A Study of Maternal Mortality in a Tertiary Care Teaching Hospital in Andhra Pradesh, South India

Savitri Somasekhar¹, Priscilla Bhaskara²

¹,²Department of Obstetrics and Gynaecology, Government General Hospital, Anantapur, Andhra Pradesh, India.

ABSTRACT

BACKGROUND
Maternal mortality is measure of adequacy of health care system and socio-economic status of the country. Globally every day thousands of women die of pregnancy related causes, majority in developing countries. It has adverse effect on family, society and country.

METHODS
In this retrospective study maternal deaths occurring in the Government General Hospital, Anantapur, from Jan 2018 to Oct 2021 were analysed using medical case records.

RESULTS
In present study, a total of 48 maternal deaths, with MMR of 142.35 per one lakh live births were analysed. Maximum number of deaths occurred in age group between 20 to 25 years. 68.75% were uneducated and 31.25 % had literacy just above 10th class. A majority, 95.8% belonged to low socioeconomic group. Most cases were unbooked, 91.69%. There were 81.25% of referred cases and 18.75% in house cases. G2 G3, primi formed the majority of study population. Major cause of MMR was due to direct cause, 77%. Hypertensive disorders in pregnancy accounted for 35%, obstetric haemorrhage in 25% followed by pulmonary embolism/AF embolism, 10.4%. Indirect causes accounted for 23%. Anaemia accounted for majority of indirect cause, 72.9%.

CONCLUSIONS
Majority of maternal deaths occurred in patients from rural areas, unbooked uneducated patients and from poor socioeconomic status. Hypertensive disorders of pregnancy and obstetric haemorrhage are major direct causes of maternal deaths, anaemia being the commonest indirect cause. Access to antenatal care and skilled care during child birth play a vital role in reducing maternal mortality.

KEY WORDS
Maternal Mortality, Obstetric Haemorrhage, Hypertensive Disorders of Pregnancy, Anaemia.
BACKGROUND

Proper antenatal care and skilled timely care during child birth are key factors in preventing most of maternal deaths. Health care solutions to prevent and manage complications related to maternal mortality are well known. Maternal mortality continues to remain unacceptably high. Globally, lankhs of women die of pregnancy related causes, majority from developing countries. Maternal mortality is a measure of adequacy of health care system and socioeconomic status of the country. WHO defines maternal mortality as the death of any pregnant woman or within 42 days of termination of pregnancy, disregarding duration or site of pregnancy, from any cause related to or aggravated by pregnancy but not from accidental or incidental cause.

MMR - maternal death per one lakh live births - International definition of maternal mortality ratio.

In 2017, 295000 deaths among women were noted during pregnancy and after childbirth. The vast majority of these deaths (94%) occurred in low resource settings & most could have been prevented. Sub-Saharan Africa and Southern Asia together contributed to 86% (2,54,000) of the estimated global maternal deaths in the year 2017.

Sub-Saharan Africa alone contributed to roughly 2/3 (1,96,000) of maternal deaths while Southern Asia nearly one fifth (58,000) of deaths. Greatest overall reduction in MMR was achieved by Southern Asia between 2000 and 2017 A decline of nearly 60% - from an MMR of 384 down to 157.

In 2017, MMR was 462 per one lakh live births in low-income countries as compared to 11 per one lakh live births in high income countries. In many parts of the world a large number of maternal deaths indirectly reflect inequalities that exist in accessing to quality health services which in return highlights the gap between rich and poor.

In order to improve the maternal health indicators, the government of India has implemented many initiatives. Much progress has been made in ending preventable maternal deaths in past two decades. MMR of India for the period of 2016-2018 as per latest report of national sample registration system (SRS) data is 113/1,00,000 live births, declining by 17 points from 130/1,00,000 live births in 2014-2016. Focus on quality and coverage of health services through public health initiatives under National Rural Health Mission have contributed to this decline in maternal deaths.

Most of the complications which develop during pregnancy are potentially preventable and treatable. Some complications may antedate pregnancy which deteriorate during antenatal period especially if not managed as part of woman’s care. Major complications that account for nearly 75% of all deaths are obstetric haemorrhage, hypertensive disorders of pregnancy – preeclampsia & eclampsia, sepsis, unsafe abortions & anaemia. Access to antenatal care, early diagnosis of anaemia & preeclampsia, safe abortion practices, early interventions to prevent & treat postpartum haemorrhage, availability of skilled health professional, institutional deliveries – all these may contribute to life and death for the mother. Main factors which deny adequate health care to pregnant women are ignorance, poverty, lack of transport facilities, poor quality services and cultural practices.

METHODS

This hospital based retrospective study was done in Department of Obstetrics and Gynaecology at Government General Hospital affiliated to GMC (GGH/GMS), Anantapur, Andhra Pradesh. The study was carried out after obtaining approval from Institutional Ethical Committee from January 2018 to October 2021.

Study Tools & Techniques

Medical case records of all maternal deaths occurring in the Government General Hospital, Anantapur from Jan 2018 to Oct 2021 were analysed. All cases of maternal mortality were documented in the maternal death review forms with complete information. Various variables- age, residence, parity, antenatal booking, timing of death, time interval between admission and death, referral status and cause of death were collected from medical records department of hospital and maternal death review forms, were analysed.

Exclusion Criteria

Brought dead cases and deaths due to suicide, homicide and covid related causes were excluded from the study. WHO defines maternal mortality as the death of any pregnant woman or within 42 days of termination of pregnancy, disregarding duration or site of pregnancy, from any cause related to or aggravated by pregnancy but not from accidental or incidental cause. International formula for MMR is maternal death per 1 lakh live births.

Statistical Analysis

Data collected was analysed using Microsoft Excel sheet version 2010. Results were analysed by using ratio, percentage and proportion.

RESULTS

During the study period of 46 months there were 48 maternal deaths giving MMR of 142.35 per one lakh live births = 48x1,00,000/33.719.81.25% of cases were referred from (CHCS, PHC & private hospitals) towns and villages around Anantapur. 18.75% of cases were internal cases of our hospital. Tabulation of results done based on age, mode of delivery, parity index, gestation, socio economic condition, education status and cause of death.

| Year | Total No. of Live Births | Maternal Deaths | MMR |
|------|--------------------------|-----------------|-----|
| 2018 | 9101                     | 7               | 76.24% |
| 2019 | 9272                     | 13              | 140.2% |
| 2020 | 7843                     | 13              | 165.75% |
| 2021 (Jan-Oct) | 7423 | 15 | 282.07% |

Table 1. Year Wise Distribution of MMR

| Age Group | No. of Deaths | Percentage |
|-----------|---------------|------------|
| 20-25 yrs. | 26            | 54%        |
| 25-30 yrs. | 12            | 25%        |
| < 20 yrs.  | 2             | 4.1%       |
| >30 yrs.   | 8             | 16.6%      |

Table 2. Age Wise Distribution of MMR
There were 40% vaginal births and 50% LSCS and 4% deaths due to ectopic pregnancy, 4% mothers undelivered and 2% deaths due to miscarriage in this study. 68.75% were uneducated and 31.25% had literacy just above 10th class. A majority 95.8% belonged to low socioeconomic group and 4.1% were from middle income group. Most cases were unbooked (91.69%) and only 8.3% were booked cases, 3 or more AN visits. 37.5% of cases were less than 37 weeks of pregnancy and 29.1% belonged to term gestation at the time of death. Peripartum C-section was done in moribund cases to save foetus. There were 81.25% of referred cases and 18.75% in house cases.

| Parity Index | No. of Deaths | Percentage |
|--------------|---------------|------------|
| Primipara    | 15            | 31.25%     |
| G2 G3        | 27            | 56.25%     |
| G4 & >       | 6             | 12.5%      |

Table 3. Parity Index and MMR

| Cause of Death | No. of Deaths | Percentage |
|----------------|---------------|------------|
| Direct cause   | 37            | 77%        |
| Indirect cause | 11            | 23%        |

Table 4. Cause of Death and MMR

| Cause of Death | Number of Deaths | Percentage |
|----------------|------------------|------------|
| Anaemia (moderate + gross) | 35 | 72.9% |
| Jaundice complications in pregnancy | 1 | 2.08% |
| Bronchopneumonia | 3 | 6.25% |
| Meningoencephalitis | 1 | 2.08% |
| Diabetic ketoacidosis | 2 | 4.16% |

Table 5. Indirect Causes of MMR

Many of direct causes of maternal deaths are potentially preventable and treatable. Maternal mortality is a key health indicator. Obstetric haemorrhage (especially after child birth), sepsis in pregnancy & puerperium, preeclampsia & eclampsia, unsafe abortions – all these contribute to a big chunk of maternal deaths.1,3,5

For the period of 2016-18, Maternal Mortality Ratio (MMR) of India is 113/100,000 live births, as declared by national registration system data, declining by 17 points, from 130/100,000 live births in 2014-16. According to this, 2,500 additional mothers saved yearly in 2018 as compared to 2016. Total estimated annual maternal deaths show a decline from 33800 maternal deaths in 2016 to 26437 deaths in 2018.3

Present study included 48 maternal deaths, with MMR of 142.35 per one lakh live births. This is higher than national average of 113/100,000 live births. Andhra Pradesh with a birth-rate of 21.3% has MMR of 154 (2003). Women in reproductive age suffer from disability & death, mainly due to complications during pregnancy and child birth. Poverty, unhygienic living, illiteracy, infections & unregulated fertility together synergise and result in health problems of mother & new-born. At the same time, average infrastructure and less effective public health services are also responsible for the existing poor obstetric care.6

In the present study, higher MMR was noted in 2021(202.07%), 2020(165.75%) This may be due to more high-risk referrals in Covid pandemic period and less availability of peripheral healthcare facility. Referral cases accounted for majority 81.25% cases, in-hospital cases being only 18.75%. 68.75% were uneducated and 31.25% had literacy up to 10th class. A majority of 95.8% belonged to low socioeconomic group and 4.1% were from middle class. Most cases were unbooked contributing to 91.69% and only 8.3% were booked cases (3 or more AN visits). Unbooked cases in poor health state coming from rural and peripheral areas contributed to higher maternal mortality ratio in present study. Ours being a tertiary care centre located in rural area, receiving complicated referral cases in moribund state. 81.25% of cases were referred from (CHCS, PHC & private hospitals) towns and villages around Anantapur.

Majority of deaths occurred in age group between 20 to 25 years in our study. G2 G3 formed a larger segment of 27 cases (56.25%), followed by primipara 15 cases (31.25%). Literature comparison shows maximum maternal deaths in the age group between 20 to 24 years, in multiparous women, women from rural areas, unbooked patients, low socioeconomic status and illiterate women.7,8,9

Direct causes were responsible for 77% of maternal deaths. Hypertensive disorders of pregnancy, 35%, was the leading direct cause of death followed by obstetric haemorrhage in 25% and pulmonary embolism/AF embolism in 10.4% of cases.

Direct cause was responsible for 77% of maternal deaths. Hypertensive disorders of pregnancy, 35%, was the leading direct cause of death followed by obstetric haemorrhage in 25% and pulmonary embolism/AF embolism in 10.4% of cases.

Table 6. Direct Causes of MMR

Table 5. Direct Causes of MMR

| Cause of Death | Number of Deaths | Percentage |
|----------------|------------------|------------|
| PIH, preeclampsia and eclampsia (HDP) | 17 | 35% |
| Obstetric haemorrhage (APH & PPH) | 12 | 25% |
| Sepsis | 3 | 6.25% |
| Pulmonary embolism/AF embolism | 5 | 10.4% |
| Ectopic pregnancy | 2 | 4% |

Table 7. Cause of Death and MMR

Indirect causes were responsible for 23% of maternal deaths. Moderate (<9 gm) and severe anaemia (<7 gm) was responsible for death in majority of cases. Gross of Hb < 7gm was observed in 18 cases accounting for 37.5% of cases. Anaemia (moderate + gross) accounted for majority, 72.9%, of indirect causes of MMR followed by bronchopneumonia and diabetic ketoacidosis.

**DISCUSSION**

Many of direct causes of maternal deaths are potentially preventable and treatable. Maternal mortality is a key health indicator. Obstetric haemorrhage (especially after child birth), sepsis in pregnancy & puerperium, preeclampsia & eclampsia, unsafe abortions – all these contribute to a big chunk of maternal deaths.1,3,5

For the period of 2016-18, Maternal Mortality Ratio (MMR) of India is 113/100,000 live births, as declared by national registration system data, declining by 17 points, from 130/100,000 live births in 2014-16. According to this, 2,500 additional mothers saved yearly in 2018 as compared to 2016. Total estimated annual maternal deaths show a decline from 33800 maternal deaths in 2016 to 26437 deaths in 2018.3

Present study included 48 maternal deaths, with MMR of 142.35 per one lakh live births. This is higher than national average of 113/100,000 live births. Andhra Pradesh with a birth-rate of 21.3% has MMR of 154 (2003). Women in reproductive age suffer from disability & death, mainly due to complications during pregnancy and child birth. Poverty, unhygienic living, illiteracy, infections & unregulated fertility together synergise and result in health problems of mother & new-born. At the same time, average infrastructure and less effective public health services are also responsible for the existing poor obstetric care.6

In the present study, higher MMR was noted in 2021(202.07%), 2020(165.75%) This may be due to more high-risk referrals in Covid pandemic period and less availability of peripheral healthcare facility. Referral cases accounted for majority 81.25% cases, in-hospital cases being only 18.75%. 68.75% were uneducated and 31.25% had literacy up to 10th class. A majority of 95.8% belonged to low socioeconomic group and 4.1% were from middle class. Most cases were unbooked contributing to 91.69% and only 8.3% were booked cases (3 or more AN visits). Unbooked cases in poor health state coming from rural and peripheral areas contributed to higher maternal mortality ratio in present study. Ours being a tertiary care centre located in rural area, receiving complicated referral cases in moribund state. 81.25% of cases were referred from (CHCS, PHC & private hospitals) towns and villages around Anantapur.

Majority of deaths occurred in age group between 20 to 25 years in our study. G2 G3 formed a larger segment of 27 cases (56.25%), followed by primipara 15 cases (31.25%). Literature comparison shows maximum maternal deaths in the age group between 20 to 24 years, in multiparous women, women from rural areas, unbooked patients, low socioeconomic status and illiterate women.7,8,9

Direct causes were responsible for 77% of maternal deaths and indirect causes for 23%. Hypertensive disorders of pregnancy (PIH, Preeclampsia and eclampsia) were leading causes of death followed by obstetric haemorrhage (APH, PPH, 3rd stage bleeding). Obstetric haemorrhage accounts for 25% of cases in our study and can be well tackled by universally adopting to active management of third stage of labour by giving IM oxytocin. With wide availability and usage of misoprostol tablets and carboprost injections there is reduction in maternal deaths due to postpartum haemorrhage in recent times. Direct causes related to maternal deaths accounted for 72.5% in a study by Bhaskar et al. Haemorrhage (26.66%), eclampsia (26.66%), and sepsis (18.33%) was the major direct causes of maternal deaths, whereas only one maternal death (0.83%) was due to obstructed labor. Singla et al. reported similar higher incidence of HDPs followed by obstetric haemorrhage and sepsis.10

Direct causes contributed to 23% of maternal deaths. Moderate (<9 gm) and severe anaemia (<7 gm) were responsible for death in majority of cases. Anaemic mothers tolerated haemorrhage poorly and succumbed to death. Gross Hb < 7gm was observed in 18 cases accounting for 37.5% of
Maternal deaths are common in poor, unbooked, uneducated patients hailing from rural area. Hypertensive disorders of pregnancy, obstetric haemorrhage are major direct causes of maternal deaths, anaemia being the commonest indirect cause. Quality antenatal care in pregnancy and skilled timely care during childbirth are need of the hour to achieve the goals set to decrease maternal mortality ratio.
