Additional index words. herbicide, runoff, recycled water, substrate, Lavandula pedunculata, Buxus microphylla

Abstract. Ronstar® and Rout® are two of the most common and effective preemergent herbicides used by the nursery industry. However, there is some uncertainty as to what happens to the chemicals in nurseries that are recycling their runoff water. The fate of the chemicals has been studied in two nurseries that are completely dependent on recycled water. Negligible amounts were found in the recycled irrigation water. Most of each herbicide remained where it was applied, either close to the top in the substrate, or on the surface of the growing area, for periods of =4 months. Five months after application, <10% of oryzalin remained vs. =30% of the oxyfluorfen and oxadiazon. Less residue was produced if oxadiazon was applied when the pots were packed together after potting up, compared to application to spaced pots in the standing area. These herbicides are of low mammalian toxicity, and the main hazard is from contamination on the standing area after application, and from the top layer of substrate. To minimize any risk, we recommend that the herbicides be applied before the plants are spaced out on the growing area, and that staff handling the pots take suitable precautions, and in particular avoid inserting their unprotected hands into the top of the mix. Chemical names used: 2-tert-butyl-4-(2,4-dichloro-5-isopropoxyphenyl)-3-N-1,3,4-oxadiazolin-5-one (oxadiazon); 4-(dipropylamino)-3,5-dinitrobenzenesulphonamide (oryzalin); 2-chloro-1-(3-ethoxy-4-nitrophenoxy)-4-(trichloromethyl)benzene (oxyfluorfen); tritium-labelled [N-(4-chloro-2-fluoro-S-(propargyloxy)-phenyl]-3,4,5,6-tetrahydrophthalimide [3H]THP.

Oxadiazon (Ronstar®; Rhone-Poulenc Rural Australia, Sydney, Australia) and oryzalin plus oxyfluorfen (Rout®; Grace-Sierra Australia, Sydney, Australia) are very widely used in the nursery industry for preemergence weed control (e.g., Gilliam et al., 1990). They control a wide range of weeds, and have damaging effects on few established plants. However, in cold weather they can be phytotoxic, especially with repeated applications, if they are applied falls between pots when it is applied to a nursery situation, 20% to 80% of herbicide enter the soil or water environment. However, in the nursery situation, 20% to 80% of herbicide enters the soil or water environment. However, there is some uncertainty as to what happens to the chemicals in nurseries that are recycling their runoff water. The fate of the chemicals has been studied in two nurseries that are completely dependent on recycled water. Negligible amounts were found in the recycled irrigation water. Most of each herbicide remained where it was applied, either close to the top in the substrate, or on the surface of the growing area, for periods of =4 months. Five months after application, <10% of oryzalin remained vs. =30% of the oxyfluorfen and oxadiazon. Less residue was produced if oxadiazon was applied when the pots were packed together after potting up, compared to application to spaced pots in the standing area. These herbicides are of low mammalian toxicity, and the main hazard is from contamination on the standing area after application, and from the top layer of substrate. To minimize any risk, we recommend that the herbicides be applied before the plants are spaced out on the growing area, and that staff handling the pots take suitable precautions, and in particular avoid inserting their unprotected hands into the top of the mix. Chemical names used: 2-tert-butyl-4-(2,4-dichloro-5-isopropoxyphenyl)-3-N-1,3,4-oxadiazolin-5-one (oxadiazon); 4-(dipropylamino)-3,5-dinitrobenzenesulphonamide (oryzalin); 2-chloro-1-(3-ethoxy-4-nitrophenoxy)-4-(trichloromethyl)benzene (oxyfluorfen); tritium-labelled [N-(4-chloro-2-fluoro-S-(propargyloxy)-phenyl]-3,4,5,6-tetrahydrophthalimide [3H]THP.

The objective of this work was to determine the concentration and location of oxadiazon, oryzalin, and oxyfluorfen residues, and the changes with time after application in nurseries that were recycling runoff water.

Materials and Methods

The trials were carried out on two nurseries located 45 km northwest of Sydney, Australia (lat. 33°37’S, long. 151°04’E). Both are completely dependent on rain and recycled water, with runoff collected in dams at the nursery, and no runoff beyond the nursery except in the most exceptional circumstances.

Plants. Both nurseries were growing a wide range of species, all treated with granular preemergent herbicide at the time of planting out in the autumn. The nursery where the oxadiazon study was carried out grows a range of herbaceous perennials. The studies reported here were on a block planted with lavender (Lavandula pedunculata ‘Purple Crown’) in 140-mm (1.4-L) pots. The substrate was a proprietary mix from Debco, Tyabb, Australia, containing pine bark and copra peat, with the addition of 25% perlite and 1 kg·m−2 of Green Jacket slow release fertilizer (Debco, Tyabb, Australia). The studies on oryzalin plus oxyfluorfen were at a nursery growing a range of trees and shrubs in 140-mm (1.4-L) pots with a substrate of medium-coarse and fine pine bark and 10% sand, containing 4 kg·m−2 Green Jacket slow-release fertilizer. The trials were on a block planted to Buxus microphylla ‘Japonica’.

At both nurseries, the plants were overhead-irrigated and stood on a growing area of subsoil, covered by a layer of gravel =10 cm deep, which was covered in turn by a layer of weed mat. The plant pots were spaced out on the weed mat =70 mm apart.
Application of oryzalin plus oxyfluorfen. No preemergent herbicide was applied between Aug. 1997 and 27 Mar. 1998. On 28 Mar. and 16 Nov. 1998, 10 g·m⁻² of Rout® (0.2 g oxyfluorfen plus 0.1 g oryzalin) was applied. Samples were taken for analysis on 21 Apr., 20 May, 23 June, 21 Aug., 25 Sept., and 3 Dec. 1998 (24, 53, 87, 147, and 181 d after the first application and 17 d after the second application). Samples were taken of the irrigation, dam, and runoff collection basin water or silt.

Effect of application method on oxadiazon levels. No oxadiazon was applied to the experimental site between 11 July 1996 and 16 Apr. 1997. Samples were taken on 24 Oct. 1996 and 8 Apr. 1997 to establish the background concentrations. Two methods of application were used. First, oxadiazon was applied to the pots once plants had been potted up, set out in the growing area, and watered in. This is the normal method used at the nursery. This was compared with applying the herbicide to the pots as soon as they had been potted up, on trolleys, before being moved to the growing area and set out and watered in. In both cases, the rate of application of Rout® was 20 g·m⁻² (0.4 g oxadiazon).

The normal cycle of production in the nursery where the oxadiazon trial was conducted is propagation in the late summer (January and February), and potting up in March/April, with most sales in the spring (September/October). The starting date for the trial was 16 Apr. 1997. The samples were taken the day after treatment and then every 6 weeks until the plants were sold in late September.

Temperature, rainfall and evaporation. Data are given in Table 1. Irrigation at both nurseries was by overhead sprinklers, 5–6 mm given twice per day, but varied at the manager’s discretion. Rainfall and mean daily minimum temperatures over the months April to September were relatively low in 1997, and relatively high in 1998.

Sampling. At both nurseries, sampling procedures were as follows. 1) Samples of surface water (dam) and free-run irrigation water were taken, collected from three or four positions, and mixed to give a final volume of 1 L. 2) The substrate from two or four pots, chosen at random, was well mixed, and a 100-g subsample taken. In some pots, the substrate from each pot was split into the top third, the middle third, and the bottom third before sampling, with the large plant roots from the top third taken as a separate sample. 3) The runoff collection basin collected the water and runoff from the full block of plants, ~2000 pots. The sample consisted of the mud in the collection basin in the oxadiazon trial, and of the water in the collection basin in the oxadiazon plus oxyfluorfen trial. 4) Samples of ~100 g were taken from several areas of the weed mat to give a total sampling area of ~1 m². The main component of these samples was substrate fines washed out of the pots. 5) The samples taken from beneath the weed mat were a mixture from two to four locations, and contained a mixture of silt (from earthworm activity) and gravel.

Analyses for presence and concentration of the three chemicals were carried out by Australian Government Analytical Laboratories (AGAL) at Pymble, NSW, Australia. For the analysis of oryzalin and/or oxyfluorfen, the water samples were processed by liquid–liquid extraction, and the soil and substrate samples were processed by solid–liquid extraction.

The liquid–liquid extraction method used 400 mL of sample in a 1-L separatory funnel. The pH was adjusted to 11 using sodium hydroxide and the aqueous phase extracted with 50 mL of dichloromethane (DCM); the bottom layer (DCM) was transferred into a TurboVap tube (Zymark Corp., Hopkinton, Ma.). The previous step was repeated before the DCM in the TurboVap tube was concentrated down and the solvent exchanged to a TurboVap tube (Zymark Corp., Hopkinton, Ma.). The previous step was repeated before the DCM in the TurboVap tube was concentrated down and the solvent exchanged to a TurboVap tube (Zymark Corp., Hopkinton, Ma.). The previous step was repeated before the DCM in the TurboVap tube was concentrated down and the solvent exchanged to a TurboVap tube (Zymark Corp., Hopkinton, Ma.). The previous step was repeated before the DCM in the TurboVap tube was concentrated down and the solvent exchanged to a TurboVap tube (Zymark Corp., Hopkinton, Ma.).

The solid–liquid extraction consisted of weighing out a 10-g sample into a jar. About 1 g of anhydrous, granular, sodium carbonate was added to adjust the pH to 11. Fifty milliliters of 3 hexane : 2 acetone (v/v) was added, mixed vigorously for 2 h, and then allowed to stand. The acetone/hexane layer was then passed through a column of anhydrous sodium sulfate to remove any remaining water. The extract was then analysed using the same gas chromatograph described above.

For the analysis of oxadiazon, 10-g soil and substrate samples were extracted with 50 mL of 2 hexane : 1 acetone (v/v). The extract was run directly on a dual column (DB1701 and DB5) gas chromatograph with dual ECD. Water samples (200–300 mL) were extracted with dichloromethane, which was concentrated to a volume 1% of the original sample size (e.g., 200 mL sample to 2 mL), then analyzed using the same gas chromatograph conditions as for soils. This is the AGAL in-house method, which is based on U.S. Environmental Protection Agency methods. Recovery rates (mean ± 95% confidence intervals) for water were 94 ± 37%, for substrate 119 ± 43%, and for soil 110 ± 19%. Detection limits for oxyfluorfen and oxadiazon were 0.1 mg·kg⁻¹ in soil and substrate, and 0.1 µg·L⁻¹ in water. Detection limits for oryzalin were 1.0 mg·kg⁻¹ in soil and substrate, and 1.0 µg·L⁻¹ in water.

Results

Oryzalin plus oxyfluorfen. Although the initial runoff water from pots after application of Rout® contained 43 mg·L⁻¹ oryzalin and 4.9 mg·L⁻¹ oxyfluorfen, levels measured in the runoff collection basin water were always below 1 µg·L⁻¹ for both herbicides, except for a value of 1.4 µg·L⁻¹ oryzalin on 21 Apr. (Table 2). Levels in dam water, irrigation water and the dam silt were always below the detectable limit.

Relatively high concentrations of residues were found on the weed mat (Fig. 1), peaking at 130 mg·kg⁻¹ oxyfluorfen on 3 Dec., 17 d after the application on 16 Nov., and, in general, declining with time during the 5 months after the first application. Only very low (oxyfluorfen on 3 Dec.) or nondetectable amounts were found below the weed mat.

The other location of much of the oryzalin and oxyfluorfen was in the substrate in which the plants were growing (Table 3). Oryzalin was found only in the top third of the mixture. Concentrations declined with time until reapplication in mid-November. Oxyfluorfen was more persistent in the substrate. As with oryzalin, the highest concentration was found in the mix near the top of the pot, but appreciable herbicide was also found in the middle and bottom of the pot. Concentrations declined with time, but to a far smaller extent than those of oryzalin, with about a third still present 5 months after application compared to <10% of the oryzalin.

Oxadiazon trial. The background levels of oxadiazon found before the experiment started are given in Table 4. Even 9 months after the last application, the chemical was still present in trace amounts in the irrigation water, and in the soil below the weedmat. Thus, oxadiazon is a persistent chemical in the nursery environment.

On the day after application, the amount of oxadiazon in the standing area following application on the trailers was ≈1% of that following application to the spaced-out plants (Table 5). Treating the plants before placement on the growing area greatly reduced the amount of chemical likely to reach the irrigation water. For example, the runoff collection basin below the site also had <1% of the amount of chemical found with on-site application. Even 5 months later, the latter collection basin had only 10% of the concentration of the on-site treatment. The effect of the two application methods on the levels in recycled water could not be determined, but this also should be far less with application before spacing out.

The highest oxadiazon concentration was found on the surface of the weed mat following application to spaced-out pots. The concentration of oxadiazon on the weed mat fell with time following treatment on the growing area. There were no clear trends with time at the other locations, or in the other treatment, except perhaps for an increase in concentration in the run-off collection basin below the block where the pots were treated on the trailer.

The data in Table 5 indicates the average concentration of oxadiazon in the pot. However, most of the chemical is in the top third of the substrate (Table 6). Note the higher concentration at the bottom of pots treated on the standing area. This will have entered the bottom of the pot by capillary uptake. The results indicate the immobility and stability of the compound.

Discussion

In agreement with data from previous studies (Barrett and Lavy, 1984; Keese et al., 1994), oryzalin was rapidly released from the pots, whereas both oxyfluorfen and oxadiazon were more strongly retained. To appreciate the significance of the concentrations of the residues, they must be compared with concentrations shown to be hazardous (Table 7).

Toxic levels for plants. In the irrigation water: Glaze et al. (1987) found damage to aucuba (Aucuba japonica Thunb.), azalea ([Rhododendron (AZ)], liriope [Liriope muscari (Decne) L.H. Bailey], pampas grass [Cortaderia selloana (Schult. & Schult. f.) Asch. & Graebn.], Japanese black pine ([Pinus thunbergiana Franco]), and red tip photinia ([Photinia 'Fraseri' Dress] plants from oxadiazon applied in a liquid formulation at rates of 8.8 mg·L⁻¹ and above. We found 0.16 µg·L⁻¹ in the irrigation water, which is over four orders of magnitude less than the toxic level for the sensitive plants used by Glaze and coworkers. The results for oryzalin and

<sup>*</sup> 9 months after last application.
oxyfluorfen were similar, with damage to sensitive species at 1 mg·L⁻¹ (Ahrens, 1994); concentrations in the irrigation water were always below the detection limits of 1 µg·L⁻¹ (oryzalin) or 0.1 µg·L⁻¹ (oxyfluorfen), which is <0.1% of the toxic level. Thus, our results indicate that the risk to the nursery plants from recycled pre-emergent herbicide in the irrigation water is essentially zero. This is in agreement with the studies of Camper et al. (1994) on oryzalin and oxyfluorfen conducted in South Carolina.

The main hazard to established plants is directly from the applied herbicide; however there is an extensive literature on what species are sensitive. Note that the herbicides are still present at an effective concentration in the upper layers of the substrate when the plants are sold, so that for a limited time they could continue acting as preemergent herbicides in customer’s gardens.

Environmental risk. The environmental risk to wild species from the recycled water appears to be low. Toxic levels for one of the more sensitive species, rainbow trout (Oncorhynchus mykiss Walbaum) are given in Table 7. Peak concentrations found in the runoff collection basin water, which were much higher than in the dam water, were still only 0.1% of the reported LC50 levels. Nevertheless, the LC50 concentrations are lethal with 96 h exposure. Information on the effects of persistent exposure of wildlife to lower concentrations of the herbicides would be valuable.

Our results reinforce those of earlier studies indicating that oxadiazon and oxyfluorfen are highly stable and relatively immobile in the substrate. They are potentially dangerous, since they are so persistent. Oxadiazon is considered a probable human carcinogen (Group B), classified as B2,—i.e., there is evidence of carcinogenicity from animal studies, with inadequate or no epidemiological data for humans. However, according to Von Burg (1994), there is no risk when used according to directions. Oxyfluorfen is classed as Group C, an even lower risk class (Ahrens, 1994). The major hazards from using these chemicals are probably to nursery staff, particularly from the concentrations of oxadiazon and oxyfluorfen that persist on the growing area from in situ application, and in the upper layers of the substrate. Clearly, to minimize the risk, application should only be made to plants that are close-packed (pot to pot), rather than spread out on the growing area. Both methods involve some exposure of nursery staff to the chemicals, but the second method uses far less oxadiazon, since the pots are pot-to-pot (pots occupy 90% of space), whereas in the standing area they were spaced half a pot apart, or 210-mm center to center (pots occupy 40% of space). This will also minimize the amount of preemergent herbicide used. To minimize exposure, nursery staff should wear protective clothing, including suitable footwear and especially gloves, not only when applying the herbicide, but also when handling (i.e., spacing out, and preparing for sale) the pots.

### Table 5. Oxadiazon concentrations [mg·kg⁻¹ (soil or plant substrate) or µg·L⁻¹ (water)] following application of Ronstar® on 16 Apr. 1997 to Lavandula pedunculata 'Purple Crown' plants in 140-mm pots.

| Soil in runoff collection basin | 0.013 | 0.14 | 0.09 | 0.63 |
| Plant substrate     | 31.0 | 8.7 | 26.0 | x<sup>+</sup> |
| Growing area        | Substrate on weed mat | 5200.0                   | 3200.0 | 1500.0 | 230.0 |
| Soil under weed mat | 3.2 | 8.8 | 5.8 | 4.2 |
| Soil in runoff collection basin | 5.6 | 9.0 | 9.0 | 6.0 |
| Plant substrate     | 18.0 | 24.0 | 18.0 | x<sup>+</sup> |

<sup>x</sup><sup>+</sup> = not measured.

### Table 6. Oxadiazon concentration (mg·kg⁻¹) in pot plants ready for sale. The herbicide had been applied 9 months earlier, to pots either compacted together pot-to-pot on the trailer, or spaced out on the growing area.

| Site of application | Roots from top third of substrate | Substrate | Top third | Middle third | Bottom third |
|---------------------|----------------------------------|-----------|-----------|--------------|--------------|
| Trailer             | 2.7                              | 150       | 1.6       | 16.5         |
| Growing area        | 3.5                              | 110       | 2.4       | 0.8          |

### Table 7. Toxic levels of the three herbicides used.

| Species | Oryzalin (mg·L⁻¹) | Oxyfluorfen (mg·L⁻¹) | Oxadiazon (mg·L⁻¹) | Source<sup>a</sup> |
|---------|------------------|----------------------|-------------------|-------------------|
| Plants (postemergent application in irrigation water) | 1<sup>°</sup> | 1<sup>°</sup> | 8.8<sup>°</sup> | Bhandary et al., 1997; Glaze et al., 1987 |
| Rats—LD<sub>50</sub> (mg·kg⁻¹ body wt) | >5000 | >5000 | 12,000.0<sup>°</sup> | Ambrosi and Richard, 1985 |
| —chronic toxicity (mg·kg⁻¹ body wt·d⁻¹) | >14 | 2 | 20–500.0<sup>°</sup> | Richert et al., 1996 |
| —cancer (mg·kg⁻¹ of diet) | >12 | 150 | 1000.0<sup>°</sup> | Von Burg, 1994 |
| Tadpoles 48 h LC<sub>50</sub> | 2.5<sup>°</sup> | 2.5<sup>°</sup> | 2.5<sup>°</sup> | Von Burg, 1994 |
| Rainbow trout 96 h LC<sub>50</sub> | 3.26 | 0.4 | 1–9.0 | Von Burg, 1994 |
