the black hole electric charges \( q^I \)

\[
q^I = \frac{\delta}{\delta e_I} f(\vec{e}, \vec{v}, \vec{u}) = \frac{v_2}{4 G_4 v_1} u_I^2 e_I = -\frac{1}{16\pi G_4} \int_{S^2} X_I^2 \ast F^I .
\]

(2.8)

In the following we will take \( G_4 = \frac{1}{8} \) in such a way that the charges \( q^I \) are normalized to be integers. This normalization is determined in Appendix A by matching the physical charge units here with those coming from string theory brane setups. The \( G_4 \) dependence can be restored by the rescaling (A.9) of the physical charges \( q^I \).

Evaluating the entropy function \( F \) at the extremum \( (\vec{e}_0(\vec{q}), \vec{v}_0(\vec{q}), \vec{u}_0(\vec{q})) \) one finds the entropy of the corresponding black hole solution as a function of the electric charges \( \vec{q} \):

\[
S_{BH}(\vec{q}) = F(\vec{q}, \vec{e}_0(\vec{q}), \vec{v}_0(\vec{q}), \vec{u}_0(\vec{q})) .
\]

(2.9)

In practice, the relations (2.8) are highly nonlinear and generically hard to invert, therefore we will often choose to give an implicit parametrization of the black hole solution, its entropy, and the electric charges \( q^I \) in terms of \( u_{1,2,3} \) and \( v_2 \) rather than expressing the entropy directly in terms of the four physical charges \( q^I \).

It is important to stress that the entropy function formalism applies to (in general non-supersymmetric) higher derivative Lagrangians that depend only on the Riemann and the stress energy tensor but not on their covariant derivatives. In this section we consider Einstein gravity, while higher derivative corrections to black hole entropies will be considered in section 4.

2.1 The solution

As we mentioned in our preliminary discussion, it is often easier to solve equations (2.7), (2.8) implicitly in terms of a set of independent parameters rather than in terms of the four charges \( q^I \). We choose parameters \( \mu_I \) to parametrize the fixed value scalars \( u_{1,2,3} \) and the sphere volume \( v_2 \):

\[
u_I = \frac{\mu_I}{(\mu_1 \mu_2 \mu_3 \mu_4)^{1/4}} , \quad v_2 = \frac{1}{4} \sqrt{\mu_1 \mu_2 \mu_3 \mu_4} ,
\]

(2.10)

Plugging (2.10) into (2.7) and solving for the remaining variables, one finds the general solution:

\[
v_1 = \frac{\frac{1}{4} \sqrt{\mu_1 \mu_2 \mu_3 \mu_4}}{1 + g^2 \sum_{J<K} \mu_J \mu_K} , \quad e_I = \frac{\sqrt{\mu_1 \mu_2 \mu_3 \mu_4 \left(1 + g^2 \sum_{J<K \neq I} \mu_J \mu_K \right)}}{2 \mu_I \left(1 + g^2 \sum_{J<K} \mu_J \mu_K \right)} , \quad q^I = \mu_I \sqrt{1 + g^2 \sum_{J<K \neq I} \mu_J \mu_K} .
\]

(2.11)
It is easy to check that the equations of motion (2.3) are satisfied by (2.4), (2.10), (2.11). Plugging this into the entropy function (2.6) yields for the black hole entropy

\[ S_{BH}(q) = 2\pi \sqrt{\mu_1 \mu_2 \mu_3 \mu_4} = \frac{\pi v_2}{G_4} = \frac{1}{4G_4} A_{hor}, \]  
(2.12)

in agreement with the Bekenstein-Hawking formula.

In order to express the entropy directly in terms of the electric charges \( q^I \), one has to invert the last equation in (2.11). In lowest orders of the gauge coupling this gives rise to the expansion

\[ \mu_I = q^I \left( 1 - \frac{1}{2} g^2 \partial_I \beta_3 + \frac{1}{8} g^4 \left( \partial_I (3\beta_2 \beta_3 + \beta_1 \beta_4) - 2q^I \partial_I^2 (\beta_2 \beta_3 + 4\beta_4) + \ldots \right) \right), \]
(2.13)

in terms of the symmetric polynomials

\[ \beta_1 = \sum_I q^I, \quad \beta_2 = \sum_{I<J} q^I q^J, \quad \beta_3 = \sum_{I<J<K} q^I q^J q^K, \quad \beta_4 = q_1 q_2 q_3 q_4, \]

and with \( \partial_I = \frac{\partial}{\partial q^I} \). For the entropy this leads to the expansion

\[ S_{BH} = 2\pi \sqrt{\beta_4} \left( 1 - \frac{1}{2} g^2 \beta_2 + \frac{1}{8} g^4 \left( 3\beta_2^2 + 2\beta_1 \beta_3 + 4\beta_4 \right) \right. \]
\[ \left. - \frac{1}{16} g^6 \left( 5\beta_2^3 + 9\beta_1 \beta_2 \beta_3 + 5\beta_3^3 + 20\beta_2 \beta_4 \right) + \ldots \right). \]
(2.14)

The expansion drastically simplifies in two particular cases:

**Ungauged theory**

At \( g = 0 \) one finds \( q^I = \mu_I \) leading to:

\[ v_1 = v_2 = \frac{1}{4} \sqrt{q_1 q_2 q_3 q_4}, \quad u_I = \frac{q^I}{(q_1 q_2 q_3 q_4)^{1/4}}, \quad e_I = \frac{1}{2q^I} \sqrt{q_1 q_2 q_3 q_4}, \]
(2.15)

and one recovers the known result

\[ S_{BH}(\vec{q}) = 2\pi \sqrt{q_1 q_2 q_3 q_4}, \]  
(2.16)

for the entropy in terms of the physical charges.

**Equal charges** \( q^I = q \)

In the case of equal charges, the last equation in (2.11) can be explicitly solved for \( \mu \) and one obtains the explicit solution

\[ v_1 = \frac{\sqrt{1 + 12g^2 q^2} - 1}{24g^2 \sqrt{1 + 12g^2 q^2}}, \quad v_2 = \frac{\sqrt{1 + 12g^2 q^2} - 1}{24g^2}, \quad u_I = 1, \]
\[ e_I = \frac{q}{2\sqrt{1 + 12g^2 q^2}}, \]
(2.17)
and the black hole entropy

\[ S_{\text{BH}}(q) = \frac{\pi (\sqrt{1 + 12q^2g^2} - 1)}{3g^2}, \]  

expressed directly in terms of the electric charges \( q \).

### 3. AdS\(_5\) static black holes

Next we consider the U(1)\(^3\) gauged supergravity in \( d = 5 \) dimensions. This theory can be obtained as a truncation of the maximal \( N = 8 \), SO(6) gauged supergravity \[59\] down to the U(1)\(^3\) Cartan subgroup of SO(6). The bosonic action can be written as

\[
S = \frac{1}{16\pi G_5} \int d^5 x \sqrt{-g} \left[ R - \frac{1}{4} X_I^2 F_{\mu\nu}^{I} F^{\mu\nu I} - \frac{1}{2} X_I^{-2} \partial_\mu X_I \partial^\mu X_I - V + \frac{1}{2\pi} \omega^{\mu\nu\rho\lambda} |\epsilon_{IJK}| F_{\mu\nu}^{I} F_{\sigma\rho}^{J} A^K_{\lambda} \right],
\]

with \( I = 1, 2, 3 \), \( \omega^{tr\psi\phi} = - (\sqrt{-g})^{-1} \), and

\[ F_{\mu\nu}^{I} = 2 \partial_\mu A_{\nu}^{I}, \quad V = -4g^2 \sum_{I=1}^{3} X_I, \quad X_1X_2X_3 = 1. \]  

The equations of motion derived from this Lagrangian are:

\[
R_{\mu\nu} - \frac{1}{2} X_I^{-2} \partial_\mu X_I \partial_\nu X_I - \frac{1}{2} g_{\mu\nu} \left( R - \frac{1}{4} X_I^2 F_{\mu\lambda}^{I} F^{\mu\lambda I} - \frac{1}{2} (X_I^{-1} \partial X_I)^2 - V \right) = 0,
\]

\[
\frac{\delta}{\delta X_I} \left( \frac{1}{4} X_I^2 F_{\mu\nu}^{I} F^{\mu\nu I} + \frac{1}{2} (X_I^{-1} \partial X_I)^2 + V \right) = 0,
\]

\[
\frac{1}{\sqrt{-g}} \partial_\mu (\sqrt{-g} X_I^2 F_{\mu\lambda}^{I}) + \frac{1}{8} |\epsilon_{IJK}| \omega^{\mu\nu\rho\lambda} F_{\mu\nu}^{I} F_{\sigma\rho}^{J} A^K_{\lambda} = 0. \]

We search for non-rotating black holes with near horizon \( AdS_2 \times S^3 \) geometries

\[
ds^2 = v_1 \left( -r^2 dt^2 + \frac{dr^2}{r^2} \right) + v_2 d\Omega_3,
\]

\[ X_I = u_I, \quad A_I = -e_I r dt, \quad F_{0r}^I = e_I, \]  

\[ d\Omega_3 = \frac{1}{4} \left[ d\theta^2 + d\psi^2 + d\phi^2 + 2d\phi \, d\psi \, \cos \theta \right], \quad 0 \leq \psi \leq 2\pi, \quad 0 \leq \phi \leq 4\pi, \quad 0 \leq \theta \leq \pi,
\]

with constants \( u_I, e_I, v_a \), and \( u_3 = 1/(u_1u_2) \).

As before we denote by \( f(\vec{e}, \vec{v}, \vec{u}) \), the supergravity action evaluated on the background (3.4) and integrated over the three-sphere:

\[
f(\vec{e}, \vec{v}, \vec{u}) \equiv \int d\theta d\phi \, d\psi \sqrt{-g} \, \mathcal{L}(\vec{e}, \vec{v}, \vec{u}).
\]
The entropy function $F(\vec{q}, \vec{e}, \vec{v}, \vec{u})$ is again defined as the Legendre transform of $f$ with respect to the charges $e_I$, i.e.

$$F(\vec{q}, \vec{e}, \vec{v}, \vec{u}) \equiv 2\pi \left[ e_I q^I - f(\vec{e}, \vec{v}, \vec{u}) \right] = 2\pi \left[ e_I q^I - \frac{\pi}{8} v_1^2 \frac{3}{2} - \frac{2}{v_1} + \frac{6}{v_2} + \sum_I \frac{u_I^2 e_I^2}{2v_1^2} + 4g^2 \sum_I u_I \right].$$ (3.6)

Note that the Chern-Simons term does not contribute to the action in the near horizon geometry (3.4). The near horizon geometry is again found by extremizing $F$:

$$\frac{\partial F}{\partial e_I} = \frac{\partial F}{\partial v_a} = \frac{\partial F}{\partial u_I} = 0. \quad \text{(3.7)}$$

The first equation defines the electric charges $q^I$ as

$$q^I = \delta \frac{\delta}{\delta e_I} f(\vec{e}, \vec{v}, \vec{u}) = \frac{\pi v_2^4}{8G_5 v_1} u_I^2 v_2 = -\frac{1}{16\pi G_5} \int_{S^3} X^2_{I} * F^I. \quad \text{(3.8)}$$

In the following we will take $G_5 = \frac{\pi}{4}$ in such a way that the charges $q^I$ are normalized to be integers. This normalization is justified in Appendix A. The $G_5$ dependence can be restored by the rescaling (A.11) of the physical charges $q^I$.

Evaluating the entropy function at the minimum $\left(\vec{e}_0(\vec{q}), \vec{v}_0(\vec{q}), \vec{u}_0(\vec{q})\right)$ one finds the entropy of the corresponding black hole solution as a function of the electric charges $\vec{q}$.

$$S_{BH}(\vec{q}) = F(\vec{q}, \vec{e}_0(\vec{q}), \vec{v}_0(\vec{q}), \vec{u}_0(\vec{q})). \quad \text{(3.9)}$$

### 3.1 The solution

In analogy to the four-dimensional case above we introduce three independent parameters $\mu_I$ to parametrize $u_{1,2}$ and $v_2$. The general solution of (3.7) can then be written as

$$u_I = \frac{\mu_I}{(\mu_1 \mu_2 \mu_3)^{1/3}}, \quad v_2 = (\mu_1 \mu_2 \mu_3)^{1/3},$$

$$v_1 = \frac{(\mu_1 \mu_2 \mu_3)^{1/3}}{4(1 + g^2 \sum_{J \neq I} \mu_J)}, \quad e_I = \frac{\sqrt{\mu_1 \mu_2 \mu_3} (1 + g^2 \sum_{J \neq I} \mu_J)}{2 \mu_I (1 + g^2 \sum_{J \neq I} \mu_J)},$$

$$q^I = \mu_I \sqrt{1 + g^2 \sum_{J \neq I} \mu_J}. \quad \text{(3.10)}$$

It is easy to check that equations of motion (3.3) are satisfied by (3.4), (3.10). With this solution we obtain from (3.6) for the entropy of the black hole

$$S_{BH} = 2\pi \sqrt{\mu_1 \mu_2 \mu_3} = \frac{\pi^2 v_2^4}{2G_5} = \frac{1}{4G_5} A_{\text{hor}}, \quad \text{(3.11)}$$
again in agreement with the Bekenstein-Hawking formula.

In lowest order of the gauge coupling we obtain the following expansion
\[
\mu_l = q^l \left(1 - \frac{1}{2} g^2 \partial_l \beta_2 + \frac{1}{8} g^4 (\partial_l (3\beta_1 \beta_2 + 5\beta_3) - 4\beta_2) + \ldots\right),
\]
(3.12)
in terms of the symmetric polynomials
\[
\beta_1 = \sum_i q^i, \quad \beta_2 = \sum_{i<j} q^i q^j, \quad \beta_3 = q_1 q_2 q_3.
\]
For the entropy this implies
\[
S_{\text{BH}} = 2\pi \sqrt{\beta_3} \left(1 - \frac{1}{2} g^2 \beta_1 + \frac{1}{8} g^4 (3\beta_1^2 + 2\beta_2) - \frac{1}{16} g^6 (5\beta_1^3 + 9\beta_1 \beta_2 + 5\beta_3)
+ \frac{1}{128} g^8 (35 \beta_1^4 + 116 \beta_1^2 \beta_2 + 20 \beta_2^2 + 136 \beta_1 \beta_3) + \ldots\right)\quad (3.13)
\]
Again drastic simplifications occur for \(g = 0\) and for all charges equal \(q^l = q\):

**Ungauged theory**

At \(g = 0\) we have \(\mu_l = q^l\) and the solution takes the explicit form
\[
v_2 = 4v_1 = (q_1 q_2 q_3)^{\frac{1}{3}}, \quad u_l = \frac{q^l}{(q_1 q_2 q_3)^{\frac{1}{3}}}, \quad e_l = \frac{1}{2q^l} \sqrt{q_1 q_2 q_3},
\]
(3.14)
and the black hole entropy is simply given as
\[
S_{\text{BH}} = 2\pi \sqrt{q_1 q_2 q_3}.
\]
(3.15)

**Equal charges** \(q^l = q\)

In this case the above formulas reduce to
\[
v_1 = \frac{\mu}{4(1 + 3g^2 \mu)}, \quad v_2 = \mu, \quad u_l = 1, \quad e_l = \frac{\sqrt{\mu + 2g^2 \mu^2}}{2(1 + 3g^2 \mu)}, \quad q = \mu \sqrt{1 + 2g^2 \mu},
\]
(3.16)
with black hole entropy
\[
S_{\text{BH}} = 2\pi \mu^{3/2} = \frac{\pi^2 v_2^{\frac{2}{3}}}{2G_5} = \frac{1}{4G_5} A_{\text{hor}},
\]
(3.17)
expressed in terms of a single parameter \(\mu\). If instead we choose to express \(S_{\text{BH}}\) directly in terms of the charges \(q\) we have to invert the last equation in (3.16). A closed form for the entropy in this case is given by the more involved expression
\[
S_{\text{BH}} = \frac{2\sqrt{3} q^{3/2}}{\sqrt{\sin \phi + \sqrt{3} \cos \phi + (2/3) \sin 3\phi}}, \quad \phi = \frac{1}{3} \arcsin(3\sqrt{3} q g^2).
\]
(3.18)
4. Rotating black holes in AdS$_5$

Finally we consider rotating black holes with squashed $AdS_2 \times S^3$ near horizon geometry$^2$

\[ ds^2 = v_1 \left( -r \, dt^2 + \frac{dr^2}{r^2} \right) + \frac{r^2}{4} v_2 \left[ \sigma_1^2 + \sigma_2^2 + v_3(\sigma_3 - \alpha \, r \, dt)^2 \right] , \]
\[ X_I = u_I , \]
\[ A^I = -e_I \, r \, dt + p_I \, \sigma_3 , \quad F_{0r}^I = e_I , \quad F_{\psi \theta}^I = p_I \, \sin \theta , \]
\[ \sigma_1^2 + \sigma_2^2 = d\theta^2 + \sin^2 \theta d\psi^2 , \quad \sigma_3 = d\phi + \cos \theta d\psi , \tag{4.1} \]

with constants $u_I, e_I, p_I, v_a$, and $\alpha$. The constants $\alpha, v_3$ and $p_I$ parametrize the breaking from the $SO(4)$ isometry of the non-rotating solution down to $SU(2) \times U(1)$ once the angular momentum is turned on.

The entropy function is then given by [29]

\[ F(\vec{q}, \vec{e}, \vec{v}, \vec{u}) \equiv 2\pi \left( \alpha J + e_I \, \hat{q}_I - f(e_I, \alpha, v_a, u_I) \right) \]
\[ = 2\pi \left[ \alpha J + e_I q^I + \frac{\pi}{3G_5} \left| \epsilon_{IJK} \right| e_I p_{JK} \right] \]
\[ - \frac{\pi v_1 v_2^2 v_3^2}{8G_5} \left( \frac{2}{v_1} \frac{8 - 2v_3}{v_2} + \frac{v_2 v_3 \alpha^2}{8v_1^2} + \sum_j \frac{e_j^2 u_j^2}{2v_1^2} - 8 \sum_j \frac{p_j^2 u_j^2}{v_2^2} + 4g^2 \sum_j u_I \right) . \tag{4.2} \]

Notice that now also the Chern-Simons term contributes to the action. The fact that the Chern-Simons term depends explicitly on the potential $A_\mu$ rather than on the field strength $F_{\mu\nu}$ requires a slight modification of Sen’s algorithm. First, the presence of the Chern-Simons term modifies the definition of the electric charge $q^I$.

This can be easily implemented in the entropy function by the redefinition $q^I = \hat{q}^I + c^I$ with $c^I$ chosen such that $q^I$ are conserved quantities. Luckily the $c^I$ induced by the Chern-Simons term are independent of $e_I, u_I$, and $v_a$ such that this modification will modify neither the attractor equations nor the black hole entropy. Second, due to the presence of the Chern-Simons term, the equations of motion for $A^I_\phi$

\[ 0 = \frac{1}{\sqrt{-g}} \partial_\mu (\sqrt{-g} \, X_I^2 \, F^{\mu \phi I}) + \frac{1}{8} |\epsilon_{IJK}| \omega^{\mu \lambda \rho \phi} F^I_{\mu \lambda} F^K_{\sigma \rho} , \]
\[ = \frac{\alpha u_1^2 e_1}{v_1^2} - \frac{16 u_1^2 p_1}{v_2^2} - \frac{8}{v_1 v_2^2 v_3^2} |\epsilon_{IJK}| \, e^J V^K , \tag{4.3} \]

are no longer automatically satisfied as a mere consequence of the extremization equations

\[ \frac{\partial F}{\partial \alpha} = \frac{\partial F}{\partial e_1} = \frac{\partial F}{\partial u_I} = \frac{\partial F}{\partial v_a} = 0 . \tag{4.4} \]

---

$^2$Squashing here refers to the full product, still the metric has the AdS$_2$ isometries, see [60].
Rather, equations (4.3) have to be considered in addition to the extremization equations (4.4) and determine the fluxes $p_I$ in the ansatz (4.1).

The resulting solution describes the near horizon geometry of a black hole with electric charges $q^I$ and angular momenta $J$ given by

$$q^I = \frac{\delta}{\delta \epsilon_I} f(\vec{e}, \vec{v}, \vec{u}) - \frac{\pi}{6 G_5} |\epsilon_{IJK}| p_J p_K = \frac{\pi v_2^2 v_3^2 u_1^2}{8 G_5 v_1} e_I - \frac{\pi}{2 G_5} |\epsilon_{IJK}| p_J p_K$$

$$= - \frac{1}{16 \pi G_5} \int_{S^3} (X_I^2 * F^I + \frac{1}{2} |\epsilon_{IJK}| F^J \wedge A^K),$$

$$J = \frac{\delta}{\delta \alpha} f(\vec{e}, \vec{v}, \vec{u}) = \frac{\pi v_2^2 v_3^2}{32 G_5 v_1} \alpha = \frac{1}{16 \pi G_5} \int_{S^3} *dK. \tag{4.5}$$

Here $K = \frac{\partial}{\partial \phi}$ denotes the Killing vector associated with the angular rotation. The shift $c^I = - \frac{\pi v_2^2 v_3^2}{6 G_5} |\epsilon_{IJK}| p_J p_K$ has been chosen in such a way that the integrand in the definition of $q^I$ is closed on the mass shell

$$d(X_I^2 * F^I) + \frac{1}{2} |\epsilon_{IJK}| F^J \wedge F^K = 0. \tag{4.6}$$

This allow us to identify $q^I$ with the conserved charge\textsuperscript{3}. As we explained before neither the solution nor the entropy depends on the $c^I$'s. In the rest of this section we describe the different subcases for which we can give explicit solutions to (4.3), (4.4).

4.1 BPS black holes

Let us first discuss the case of extremal BPS rotating black holes. These black hole solutions have been found in [44].

In this case, we can give the general solution of (4.3), (4.4) again in terms of three independent parameters $\mu_I$ and their symmetric polynomials

$$\gamma_1 = \sum_I \mu_I, \quad \gamma_2 = \sum_{I<J} \mu_I \mu_J, \quad \gamma_3 = \mu_1 \mu_2 \mu_3,$$

\textsuperscript{3}J.F.M. thanks L.Alvarez-Gaume and C.N. Pope for useful discussions on this point.
as follows

\[ u_I = \frac{\mu_I}{\gamma_3^{1/3}}, \quad v_1 = \frac{\gamma_3^{1/3}}{4(1 + g^2 \gamma_1)}, \quad v_2 = \gamma_3^{1/3}, \quad v_3 = 1 + g^2 \gamma_1 - \frac{g^2 \gamma_2^2}{4 \gamma_3}, \quad \alpha = \frac{g \gamma_2}{(1 + g^2 \gamma_1) \sqrt{4 \gamma_3 (1 + g^2 \gamma_1) - g^2 \gamma_2^2}}, \]

\[ e_I = \frac{\sqrt{4 \gamma_3 (1 + g^2 \gamma_1) - g^2 \gamma_2^2}}{4 \mu_I (1 + g^2 \gamma_1)}, \quad p_I = \frac{1}{4} g (\gamma_1 - \mu_I) - \frac{g \gamma_3}{4 \mu_I^2}, \]

\[ q^I = \mu_I + \frac{1}{2} g^2 \mu_I (\gamma_1 - \mu_I) - \frac{g^2 \gamma_3}{2 \mu_I} \quad J = \frac{g \gamma_2 (4 \gamma_3 (1 + g^2 \gamma_1) - g^2 \gamma_2^2)}{16 \gamma_3}. \tag{4.7} \]

Plugging this into (4.2) we obtain for the entropy

\[ S_{BH} = 2 \pi \sqrt{\gamma_3 (1 + g^2 \gamma_1) - \frac{1}{4} g^2 \gamma_2^2} = \frac{\pi^2 v_1^2 v_2^2 v_3^2}{2 G_5} = \frac{1}{4 G_5} A_{hor}, \tag{4.8} \]

reproducing the result of [44]. In order to compare the results it is helpful to note that the parametrization of the squashed $AdS_2 \times S^3$ near horizon geometry given in [44]

\[ ds^2_{BPS} = -f^2 dT^2 + 2 f^2 w dT \sigma_3 + f^{-1} b^{-1} dR^2 + \frac{1}{4} R^2 f^{-1} (\sigma_1^2 + \sigma_2^2 + c \sigma_3^2), \quad f = R^2 \gamma_3^{-\frac{1}{4}}, \quad w = -\gamma_2 g, \quad b = 1 + g^2 \gamma_1, \quad c = 1 + g^2 \gamma_1 - \frac{g^2 \gamma_2^2}{4 \gamma_3}, \tag{4.9} \]

translates into the standard form (4.1) with

\[ r = R^2, \quad dt = \frac{2 b}{\sqrt{\gamma_3 c}} dT, \quad v_1 = \gamma_3^{\frac{1}{4}}, \quad v_2 = \gamma_3^{-\frac{1}{4}}, \quad v_3 = c, \quad \alpha = \frac{\gamma_2 g}{2 b \sqrt{\gamma_3 c}}. \]

in agreement with (4.7).

### 4.2 Non-extremal black holes

These considerations can be extended to non-extremal black holes. For simplicity we focus on the case of equal charges $q^I = q$. The general solution of equations (4.3), (4.4) can then be expressed in terms of two independent parameters $\mu, \omega > 1$ as

\[ u_I = 1, \quad v_1 = \frac{\mu}{4(1 + 3 g^2 \mu)}, \quad v_2 = \mu, \quad v_3 = \mu^{-3} \Delta_s^2, \tag{4.10} \]

\[ e_I = \frac{\Delta_s}{2 \mu (\omega - 1)(1 + 3 g^2 \mu)}, \quad p_I = \frac{\Delta_s}{2 \mu (1 + w)}, \quad \alpha = \frac{\Delta_s}{\Delta_s (1 + 3 g^2 \mu)}, \]

\[ J = \frac{1}{2} \mu^{-3} \Delta_s \Delta_s^2, \quad q^I = \frac{2 \mu}{\omega} + \frac{2 g^2 \mu^2 (\omega - 1)}{\omega^2}. \]
with
\[ \Delta_\alpha = \frac{\mu(\omega + 1)}{\omega^2} \sqrt{2\mu \omega (\omega - 2) + 4g^2 \mu^2 (\omega^2 - 2\omega + 1)}, \]
\[ \Delta_\omega = \frac{\mu(\omega - 1)}{\omega^2} \sqrt{2\mu \omega (\omega + 2) + 2g^2 \mu^2 (\omega^2 + 2\omega - 2)}. \] (4.11)

Plugging this into (4.2), we find for the entropy
\[ S_{\text{BH}} = 2\pi \Delta_\omega = \frac{\pi^2 v_1^2 v_3^3}{2G_5} = \frac{1}{4G_5} A_{\text{hor}}. \] (4.12)

It is interesting to note that although for a generic choice of the parameters \( \mu, \omega \) the black hole solution found here is non-supersymmetric, the charges can be chosen in such a way that the BPS bound is saturated. More precisely, for the particular value \( \omega = 2 \) the formulas obtained here reduce to
\[ u_I = 1, \quad e_I = \frac{\sqrt{\pi} \sqrt{4 + 3g^2 \mu}}{4(1 + 3g^2 \mu)}, \quad p_I = \frac{1}{4} g \mu, \quad q_I = \mu + \frac{1}{2} g^2 \mu^2, \]
\[ v_1 = \frac{\mu}{4(1 + 3g^2 \mu)}, \quad v_2 = \mu, \quad v_3 = 1 + \frac{3}{4} g^2 \mu, \quad \alpha = \frac{3g \sqrt{\mu}}{(1 + 3g^2 \mu) \sqrt{4 + 3g^2 \mu}}, \]
\[ J = \frac{3}{16} g \mu^2 (4 + 3g^2 \mu), \quad S_{\text{BH}} = 2\pi \mu^{3/2} \sqrt{1 + \frac{3}{4} g^2 \mu}, \] (4.13)
that agrees with the general BPS solution (4.7) after taking all charges equal \( \mu_i = \mu \).

Another interesting limit of the solution (4.10) is the unrotating case studied in last section. This is given by setting
\[ \omega = 1 + \frac{1}{\sqrt{1 + 2g^2 \mu}}. \] (4.14)

Indeed it is straightforward to check that at this value the above formulas reduce to (3.16).

5. Higher derivative terms

Finally we consider asymptotically Anti-de Sitter black hole horizons in higher derivative gravity. In contrast to the case of Poincaré supergravities, higher derivative couplings in gauged supergravities were rarely studied in the string literature. Awaiting more realistic Lagrangians here we illustrate the entropy formalism in an archetype toy example: the Einstein-Maxwell system in presence of a Gauss-Bonnet term and a cosmological constant
\[ S = \frac{1}{16\pi G_d} \int d^d x \sqrt{-g} \left( R - \frac{1}{4} F^2 + \Lambda + a L_{\text{GB}} \right), \] (5.1)
with the Gauss-Bonnet term

$$\mathcal{L}_{GB} = R_{\mu\nu\sigma\rho} R^{\mu\nu\sigma\rho} - 4 R_{\mu\nu} R^{\mu\nu} + R^2 . \tag{5.2}$$

The parameter $a$ measures the deviation from Einstein gravity and it depends on the particular string model under consideration.\(^4\)

The equations of motion following from (5.1) are:

$$R_{\mu\nu} - \frac{1}{2} F_{\mu\sigma} F^{\nu\sigma} + a \frac{\delta \mathcal{L}_{GB}}{\delta g^{\mu\nu}} - \frac{1}{2} g_{\mu\nu} \left( R - \frac{1}{4} F^2 + \Lambda + a \mathcal{L}_{GB} \right) = 0 ,$$

$$\partial_\mu (\sqrt{-g} F^{\mu\nu}) = 0 , \tag{5.3}$$

with

$$\frac{\delta \mathcal{L}_{GB}}{\delta g^{\mu\nu}} = 2 \left( R_{\mu\sigma\rho\delta} R^{\nu\sigma\rho\delta} - 2 R^{\nu\sigma} R_{\mu\nu\sigma} - 2 R^\rho_{\mu} R_{\nu\sigma} + R R_{\mu\nu} \right) , \tag{5.4}$$

up to total derivatives. We look for $AdS_2 \times S^{d-2}$ near horizon geometries:

$$ds^2 = v_1 \left( -r^2 dt^2 + \frac{dr^2}{r^2} \right) + v_2 d\Omega_{d-2} , \quad F_0 = e . \tag{5.5}$$

The extremization equations of the entropy function can now be explicitly solved in the different space-time dimensions.

**d=4**

In four dimensions, evaluating the entropy function for this system yields

$$F(q, e, \vec{v}) \equiv 2\pi \left[ eq - \frac{v_1 v_2}{4G_4} \left( -\frac{2}{v_1} + \frac{2}{v_2} - \frac{8a}{v_1 v_2} + \frac{e^2}{2v_1^2} + \Lambda \right) \right] . \tag{5.6}$$

The extremum of $F(q, e, \vec{v})$ (for a fixed $q$) can be conveniently parametrized in terms of $v_2$:

$$v_1 = \frac{v_2}{1 + v_2 \Lambda} , \quad e = \sqrt{\frac{2v_2 (2 + v_2 \Lambda)}{(1 + v_2 \Lambda)}} , \quad q = \frac{1}{2G_4} \sqrt{v_2 (1 + \frac{1}{2} v_2 \Lambda)} . \tag{5.7}$$

Plugging (5.7) into the entropy function (5.6) one finds the black hole entropy

$$S_{BH} = \frac{\pi}{G_4} (v_2 + 4a) . \tag{5.8}$$

The $a$-term gives the deviation from the area law due to the Gauss-Bonnet term. Interestingly, the presence of the Gauss-Bonnet term in $d = 4$ does not modify the near horizon solution but only the black hole entropy. This is consistent with the fact that in $d = 4$ the $a$-dependent term in the equations of motion (5.3) cancels once evaluated on $AdS_2 \times S^2$. In $d = 5$ this will be different as we shall see.

\(^4\)See [61–63] for an analysis of the boundary terms needed by the regularization of the action for Einstein-Gauss-Bonnet-AdS gravity.
In five dimensions the entropy function is given by

$$F(q, e, \vec{v}) \equiv 2\pi \left[ e q - \frac{\pi v_1 v_2^2}{8G_5} \left( \frac{-2}{v_1} + \frac{6}{v_2} - \frac{24a}{v_1 v_2} + \frac{e^2}{2v_1^2} + \Lambda \right) \right]. \quad (5.9)$$

The extremum of $F(q, e, \vec{v})$ (for a fixed $q$) can be conveniently parametrized in terms of the sphere radius $v_2$:

$$v_1 = \frac{v_2 + 4a}{4 - v_2\Lambda}, \quad e = \left( \frac{v_2 + 4a}{4 - v_2\Lambda} \right) \sqrt{12v_2^{-1} - 2\Lambda}, \quad q = \frac{\pi v_2}{4G_5} \sqrt{3 - \frac{1}{2}v_2\Lambda}. \quad (5.10)$$

Plugging (5.10) into the entropy function (5.9) one finds the black hole entropy

$$S_{BH} = \frac{\pi^2 v_2^{\frac{3}{2}}}{2G_5} (v_2 + 12a). \quad (5.11)$$

The $a$-dependent term represents the deviation from the area law due to the Gauss-Bonnet term.

6. Conclusions

In this paper we applied the entropy formalism to the case of gauged supergravities which admit asymptotically AdS electrically charged black holes with $AdS_2 \times S^{d-2}$ horizons. Using Sen’s algorithm we have determined the fixed near-horizon geometries for four and five-dimensional static black holes, for rotating five-dimensional black holes and finally for AdS black holes with higher derivative corrections of Gauss-Bonnet type. In each case we find horizons with fixed scalar, AdS and sphere radii, determined entirely in terms of the gauge coupling, the black hole electric charges and the angular momentum.

The explicit dependence on the gauge potential via the Chern-Simons term in the five-dimensional gauged supergravity requires a slight modification of the entropy function algorithm. We have illustrated this in the case of five-dimensional rotating black holes. Once the black hole rotates, magnetic fluxes $p_I$ should be turned on and the Chern-Simons term starts contributing to the action. The inclusion of this term leads to a redefinition of the black hole electric charge $q^I \rightarrow q^I + c^I$ with $c^I$ depending only on the magnetic fluxes and not on the metric or scalar fields. This implies in particular that neither the attractor equations nor the entropy depends on $c^I$ and therefore $c^I$ can be adjusted to account for the Chern-Simons correction to the electric charge. The fluxes $p_I$ are determined by an extra constraint coming from the gauge field equations of motion to be imposed in addition to the extremization conditions of the entropy function. Nicely, this leads again to a family of black hole
near horizon solutions parametrized only by the black hole electric charges and the angular momentum.

In the case of Einstein gravity, the near horizon geometries derived here can be recovered by considering the zero temperature limit of the general black hole solutions [39–50]. In this limit one finds a single horizon with $AdS_2 \times S^{d-2}$ topology. We stress the fact that in the gauged theory, zero temperature black holes are not necessarily supersymmetric. A non-BPS black hole solution is known to be classified by its charges (electric charge, angular momentum, etc.) and its mass. The condition of zero temperature relates the black hole mass to its charges. This implies that there is a unique black hole solution with $AdS_2 \times S^{d-2}$ horizon for a given choice of the charges. This is precisely the result coming from extremizing the entropy function. The precise matching between our solutions and the $T \to 0$ limit of the general non-extremal black hole solutions is shown explicitly in appendix B for static black holes and in section 4.1 for the five-dimensional BPS case [44].

It is tempting to speculate about the generalization of the expressions for the entropy (2.14), (3.13) to the full $\mathcal{N} = 8$ theories. For the ungauged case $g = 0$ it is well known that the first term in the expansions is replaced by the quartic and cubic invariants of the global symmetry groups $E_7$ and $E_6$, respectively [64]. The gauging of the theories is most conveniently described in terms of an embedding tensor which parametrizes the deformation in order $g$ and comes in a particular representation of the global symmetry groups [65]. This suggests that e.g. the second term in the expansion (2.14) will be replaced by an $E_7$ invariant built from six charges and two embedding tensors. Indeed, there is a single nontrivial $E_7$ invariant combination of these representations which might thus generalize the expansion (2.14) to lowest orders.

It would be nice to explore the implications of our results to gauge/gravity holographic correspondences. In particular, the $AdS_5$ entropy formula provide explicit predictions on the partition function of gauge invariant operators in $\mathcal{N} = 4$ SYM. In addition the $AdS_2 \times S^{d-2}$ solutions found here can be used as starting points of new holographic relations between quantum mechanical systems living on the $AdS_2$ boundary and the gravity physics near the horizon.

We hope to come back to some of these issues in the near future.

A. Physical charge units

In this appendix we explain the normalization of physical charges adopted in the
text. Electric charge units do not depend on the coupling constant \( g \), therefore we can restrict ourselves to the ungauged limit \( g = 0 \). The five and four-dimensional supergravities studied here can be embedded into compactifications of type II supergravities on \( T^5 \) and \( T^6 \) respectively. The black hole solutions in this limit reduce to the well known 3- and 4-charge black hole solutions of the maximal supergravities. Here we normalize our charges in such a way as to match the electric charge units coming from black holes built out of branes in string theory. The formulas in this appendix follow the notations and conventions in [66]. We refer the reader to this reference for further details and a complete list of references on the subject.

**Newton constant**

\[
G_d = \frac{G_{10}}{(2\pi)^{10-d} V_{10-d}}, \quad G_{10} = 8\pi^6 g_s^2 \ell_s^8 ,
\]

with string length \( \ell_s = \sqrt{\alpha'} \), string coupling constant \( g_s \), and the volume \( V_{10-d} \) of the compactification manifold.

**4-charge black hole**

The Einstein metric of a 4-charge black hole in \( d = 4 \) dimensions can be written as

\[
ds^2 = -(H_1 H_2 H_3 H_4)^{-\frac{1}{2}} dT^2 + (H_1 H_2 H_3 H_4)^{\frac{1}{2}} (dr^2 + r^2 d\Omega_2) ,
\]

\[
H_i = 1 + \frac{c_i N_i}{r} ,
\]

with integers \( N_i \) counting the number of brane constituents and some constants \( c_i \) parametrizing the brane tension. In the near horizon \( r \to 0 \), the black hole geometry becomes

\[
ds^2 = -(c N_1 N_2 N_3 N_4)^{-\frac{1}{2}} r^2 dT^2 + (c N_1 N_2 N_3 N_4)^{\frac{1}{2}} \left( \frac{dr^2}{r^2} + (c N_1 N_2 N_3 N_4)^{\frac{1}{2}} d\Omega_2 \right) ,
\]

with

\[
c = c_1 c_2 c_3 c_4 = \frac{g_s^4 \ell_s^{16}}{16 V_6^2} = 4 G_4^2 .
\]

Notice that although \( c_i \) depends on the type of brane constituent and on the string model, \( c \) is a \( U \)-duality invariant quantity that depends only on \( G_4 \).

After a rescaling of \( dT \) the metric (A.3) can be put into our standard \( AdS_2 \times S^2 \) form (2.4) with

\[
v_1 = v_2 = \sqrt{c N_1 N_2 N_3 N_4} = 2 G_4 \sqrt{N_1 N_2 N_3 N_4} .
\]

Taking \( G_4 = \frac{1}{8} \) and comparing (A.3) with (2.13), one finds agreement with the identification \( q_i = N_i \), i.e. the \( q_i \) are integers. It is important to note that \( G_4 \) can be reabsorbed by a simultaneous rescaling of \( q_i \) and \( S_{BH} \). Therefore the \( G_4 \) dependence in the main text can be restored by sending

\[
q_i \to (8 G_4) q_i , \quad S_{BH} \to (8 G_4) S_{BH} .
\]

Clearly, the \( q_i \)’s defined in this way will not be integers.
3-charge black hole

The Einstein metric of a 3-charge black hole in \( d = 5 \) dimensions can be written as

\[
ds^2 = -(H_1 H_2 H_3)^{-\frac{2}{3}} dT^2 + (H_1 H_2 H_3)^{\frac{1}{3}} (dR^2 + R^2 d\Omega_3), \quad H_i = 1 + \frac{c_i N_i}{R^2}. \tag{A.7}
\]

In the near horizon \( r = R^2 \to 0 \), the black hole geometry becomes

\[
ds^2 = -(c N_1 N_2 N_3)^{-\frac{1}{3}} r^2 dT^2 + (c N_1 N_2 N_3)^{\frac{1}{3}} \frac{dr^2}{4r^2} + (c N_1 N_2 N_3)^{\frac{1}{3}} d\Omega_3, \tag{A.8}
\]

with

\[
c = c_1 c_2 c_3 = \frac{g_s^4 \ell_s^{16}}{V_6^2} = \left( \frac{4G_5}{\pi} \right)^2. \tag{A.9}
\]

Again \( c \) is a \( U \)-duality invariant quantity depending only on \( G_5 \).

After a rescaling of \( dT \) the metric (A.8) can be put into the standard \( AdS_2 \times S^3 \) form (B.4) with

\[
v_2 = 4v_1 = (c N_1 N_2 N_3)^{\frac{1}{3}} = \left( \frac{4G_5}{\pi} \right)^{\frac{2}{3}} (N_1 N_2 N_3)^{\frac{1}{3}}. \tag{A.10}
\]

Taking \( G_5 = \frac{\pi}{4} \) and comparing (A.10) with (B.4), one finds agreement with the identification \( q_i = N_i \), i.e. the \( q_i \) are integers.

It is important to note that \( G_5 \) can be reabsorbed by a simultaneous rescaling of \( q_i \) and \( S_{BH} \). Therefore the \( G_5 \) dependence in the main text can be restored by sending

\[
q_i \to \left( \frac{4G_5}{\pi} \right) q_i, \quad S_{BH} \to \left( \frac{4G_5}{\pi} \right) S_{BH}. \tag{A.11}
\]

Clearly the \( q_i \)’s defined in this way will not be integers.

B. Black holes at \( T = 0 \)

In this Appendix we show that the \( AdS_2 \times S^{d-2} \) geometries derived in the text agree with those coming by taking the zero temperature limit of the most general non-extremal black hole solutions in \( d = 4, 5 \) dimensions. For simplicity we focus on the static case. We refer the reader to [51] for details and references on the AdS black hole solutions quoted in this Appendix.
$d = 4$ case

The general non-extremal and static asymptotically AdS black hole solution of $U(1)^4$ gauged supergravity in $d = 4$ can be written as$^5$:

$$\begin{align*}
    ds_4^2 &= H^{-2} f \, dt^2 + H^2 \left( f^{-1} \, dr^2 + r^2 \, d\Omega_2 \right), \\
    X_I &= \frac{H_I}{H}, \quad F^I = dH_I^{-1} \coth \beta_i dt,
\end{align*}$$

with

$$f = 1 - \frac{m}{r} + 4 g^2 r^2 H^4, \quad H^4 = H_1 H_2 H_3 H_4, \quad H_I = 1 + \frac{m \sinh^2 \beta_i}{r}. \quad (B.2)$$

The parameters $\beta_i$ and $m$ parametrize the electric charges and mass of the black hole. For a generic choice of $m$ the black hole has two horizons at $r_{\pm}$ given by the zeros of $f$. The two horizons coincide when $r_0 = r_+ = r_-$, i.e. when both $f$ and its first derivative vanish at $r = r_0$:

$$f(r_0) = f'(r_0) = 0. \quad (B.3)$$

Denoting

$$\frac{1}{2} \mu_I = r_0 H_I(r_0), \quad (B.4)$$

$$\gamma_1 = \sum_I \mu_I, \quad \gamma_2 = \sum_{i<j} \mu_i \mu_j, \quad \gamma_3 = \sum_{i<j<k} \mu_i \mu_j \mu_k, \quad \gamma_4 = \mu_1 \mu_2 \mu_3 \mu_4,$$

equations (B.3) can be solved for $m$ and $r_0$ in terms of $\mu_I$:

$$m = g \sqrt{\gamma_4 + \frac{1}{4} g^2 \gamma_3^2}, \quad r_0 = \frac{1}{2} m - \frac{1}{4} g^2 \gamma_3. \quad (B.5)$$

The temperature of the black hole is zero for this choice and the horizon geometry takes the $AdS_2 \times S^2$ form with

$$v_1 = \frac{1}{2} H(r_0)^2 \frac{f''(r_0)^{-1}}{1 + g^2 \gamma_2}, \quad v_2 = r_0^2 H(r_0)^2 = \frac{1}{4} \sqrt{\gamma_4}, \quad (B.6)$$

in precise agreement with (2.11).

$d = 5$ case

The general non-extremal and static asymptotically AdS black hole solution of $U(1)^3$ gauged supergravity in $d = 5$ dimensions can be written as$^6$:

$$\begin{align*}
    ds_4^2 &= H^{-2} f \, dt^2 + H^2 \left( f^{-1} \, dr^2 + r^2 \, d\Omega_2 \right), \\
    X_I &= \frac{H_I}{H}, \quad F^I = dH_I^{-1} \coth \beta_i dt,
\end{align*}$$

$^5$The $X_I$’s here are the inverse of the $X_i$’s used in [51]

$^6$The $X_I$’s here are the inverse of the $X_i$’s used in [51]
with
\[ f = 1 - \frac{m}{r^2} + g^2 r^2 H^3, \quad H^3 = H_1 H_2 H_3, \quad H_I = 1 + \frac{m \sinh^2 \beta_i}{r^2} \quad \text{(B.8)} \]

The parameters \( \beta_i \) and \( m \) parametrize the electric charges and mass of the black hole. For a generic choice of \( m \) the black hole has two horizons at \( r_{\pm} \) given by the two positive zeros of \( f \). The two horizons coincide \( r_0 = r_{\pm} \) when parameters are chosen such that both \( f \) and its first derivative vanish at the horizon:
\[ f(r_0) = f'(r_0) = 0 \quad \text{(B.9)} \]

Denoting
\[ \mu_I = r_0^2 H_I(r_0), \quad \gamma_1 = \sum_I \mu_I, \quad \gamma_2 = \sum_{I<J} \mu_I \mu_J, \quad \gamma_3 = \mu_1 \mu_2 \mu_3, \]

equations (B.9) can be solved for \( m \) and \( r_0 \) in terms of \( \mu_I \):
\[ m = g \sqrt{4 \gamma_3 + g^2 \gamma_2^2}, \quad r_0^2 = \frac{1}{2} m - \frac{1}{2} g^2 \gamma_2 \quad \text{(B.10)} \]

The temperature of the black hole is zero for this choice and the horizon geometry takes the \( AdS_2 \times S^3 \) form with:
\[ v_1 = \frac{1}{2} r_0^4 H(r_0) f''(r_0)^{-1} = \frac{1}{4} \frac{1}{\gamma_3}, \quad v_1 = \frac{1}{2} r_0^2 H(r_0) = \gamma_3 \quad \text{(B.11)} \]
in agreement with (B.10).
