**Experimental Procedure**

General Considerations. All reagents were obtained from commercial vendors and used without purification. \((1R,2R)\)\(-\)\(1,2\)\-diaminocyclohexane was purchased from SigmaAldrich. \(1,3,5\)\-triformylbenzene was purchased from Combi-Blocks. Dichloromethane (DCM) was obtained as needed from a solvent drying system.

**Synthesis of CC3β**

The cage was synthesized using a strategy adapted from previous reports. A 1L Schlenk flask equipped with \(N_2\) line and stir bar was charged with 2.5914 g (22.69 mmol) \((1R,2R)\)\(-\)\(1,2\)\-diaminocyclohexane, 2.4706 g (15.24 mmol) triformylbenzene, and 750 mL freshly distilled DCM. The vessel was capped with a septum and the atmosphere was purged with \(N_2\) for 1 hour. The purge needle was removed and the clear pale-yellow solution was allowed to stir under an \(N_2\) atmosphere for 3 days. After synthesis, three methods were explored for storage. A portion of the solution was evacuated to dryness, yielding an off-white crumbly powder which was stored inside a glove box. A portion of the solution was transferred to a smaller vessel and purged with \(N_2\) to dryness to allow for an air-free slow evaporation, yielding a flaky off-white solid which was stored inside a glove box. The remainder was preserved in solution under \(N_2\) until needed.

**High-Pressure Methane Procedure**

High-pressure isotherms were collected on a Sieverts’ apparatus (PCT-Pro-2000 from Hy-Energy Scientific Instruments) using ultrahigh purity gases. Total adsorption was calculated using NIST Thermochemical Properties of \(CH_4\) and the pore volume of each material, as determined via 77 K \(N_2\) adsorption experiments.

**Density Measurement**

High-pressure methane gravimetric uptake was converted to volumetric uptake using three densities: the crystallographic density of the CC3β cage, the tap density of the activated cage, and a solvent-compacted density. The tap density of the activated cage was obtained by filling a tared, graduated glass tube with cage and gently tapping it until it was sufficiently settled. Density was calculated using the mass of the cage in the tube and the volume measured by from the graduation marks. Solvent-compacted density was calculated by adding DCM to the top of the tap density sample and letting it evaporate under flowing nitrogen. After complete activation of the sample using a Micromeritics Smart VacPrep, the volume was again determined from the graduation marks, yielding the density.
Powder X-ray Diffraction Data
Powder X-ray diffraction patterns were taken at room temperature on a Rigaku MiniFlex powder diffractometer.

Figure S1. Powder X-ray diffraction patterns for the as-synthesized and activated cage as compared to the simulated pattern of the CC3β polymorph.¹

Nuclear Magnetic Resonance Spectra

Figure S2. NMR Spectrum of the activated cage.
Thermogravimetric Analysis
Thermogravimetric analysis (TGA) and TGA-combustion were performed using a TA Q5000 SA. For the TGA, the sample was heated to 600 °C at a ramp rate of 2 °C/min under a flow of N\(_2\). For the TGA-combustion, the sample was heated to 150 °C with a ramp rate of 10 °C/min under a flow of N\(_2\) to remove all solvent from the sample, and was subsequently cooled to 100 °C. The gas was switched from N\(_2\) to O\(_2\) and the sample was heated to 600 °C with a ramp rate of 3 °C/min to combust the sample.

![Figure S3](image-url)

**Figure S3.** TGA (top) and TGA-Combustion (bottom) plots for the cage. The blue trace represents weight percent. The red trace represents temperature. The black line denotes the change in gas from N\(_2\) to O\(_2\).
Gas Adsorption Procedure
Low-pressure 77 K N₂ gas adsorption measurements were obtained with a Micromeritics Tristar gas adsorption analyzer. Both flow and vacuum degassing were investigated. For flow activated samples, the Tristar tubes were purged with N₂ on a Micromeritics SmartPrep system after being heated in an oven to remove water. After cooling, the tubes were sealed without exposure to air, weighed, and brought into the glove box. The cage was loaded into the tube, sealed, and degassed at room temperature overnight on the SmartPrep before measuring. For the vacuum activated samples, the Tristar tubes were evacuated on a Smart VacPrep system after being heated in an oven to remove water. After cooling and evacuating the air, the sealed tube was backfilled with N₂ and weighed. The loading and activation procedure was the same as for the flow activated samples, using the Smart VacPrep instead of the SmartPrep. Once fully activated, the tubes were weighed to determine an accurate mass of the samples. N₂ adsorption isotherm measurements were surveyed from 25 °C to 300 °C in increments of 25 °C. Once maximum surface area was achieved, new samples were then loaded and heated to their optimal temperature. Surface areas were measured via N₂ isotherm in a 77 K liquid nitrogen bath and calculated using the Micromeritics software. All other isotherms were obtained using a Micromeritics 3Flex, submerging the sample in a temperature controlled bath.

Isotherm Fitting
The adsorption isotherms were fit with single- or dual-site Langmuir-Freundlich model (Eq. 1), where \( n \) is the absolute amount adsorbed in mmol/g, \( P \) is the pressure in bar, \( q_{sat,1} \) is the saturation capacity in mmol/g, \( b_1 \) is the Langmuir parameter in bar\(^{-1}\), and \( v_1 \) is the Freundlich parameter for two sites, 1 and 2. The parameters used to fit the adsorption isotherms can be found in Tables S1-S9. Plots of the adsorption isotherms along with their fits are presented in Figures S7-S15.

\[
n = \frac{q_{sat,1}b_1v_1}{1+b_1Pv_1} + \frac{q_{sat,2}b_2v_2}{1+b_2Pv_2}
\]  

The isosteric heats of adsorption, \(-Q_{st}\), were calculated through the use of the Clausius-Clapeyron equation (Eq. 2) for each gas using the single- or dual-site Langmuir-Freundlich fits for each material at 298 K, 308 K, and 318 K. \( P \) represents pressure, \( n \) is the amount adsorbed, \( T \) is the temperature, \( R \) is the universal gas constant, and \( C \) is a constant. The slope of \((\ln P)_n\) as a function of \(1/T\) was used to obtain the isosteric heats of adsorption for each gas, shown in Figure S16 and Table S10.

\[
\ln P = -\frac{Q_{st}}{R} \left(\frac{1}{T}\right) + C
\]
N₂ Full Isotherms

Figure S5. N₂ uptake of the flow activated cage at optimal degas temperature. Solid stars denote adsorption and outlines denote desorption.
