*Corresponding author

The experiment was conducted during the year 2017-18 at the instructional farm of Department of Plantation Crops and Processing, Faculty of Horticulture, Uttar Banga Krishi Vishwavidyalaya, West Bengal. The study was aimed to evaluate the effect of graded level application of boron and potassium and their interaction on under developed nuts, shed nuts and split nuts of terai region of West Bengal. The experiment was carried out in a 2.7×2.7 m spaced 12 year old planted with cv. Mohitnagar and laid out in factorial RBD having 12 treatments replicated 4 times with 4 different level of boron viz., B\(_0\), B\(_1\), B\(_2\) and B\(_3\) at 0g, 25g, 50g and sprayed with 4% Na\(_2\)B\(_4\)O\(_7\) solution along with 3 different level of potassium (K\(_2\)O) viz., K\(_1\), K\(_2\) and K\(_3\) at 70 g, 140 g, 210 g of K\(_2\)O per palm respectively to the bunches at 2\(^{nd}\), 4\(^{th}\) and 6\(^{th}\) months respectively per palm at nut development stage at regular intervals. Soil and nut samples are collected from 10 equidistant spots and 10 different palms respectively where as leaf sample is collected from the 4\(^{th}\) index leaf (Ravi Bhat and Sujatha, 2014) from 10 equidistant palms for analysis before and after application of treatments. The results revealed that graded level application of boron and potassium shows that at higher level of boron(B\(_2\)) shows increased potassium content in the soil and nut where as at (B1) the potassium content of the leaf showed highest and at (K3) the potassium content of the soil and nut showed highest potassium and at K2 level the potassium content of leaf is gradually increased (mg/kg) and their interaction effect shows that, higher level combination of both boron and potassium(B\(_2\)-K\(_3\)) shows higher potassium content in the soil and nut (mg/kg) and also 0 level of boron and highest level of potassium showed increased potassium content in the leaf (B\(_0\)-K\(_3\)) and also at B\(_3\)K\(_2\) and B\(_2\)-K\(_2\) level of interaction the yield parameters like (fresh kernel weight and dry kernel weight) shows significant effect.

Introduction

The Areca nut is the fruit of the areca palm (*Areca catechu*) popularly known as betelnut belong to family arecaceae which grows in much of the Tropical pacific (Melanasia and Micronesia), South East Asia and South Africa. It is mainly chewed with the betel leaves, lime, with or without tobacco. The value added form of consumption is by way of pan masala and scented supari. The nut has got some medicinal and neutracritical properties. It is health activator, mouth freshner and has digestive properties. Areca nut can be used for the following purposes like masaj powder, soaps and shampoos, cosmetics, antihelmintic and anti-diabetic, areca wine making, areca soft drink, ayurvedic type of thamboola for chewing purpose, ulcer healing combination, hair oil and dyes, food colours and skin ointments (Prakash, 2010).

Soil fertility is one of the important factors controlling the crop yield; soil related limitations affecting the crop productivity including nutritional disorders can be determined by evaluating the fertility status of soils. Soil testing provides the information about the nutrient availability of the soil upon which the fertilizer recommendation for maximizing crop yield is made.

Under developed nuts are obtained may be because of lack of better pollination and also due to lack of irrigation and also may be due to lack of nutrient availability and competition among the developing nuts causing barrier for good nut development.

Nut shedding may occur due to some abiotic stresses like rainfall, wind etc. and also shedding may occur due to nutrient imbalance especially. It is calculated by substracting from the number of fruits reaches its ripening stage to the number of fruits set initially. Nut splitting is one of the physiological disorder rather than physiological disease, it is characterized by the cracking fruits known as ‘Anduadakke roga’ in kannada, the disease is known as ‘Achikeeral’ in kerala. This is abnormally seen in patches in individual gardens and is common in young plants, it is caused due to nutrient deficiencies due to low potassium availability (Bhat and Sujatha, 2014).

Boron and Potassium nutrients plays a vital role in the growth and development of arecanut palm where all palms are potassium lovers, required in larger quantity for the development of nuts etc., hence it has to be supplied to the plants in the adequate quantity, both excess supply of minerals and limited supply of nutrients leads to different problems. Due to nutrient deficiency in *Terai* region soil the plantation under this region are showing greater extent of potassium and boron deficiency which directly effect on nut development which is leading to nut fall, which ultimately reduces the yield of the crop.

Materials and Methods

The experiment was carried out during 2017-18 at the Instructional Plots of the Department of Plantation Crops and Processing, Uttar Banga Krishi Viswavidyalaya, West Bengal. Physico-chemical properties of the soil analysed by standard methods were soil texture- sandy loam, pH - 5.45 (Jackson, 1973), electrical conductivity - 0.06 dsm-1 (Jackson, 1973), available N - 159. 62 kg/ha (Alkaline KMnO₄ method, Subbiah and Asija, 1956), available P - 23.15 kg/ha (Acid extractable method, Bray and Kurtz, 1945), available K – 145.3 kg/ha (1N ammonium acetate method, Jackson, 1967), and available B – 1.77 mg/kg (Hot water extractable as proposed by Berger and Truog (1939). The experiment was laid out in Factorial Randomised Block Design with 12 treatments
replicated 4 times with 4 different level of boron viz., B₀, B₁, B₂ and B₃ at 0g, 25g, 50g and sprayed with 4% Na₂B₄O₇ solution along with 3 different level of potassium (K₂O) viz K₁, K₂ and K₃ at 70 g, 140 g, 210 g of K₂O per palm respectively to the bunches at 2nd, 4th and 6th months respectively per palm at nut development stage at regular intervals. The sample were collected from base of each palm as separate treatment according to the replication and maintained separately for analysis. In the process, the bulk soil was reduced to 1 kg by following the quartering method. This 1 kg soil sample constituted the composite soil sample. The composite soil samples were then air dried, passed through a 2 mm sieve and stored in clean dry cloth bags with adequate descriptions in attached paper labels. All relevant information and identification marks as required were also recorded. These composite soil samples were analysed in the laboratory for the required soil characteristics and properties and some of the parameters like pH (Jackson, 1973), electrical conductivity (Jackson, 1973), available N (Alkaline KMnO₄ method, Subbiah and Asija, 1956), available P (Acid extractable method, Bray and Kurtz, 1945), available (1N ammonium acetate method, Jackson, 1967), and available B (Hot water extractable as proposed by Berger and Truog (1939) has been analysed and also Leaf samples were collected from the 4th index leaf (Bhat and Sujatha, 2014) from 10 equidistant palms for analysis before application of the fertilizer and after completion of the experiment from each palm as per the treatment, 4 samples were collected from each treatment and the bulking of sample and kept separately for analysis and then determination of boron and potassium content in the leaf sample were done.

Fertilizer are applied in basins around the palm dug to a depth of 15-20cm and 0.75-1.0 m radius from the base of the palm and after the application to the basins were thoroughly mixed with the soil and covered with the top soil. The fertilizer application as stated was followed with light irrigation (Nathanael, 1967 and Dew Saliva, 1968). The initial soil samples 0-15 cm and 15-30 cm depth were collected randomly throughout the experimental plots before commencement of application of fertilizers mentioned in the experimental details. The soil samples were drawn from the selected from a Dutch Auger (Make: AIC Agro-Industries Private Ltd, Kolkata) as initial sample and later as final sample after the completion of experiment. The collected leaf samples were brought to the laboratory and washed immediately with tap water and then rinsed with 0.1 N HCl. The washed and rinsed samples were dried under shade followed by oven drying at a temperature of 65±5 °C so as to reduce the chemical and biochemical changes to the minimum. The oven dried samples were powdered and stored in butter paper bags for chemical analysis. In the same way nut samples were collected after oven drying the dehusked arecanut, the kernel was dried.
separately in the oven after separating husk and kernel and then the kernel was grinded, powdered again oven dried and it was kept separately according to the treatment with its replication and proceeded for analysis for both leaf and nut samples of both boron and potassium content has been analysed using Azomethin- H method and wet digestion method by using tri-acid respectively.

**Results and Discussion**

**Effect of boron and potassium and their interaction on number of underdeveloped nuts, shed nuts and split nuts during the course of nut development per palm**

Under developed nuts are obtained may be because of lack of better pollination and also due to lack of irrigation and also may be due to lack of nutrient availability and competition among the developing nuts causing barrier for good nut development.

As per the data obtained from the analysis showed a significant variation with regard to under developed nuts per palm) i.e., zero level boron application resulted significantly higher underdeveloped nuts (12.33) and B₃ shows significantly lower level of under developed nuts may be direct spraying of boron in bunch at lower level of soil and plant boron but higher than critical level 25-55 mg/kg (Bhat and Sujatha, 2014) played an important role in pollination and consequent nut development and as per the different graded level of potassic fertilizers K₁ (7.17) showed higher underdeveloped nuts and K₃ showed lower (5.50) under developed nuts might be due to antagonistic role of boron and potassium at higher level. The interaction effect of both boron and potassium effect together at different graded levels also resulted significant variation. The treatment B₀K₂ (15.33) showed higher underdeveloped nuts followed by B₀K₃ (13.33) and B₁K₁.

But all the treatments when applied at bunch at 2 months interval irrespective of potassium application resulted significantly lower under developed.

**Effect of boron and potassium on number of Shed nuts during the course of experiment per palm**

Nut shedding may occur due to some abiotic stresses like rainfall, wind etc. and also shedding may occur due to nutrient imbalance especially. It is calculated by subtracting from the number of fruits reaches its ripening stage to the number of fruits set initially.

As per the application of boron, data revealed that B₀ at zero level of application shows maximum shedding nut (140.11) which as statistically at par with B₁ and B₃ level of boron application, so it shows boron plays important role in nut shedding and it corrected by boron application at different levels as mentioned in the experiment, by the same way B₂ level shows significantly lower (77.56) shedding of nuts and at different level of potassium application showed that K₁ (141.17) (Table 1; Fig. 1) shows significantly higher shed nuts and K₂ level resulted significantly lower shed nut (66.25). The combined effect of both B and K application data revealed that B₀K₃ showed significantly higher shedding of nuts (199.33) followed by B₁K₁ (181.00) (Table 2) (Fig. 2) and B₁K₃ (176.33) which might be due to nutrient imbalance at that level but B₂K₂ level shows significantly lower shedding of nuts (28.00) due to moderate uptake of boron (171.167 mg/kg) (Fig. 2) and potassium (3388.20 mg/kg) by the plants and reached equilibrium.
Effect of boron and potassium application on number of Split nuts during the course of experiment per palm

Nut splitting is one of the physiological disorder rather than physiological disease, it is characterized by the cracking fruits known as ‘Anduadakke roga’ in kannada, the disease is known as ‘Achikeeral’ in Kerala. This is abnormally seen in patches in individual gardens and is common in young plants, it is caused due to nutrient deficiencies due to low potassium availability (Bhat and Sujatha, 2014).

Table.1 The 12 different treatment combinations were as follows

| Treatment | Under developed nuts/palm | Shed nut during the course of nut development/palm | Split nut during the course of development/palm |
|-----------|---------------------------|---------------------------------------------------|--------------------------------------------------|
| T1: B0K1  | 0 g borax/palm (0g B) + 70 g K2O/palm |                                   |                                                 |
| T2: B0K2  | 0 g borax/palm (0g B) + 140 g K2O/palm  |                                   |                                                 |
| T3: B0K3  | 0 g borax/palm (0g B) + 210 g K2O/palm  |                                   |                                                 |
| T4: B1K1  | 25 g borax/palm(2.63g B) + 70 g K2O/palm  |                                   |                                                 |
| T5: B1K2  | 25 g borax/palm (2.63g B) + 140 g K2O/palm  |                                   |                                                 |
| T6: B1K3  | 25 g borax/palm (2.63g B) + 210 g K2O/palm  |                                   |                                                 |
| T7: B2K1  | 50 g borax/palm (5.25g B) + 70 g K2O/palm |                                   |                                                 |
| T8: B2K2  | 50 g borax/palm (5.25g B) + 140 g K2O/palm  |                                   |                                                 |
| T9: B2K3  | 50 g borax/palm (5.25g B) + 210 g K2O/palm |                                   |                                                 |
| T10: B3K1 | Spray 0.4% Na2B4O7 + 70 g K2O/palm |                                   |                                                 |
| T11: B3K2 | Spray 0.4% Na2B4O7 + 140 g K2O/palm |                                   |                                                 |
| T12: B3K3 | Spray 0.4% Na2B4O7 + 210 g K2O/palm |                                   |                                                 |

Table.2 Effect of boron and potassium on number of underdeveloped nuts, shed nuts and split nuts during the course of nut development per palm

| Treatment | Under developed nuts/palm | Shed nut during the course of nut development/palm | Split nut during the course of development/palm |

**Fig.1** Effect of boron and potassium application on number of underdeveloped nuts, shed nuts and split nuts during the course of nut development per palm

![Graph showing the effect of boron and potassium application on nut development](image-url)
Mehandale et al., (1999) also reported to reduce nut splitting with the application of spray at 0.2% concentration to the bunches. As per the data obtained from the analysis showed that B₂ resulted significantly higher split nuts (3.55) compared to B₀ and B₁ level and B₃ (0.66) (Table 1) (Fig. 1) shows significantly lower split nuts which might be due to at higher concentration of boron at experimental soil and additional application resulted boron toxicity as reported by and at different graded levels of potash fertilizers reveal that K₃ shows significantly higher split nut (3.33) (Fig. 1) and K₁ significantly lower split nut (0.58) (Table 1 and Fig. 1).

The interaction effect of both fertilizer like boron and potassium at different level shows that B₂K₃ (7.66) (Fig. 2) showed significantly higher split nuts and followed by B₁K₃ (3.33) (Fig. 2). In the treatment combination B₂K₃, both the nutrients fails to establish an equilibrium at higher concentration of boron at the experimental soil and it had been reflected in the potassium content of the leaf (1634.73 mg/kg) though both the nutrients were applied at higher dose and B₀K₃ (2.33) (Table 2; Fig 2) but at B₀K₁,B₀K₂ and B₃K₃ level of application, it does not shows any split nuts, sufficient level of boron in soil favoured the role of potassium and leading to a good result. From the experiment we can conclude that the graded levels of boron and potassium and their interaction indicated that the number of underdeveloped nuts per palm decreased significantly with the increase rate of application of both the nutrients and the combination effect of bunch spraying with moderate application of potassium recorded significantly lowest number of underdeveloped nuts may be due to antagonistic role of boron and potassium at higher level. Shedding of the immature nuts per palm was decreased with increased soil application of boron apart from bunch spraying, and intermediate dose of potassium (K₂) recorded the lowest shed nuts per palm, while production of splitted nuts per palm responded differently bunch spraying of boron and decreased application of potassium leads
to lower split nuts, it may be due to because of antagonistic effect, soil status in that terai region and accumulation of leached nutrients in the soil. At higher level of both boron and lower level of potassium recorded significantly lowest split nuts per palm. Under developed nuts and shedding nut population can be decreased by increased application of boron and intermediate application of potassium where as split nut rate has decreased with increased application of boron and decreased application of potassium content to the soil which may be due to presence of soil condition and raining before and after and while collecting information may be linked up with the parameter. Sufficient level of boron in soil favoured the role of potassium and leading to a good result.
