Abstract

A new notion of a dual Poisson-presymplectic pair is introduced and its properties are examined. The procedure of Dirac reduction of Poisson operators onto submanifolds proposed by Dirac is in this paper embedded in a geometric procedure of reduction of dual Poisson-presymplectic pairs. The method presented generalizes those used by Marsden and Ratiu for reductions of Poisson manifolds. Two examples are given.

AMS 2000 Subject Classification: 70H45, 53D17, 58A10, 70G45

1 Introduction

In [1] P.A.M. Dirac introduced a method of reducing a given Poisson bracket onto a submanifold \( S \) given by some constraints \( \varphi \). A geometric meaning of this reduction procedure has been investigated in [2] and also in [3]. In this paper we complete this picture by its "dual" part by developing a theory of Marsden-Ratiu type reduction of presymplectic 2-forms \( \Omega \) that are (in a sense developed below) dual to a given Poisson operator \( \Pi \).

This paper is organized as follows. In this section we recall some basic notions from Poisson and presymplectic geometry. In Section 2 we introduce and discuss a central for this paper notion of a dual Poisson-presymplectic (dual P-p) pair. We also examine some basic properties of P-p pairs. In Section 3 we present a geometric reduction procedure of such a pairs to any submanifold that
its tangent bundle contains the kernel of the presymplectic form that enters our P-p pair. This is the main section of this paper. We conclude the article by Section 4 containing two examples.

Given a manifold $\mathcal{M}$, a Poisson operator $\Pi$ on $\mathcal{M}$ is a bivector, $\Pi \in \Lambda^2(\mathcal{M})$ (degenerate in general) such that its Schouten bracket with itself vanishes. A function $c : \mathcal{M} \to \mathbb{R}$ is called Casimir function of the Poisson operator $\Pi$ if for any function $F : \mathcal{M} \to \mathbb{R}$ we have $\{F,c\}_\Pi = 0$ (or, equivalently, if $\Pi dc = 0$). A vector field $X_f$ related to a function $f$ by relation

$$X_f = \Pi df$$

is called a Hamiltonian vector field with respect to the Poisson operator $\Pi$. If $X$ is any vector field on $\mathcal{M}$ that is Hamiltonian with respect to $\Pi$ then $L_X\Pi = 0$, where $L_X$ is the Lie-derivative operator in the direction $X$.

Further, a presymplectic form $\Omega$ on $\mathcal{M}$ is a 2-form that is closed (degenerate in general). The kernel of any presymplectic form of constant rank is always integrable. A vector field $X_f$ related to a function $f$ by relation

$$\Omega X_f = df$$

is called an inverse Hamiltonian vector field with respect to the presymplectic operator $\Omega$. For a closed two-form $\Omega$ if $\Omega(Y) = 0$ for some vector field $Y$ on $\mathcal{M}$ then $L_Y\Omega = 0$.

Notice that when $\Pi$ is nondegenerate one can always define $\Omega = \Pi^{-1}$, and then the equations (1) and (2) are equivalent and a vector field that is Hamiltonian with respect to $\Pi$ is simultaneously inverse Hamiltonian with respect to $\Omega$. In the degenerate case we encounter problems. Firstly, one can not define $\Omega$ as the inverse of $\Pi$. Secondly, for a degenerate $\Pi$ the equation (1) defines a Hamiltonian vector field for any function $f$ (as in the nondegenerate case), while for a degenerate $\Omega$ and arbitrary $f$ there is usually no such vector field $X_f$ that (2) is fulfilled. In other words, equation (2) is valid only for a particular class of functions (contrary to the nondegenerate case). We will try to overcome these difficulties in the next Section. We will constantly assume that our degenerate operators are of constant rank.

## 2 Dual Poisson-presymplectic pairs

In this section we develop and discuss a central for this article notion of a dual Poisson-presymplectic pair.

Consider a smooth manifold $\mathcal{M}$ of dimension $m$ equipped with a pair of antisymmetric operators $\Pi$, $\Omega$.

**Definition 1** A pair of antisymmetric tensor fields $(\Pi, \Omega)$ such that $\Pi : T^*\mathcal{M} \to T\mathcal{M}$ (i.e. $\Pi$ is twice contravariant) and $\Omega : T\mathcal{M} \to T^*\mathcal{M}$ (i.e. $\Omega$ is twice covariant) is called a dual pair if there exists $r$, $0 \leq r \leq m$, functionally independent scalar functions $c_i : \mathcal{M} \to \mathbb{R}$, $i = 1, \ldots, r$ and $r$ linearly independent vector fields $Y_i$, $i = 1, \ldots, r$ such that the following conditions are satisfied:

1. $\{F, c_i\}_\Pi = 0$ for any function $F : \mathcal{M} \to \mathbb{R}$ and any $i = 1, \ldots, r$.
2. $\Omega(Y_i, X) = df$ for any vector field $X$ on $\mathcal{M}$ and any function $f$.

1. $Y_i(c_j) = \delta_{ij}$ for all $i, j = 1, \ldots, r$.

2. The kernel of $\Pi$ is spanned by the differentials $dc_i$, $\ker(\Pi) = \text{Sp}\{dc_i\}_{i=1\ldots r}$.

3. The kernel of $\Omega$ is spanned by the vector fields $Y_i$, $\ker(\Omega) = \text{Sp}\{Y_i\}_{i=1\ldots r}$.

4. The following partition of identity holds on $T\mathcal{M}$

$$I = \Pi\Omega + \sum_{i=1}^{r} Y_i \otimes dc_i$$

where $\otimes$ denotes the tensor product.

We would like to point out that our definition of a dual pair means something different than the definition of a dual pair introduced by A. Weinstein in [6]. Besides, we mostly work with dual pairs consisting of Poisson operators and closed forms (which we call 'dual P-p pairs', see below), so hopefully it will not cause any confusion.

The partition of identity (3) reads on $T^*\mathcal{M}$ as

$$I = \Omega^*\Pi^* + \sum_{i=1}^{r} dc_i \otimes Y_i$$

which due to antisymmetry of $\Pi$ and $\Omega$ yields

$$I = \Omega\Pi + \sum_{i=1}^{r} dc_i \otimes Y_i.$$ (4)

Let us call the foliation of $\mathcal{M}$ associated with the functions $c_i$ by $\mathcal{N}$. That foliation consists of level submanifolds $\mathcal{N}_\nu$ of functions $c_i$, $\mathcal{N}_\nu = \{x \in \mathcal{M} : c_i(x) = \nu_i, i = 1, \ldots, r\}$, $\nu = (\nu_r, \ldots, \nu_1)$. The condition 1 of the above definition implies that the distribution $Y$ spanned by the vector fields $Y_i$ is transversal to the foliation $\mathcal{N}$ i.e. that no vector in $Y$ is ever tangent to the foliation $\mathcal{N}$. Thus, for any $x \in \mathcal{M}$ we have

$$T_x\mathcal{M} = T_x\mathcal{N}_\nu \oplus Y_x, \quad T^*_x\mathcal{M} = T^*_x\mathcal{N}_\nu \oplus Y^*_x$$

where $\mathcal{N}_\nu$ is a submanifold from the foliation $\mathcal{N}$ that passes through $x$, the symbol $\oplus$ denotes the direct sum of the vector spaces, $Y_x$ is the subspace of $T_x\mathcal{M}$ spanned by the vectors $Y_i$ at this point, $T^*_x\mathcal{N}_\nu$ is the annihilator of $Y_x$ and $Y^*_x$ is the annihilator of $T_x\mathcal{N}_\nu$. The condition 2 of the above definition implies that the image $\text{Im}(\Pi)$ is at every point tangent to a level submanifold $\mathcal{N}_\nu$ that passes through this point. Indeed, if $\Pi dc_i = 0$ then for any 1-form $\alpha$ we have, due to the antisymmetry of $\Pi$, that $\langle dc_i, \Pi\alpha \rangle = - \langle \alpha, \Pi dc_i \rangle = 0$ for all $i = 1, \ldots, r$, so that the vector $\Pi\alpha$ is always tangent to $\mathcal{N}$. The condition 3 means that $\text{Im}(\Omega)$ is in every point $x$ contained in $T_x^*\mathcal{N}_\nu$ (again for appropriate $\nu$). Indeed, if $\Omega(Y_i) = 0$ for all $i = 1, \ldots, r$ then for any vector field $V$ we have (due to the antisymmetry of $\Omega$) $\langle \Omega V, Y_i \rangle = - \langle \Omega Y_i, V \rangle = 0$. The condition 4 is the most interesting one: obviously, it describes the degree of degeneracy of our pair. But if we restrict our attention to those dual pairs that consist of a Poisson operator and of a closed 2-form then it has yet another, deeper meaning.
Definition 2 A dual pair \((\Pi, \Omega)\) is called a dual Poisson-presymplectic pair (in short: dual P-p pair) if \(\Pi\) is Poisson and if \(\Omega\) is closed.

Remark 3 In the case where a dual P-p pair has no degeneration \((r = 0)\) we get the usual Poisson-symplectic pair of mutually inverse operators, since \(I = \Pi \Omega\). In the case where \(r = m\) we have full degeneration: \(\Pi = 0\) and \(\Omega = 0\) as then \(Sp\{dc_i\}_{i=1..r} = T^*\mathcal{M}\) and \(Sp\{Y_i\}_{i=1..r} = T\mathcal{M}\). This case will be therefore excluded as non-interesting.

Let \((\Pi, \Omega)\) be a dual P-p pair and let
\[X_f = \Pi df\] (5)
be a Hamiltonian vector field with respect to \(\Pi\). Applying \(\Omega\) to both sides of (5) we get
\[df = \Omega(X_f) + \sum_{i=1}^{r} Y_i(f)dc_i.\] (6)
In that sense \(\Omega\) plays the role of the "inverse" of \(\Pi\). Notice that vector fields that are Hamiltonian with respect to \(\Omega\) are precisely those that are related to functions \(f\) which are annihilated by \(\ker(\Omega)\). For such functions (6) reduces to (2).

Proposition 4 For a dual P-p pair \((\Pi, \Omega)\) the vector fields \(Y_i\) mutually commute: \([Y_i, Y_j] = 0, \ i, j = 1, \ldots, r\).

Proof. Since \(\Omega\) is presymplectic, \(\ker(\Omega)\) is an integrable distribution so that
\[[Y_i, Y_j] = \sum_{k=1}^{r} \phi_{ij}^k Y_k,\]
where \(\phi_{ij}^k\) are some functions on \(\mathcal{M}\). Evaluating this relation on all Casimirs \(c_i\) we immediately find that \(\phi_{ij}^k = 0\) for all \(i, j, k = 1, \ldots, r\). ■

Of course, the vector fields \(Y_i\) and the forms \(dc_i\) in the definition of a dual pair are not unique. For example, we can change the basis in the distribution spanned by \(Y_i\) and compensate it by a change of basis in the distribution spanned by \(dc_i\). We have however the following uniqueness theorem:

Theorem 5 (uniqueness theorem) Suppose that \((\Pi, \Omega)\) and \((\Pi, \Omega')\) are two dual P-p pairs that share the same \(c_i\) and such that \(\ker(\Omega) = \ker(\Omega')\). Then \(\Omega = \Omega'\).

Proof. Since \(\ker(\Omega) = \ker(\Omega')\) then \(Y_i' = \sum_{j=1}^{r} \lambda_{ij} Y_j\) for some functions \(\lambda_{ij}\) such that \(\det(\lambda_{ij}) \neq 0\). Thus
\[\delta_{ij} = Y_i'(c_j) = \sum_{s=1}^{r} \lambda_{is} Y_s(c_j) = \sum_{s=1}^{r} \lambda_{is} \delta_{sj} = \lambda_{ij},\]
so that $Y'_i = Y_i$ for all $i$. Thus, since $I = \Pi \Omega + \sum_{i=1}^r Y_i \otimes dc_i$ and $I = \Pi' \Omega + \sum_{i=1}^r Y_i \otimes dc_i$ we have that $\Pi (\Omega' - \Omega) = 0$ which implies $\Omega' - \Omega = 0$ since the product of two antisymmetric operators is zero only if (at least) one of them is zero.

The question thus arises: what is the actual 'gauge freedom' for a given dual P-p pair? In other words: given a dual P-p pair $(\Pi, \Omega)$ how can we deform $\Omega$ to a new presymplectic form $\Omega'$ so that $(\Pi, \Omega')$ is again dual or how can we deform $\Pi$ to a new Poisson operator $\Pi'$ so that $(\Pi', \Omega)$ is also a dual P-p pair? An example of such a gauge freedom is given below.

**Proposition 6** Let $(\Pi, \Omega)$ be a dual P-p pair as in definitions 1 and 2. Define

$$\Omega' = \Omega + \sum_i df_i \wedge dc_i,$$

where $f_i$ are some real functions on $\mathcal{M}$. Then $(\Pi, \Omega')$ is a dual P-p with $\ker(\Omega') = \text{Sp} \{ Y'_i = Y_i - \Pi df_i \}$ provided that

$$Y_i(f_j) - Y_j(f_i) + \{f_i, f_j\}_\Pi = 0 \text{ for all } i, j. \quad (7)$$

The proof is by direct computation.

Before we consider a gauge freedom for the operator $\Pi$ we prove a useful lemma.

**Lemma 7** Let $(\Pi, \Omega)$ be a dual P-p pair. Then

$$L_{Y_i} \Pi = 0, \quad i = 1, \ldots, r. \quad (8)$$

**Proof.** From the partition of identity and the property $L_{Y_i} \Omega = 0$ we have

$$0 = L_{Y_i} I = (L_{Y_i} \Pi) \Omega + \Pi (L_{Y_i} \Omega) + \sum_{j=1}^r [Y_i, Y_j] \otimes dc_j$$

$$= (L_{Y_i} \Pi) \Omega.$$

On the other hand, from the property $\Pi dc_j = 0$, it follows that

$$0 = L_{Y_i}(\Pi dc_j) = (L_{Y_i} \Pi) dc_j \quad \text{as} \quad L_{Y_i} dc_j = d(\delta_{ij}) = 0.$$  

Thus, from the decomposition 1, for any function $f$ we have

$$(L_{Y_i} \Pi) df = (L_{Y_i} \Pi) \left( \Omega(X_f) + \sum_{i=1}^r Y_i(f) dc_i \right) = 0$$

and arbitrariness of $f$ implies that $L_{Y_i} \Pi = 0$. ■
Proposition 8 Suppose that \((\Pi, \Omega)\) is a dual P-p pair. Suppose that \(K_i, i = 1, \ldots, r\) are vector fields that are Hamiltonian with respect to \(\Pi\) and inverse Hamiltonian with respect to \(\Omega\), i.e.

\[ \Omega(K_i) = dH_i, \quad K_i = \Pi dH_i \]  \(9\)

for some functions \(H_i\) and such that

\[ \Omega(K_i, K_j) = 0 \quad \text{for all } i, j. \]  \(10\)

Then the pair \((\Pi', \Omega)\) with \(\Pi' = \Pi + \sum_{i=1}^{r} Y_i \wedge K_i\) is a dual P-p pair with vector fields \(Y_i\) and Casimirs \(c'_i = c_i + H_i\).

Proof. An easy calculation with the use of partition of identity and the assumptions \(9\) yields

\[ \Pi' \Omega = I - \sum_i Y_i \otimes dc'_i, \]

so that the partition of identity for \((\Pi', \Omega)\) is satisfied. Moreover,

\[ Y_i(H_j) = \langle \Omega K_j, Y_i \rangle = - \langle \Omega Y_i, K_j \rangle = 0 \]

as \(\Omega(Y_i) = 0\), so that

\[ Y_i(c'_j) = Y_i(c_j) + Y_i(H_j) = Y_i(c_j) = \delta_{ij}. \]

Further: \(K_i(c_j) = \langle dc_j, \Pi dH_i \rangle = - \langle dH_i, \Pi dc_j \rangle = 0\) which implies

\[ \Pi' dc'_j = \sum_i \Omega(K_j, K_i) Y_i = 0 \]

due to the assumption \(10\).

One can also show (by using Lemma \(7\)) that the Schouten bracket \([\Pi', \Pi']_S\) vanishes so that \(\Pi'\) is indeed Poisson. ■

Let us now turn our attention to brackets induced on the space \(C_\infty(M)\) of all smooth real valued functions on \(M\).

We know that the Poisson operator \(\Pi\) turns the space \(C_\infty(M)\) of all smooth real valued functions on \(M\) into a Poisson algebra with the Poisson bracket

\[ \{ F, G \}_\Pi = \langle dF, \Pi dG \rangle \]  \(11\)

In the case where \(\Omega\) is a part of a dual P-p pair we can define the above bracket through the action of \(\Omega\) on \(X_F\) and \(X_G\).

Proposition 9 Let \((\Pi, \Omega)\) be a dual P-p pair. Define a new bracket on \(C_\infty(M)\) through

\[ \{ F, G \}_\Omega = \Omega(X_F, X_G), \]

where as usual \(X_F = \Pi dF\) and \(X_G = \Pi dG\). Then \(\{\cdot, \cdot\}_\Omega = \{\cdot, \cdot\}_\Pi\) i.e. both brackets are identical.
Proof. A simple calculation yields
\[
\Omega(X_F, X_G) = \langle \Omega X_F, X_G \rangle = \langle \Omega \Pi dF, \Pi dG \rangle =
\]
\[
= \langle dF, \Pi dG \rangle \sum_i Y_i(F) \langle dc_i, \Pi dG \rangle = \langle dF, \Pi dG \rangle,
\]
as \langle dc_i, \Pi dG \rangle = - \langle dG, \Pi dc_i \rangle = 0. The equality with the asterisk is due to the partition of identity on \( T^*M \).

Let us now present two examples of \( P\)-\( p \) pairs.

Example 10 Consider a manifold \( M \) parametrized locally by coordinates
\[
(q_1, \ldots, q_n, p_1, \ldots, p_n, c_1, \ldots, c_r)
\]
and a pair of operators that in these coordinates have the form
\[
\Pi = \begin{pmatrix}
0 & I_n & 0_{2n \times r} \\
-I_n & 0_n & 0_r \\
0_{r \times 2n} & 0_r & 0_r
\end{pmatrix},
\Omega = \begin{pmatrix}
0 & -I_n & 0_{2n \times r} \\
I_n & 0_n & 0_r \\
0_{r \times 2n} & 0_r & 0_r
\end{pmatrix}
\]
i.e. \( \Pi \) is the canonical Poisson operator with \( r \) Casimirs \( c_i \) while \( \Omega \) is the canonical presymplectic form with the kernel spanned by \( Y_i = \frac{\partial}{\partial c_i} \). Here and in what follows \( I_n \) denotes an \( n \times n \) identity matrix and in general subscripts by a matrix block denote the dimensions of this block. Obviously, \( Y_i(c_j) = \delta_{ij} \).
Moreover, the product \( \Pi \Omega \) has the form
\[
\Pi \Omega = \begin{pmatrix}
I_{2n} & 0_{2n \times r} \\
0_{r \times 2n} & 0_r
\end{pmatrix}
\]
while the tensor product \( \sum_{i=1}^r Y_i \otimes dc_i \) has the form
\[
\sum_{i=1}^r Y_i \otimes dc_i = \begin{pmatrix}
0_{2n} & 0_{2n \times r} \\
0_{r \times 2n} & I_r
\end{pmatrix}
\]
and thus the partition of identity \( ] \) is satisfied. Thus, all the conditions of Definition \( ] \) are satisfied. Notice also that both \( \Pi \) and \( \Omega \) have constant rank \( 2n \).
This simple example will be further developed in Section 4.

We will now present a non-canonical example.

Example 11 In our second example we consider a five dimensional manifold \( M \) parametrized (locally) by coordinates \( (q_1, q_2, p_1, p_2, e) \) and a pair of operators given by
\[
\Pi = \begin{pmatrix}
0 & 0 & 0 & \frac{1}{2}q_1 & p_1 \\
0 & 0 & \frac{1}{2}q_1 & q_2 & p_2 \\
0 & -\frac{1}{2}q_1 & 0 & -\frac{1}{2}p_1 & 0 \\
-\frac{1}{2}q_1 & -q_2 & \frac{1}{2}p_1 & 0 & e \\
-p_1 & -p_2 & 0 & -e & 0
\end{pmatrix}
\]

1
and
\[
\Omega = \begin{bmatrix}
0 & 2p_1 & 4q_p & -2 \frac{1}{q_1} & \frac{1}{2} (p_1 p_2 - q_1 e) \\
-2p_1 & 0 & -2 \frac{1}{q_1} & 0 & -\frac{1}{2} p_1^2 \\
-4q_p & 2 \frac{1}{q_1} & 0 & 0 & \frac{1}{2} q_1 p_2 - q_2 p_1 \\
2 \frac{1}{q_1} & 0 & 0 & 0 & -\frac{1}{2} p_1^2 \\
\frac{1}{2} (q_1 e - p_1 p_2) & \frac{1}{2} p_1^2 & q_2 p_1 & -\frac{1}{2} q_1 p_2 & -\frac{1}{2} q_1 p_1 & 0
\end{bmatrix}
\] (14)

Both these operators have constant rank 4 (generically). It is easy to check that \(\Pi\) is Poisson and that \(\Omega\) is closed. The only (independent) Casimir of \(\Pi\) is given by
\[
c = -\frac{1}{2} q_2 p_1^2 + \frac{1}{2} q_1 p_1 p_2 - \frac{1}{4} e q_1^2,
\] (15)
while the kernel of \(\Omega\) is spanned by the vector field
\[
Y = p_1 \frac{\partial}{\partial q_1} + p_2 \frac{\partial}{\partial q_2} + e \frac{\partial}{\partial p_2} - 4 \frac{\partial}{\partial q_1^2}.
\]

Naturally, \(Y(c) = 1\). The explicit form of the tensor \(Y \otimes dc\) is rather complicated but a direct calculation shows that \(\Pi \Omega + Y \otimes dc = I\). Thus, \((\Pi, \Omega)\) is a dual P-p pair. This example will also be developed later on.

The first example (Example 10) illustrates that the following existence statement must be true.

**Proposition 12** For a given Poisson operator \(\Pi\) of constant rank on \(M\) there always exists (locally) a closed two-form \(\Omega\) such that \((\Pi, \Omega)\) is a dual P-p pair and vice versa, for a given presymplectic form \(\Omega\) of constant rank there always exists a Poisson operator \(\Pi\) such that \((\Pi, \Omega)\) is a dual P-p pair.

**Proof.** Given a Poisson operator \(\Pi\) (a closed two-form \(\Omega\)) it is enough to pass to the Darboux coordinates for \(\Pi\) (\(\Omega\)) and choose \(\Omega\) (\(\Pi\)) as in Example 10.

\[\square\]

### 3 Dirac reduction of Poisson-presymplectic pairs

Consider now a smooth \(m\)-dimensional manifold \(M\) endowed with a dual P-p pair \((\Pi, \Omega)\) as in definitions 1 and 2 and a smooth \(s\)-dimensional foliation \(S\) of \(M\) with the leaves \(S_\nu = \{ x \in M : \varphi_i(x) = \nu_i, \nu_i \in \mathbb{R}, i = 1, \ldots, k \} \) given by \(s\) functionally independent functions \(\varphi_i : M \to \mathbb{R}\). In this section we present a procedure of reducing of the dual P-p pair \((\Pi, \Omega)\) to a dual P-p pair \((\pi_R, \omega_R)\) on any leaf \(S_\nu\) of \(S\) provided that some additional assumptions about relative positions of the foliations \(\mathcal{N}\) and \(S\) hold and that we are in a generic case that will be called Dirac case. This reduction will be similar to ideas developed by J. Marsden and T. Ratiu (see \[2\] and \[3\]).

Let us thus fix a distribution \(Z\) (to be determined later) of constant dimension \(k = m - s\) (that is a smooth collection of \(k\)-dimensional subspaces \(Z_x \subset\)
$T_x\mathcal{M}$ at every point $x$ in $\mathcal{M}$) that is transversal to $\mathcal{S}$ in the sense that no vector field $Z \in \mathcal{Z}$ is at any point tangent to the foliation $\mathcal{S}$. Hence we have

$$T_x\mathcal{M} = T_x\mathcal{S}_\nu \oplus \mathcal{Z}_x$$

for every $x \in \mathcal{S}_\nu$, and similarly

$$T^*_x\mathcal{M} = T^*_x\mathcal{S}_\nu \oplus \mathcal{Z}^*_x$$

where $T^*_x\mathcal{S}$ is the annihilator of $\mathcal{Z}_x$ and $\mathcal{Z}^*_x$ is the annihilator of $T_x\mathcal{S}$. This distributions is assumed to be regular i.e. there exists linearly independent vector fields $Z_i, i = 1, \ldots, k$, such that $\mathcal{Z} = \text{Sp}\{Z_i\}_{i=1,\ldots,k}$. Without loss of generality we can assume that the vector fields $Z_i$ are chosen so that the following normalization condition holds

$$Z_i(\varphi_j) = \delta_{ij}.$$ 

There exists a natural projection $X\|_\nu$ of an arbitrary vector field $X$ on $\mathcal{M}$ along $\mathcal{Z}$ onto the foliation $\mathcal{S}$ given by

$$X\|_\nu = X - \sum_{i=1}^k X(\varphi_i)Z_i,$$

as obviously $X\|_\nu(\varphi_i) = 0$. Similarly, any one-form $\alpha$ can be naturally projected along $\mathcal{Z}$ to a one-form $\alpha\|_\nu$ on $T^*\mathcal{S}$ as follows:

$$\alpha\|_\nu = \alpha - \sum_{i=1}^k \alpha(Z_i)d\varphi_i$$

since $\alpha\|_\nu(Z_i) = 0$. Finally, let us define the vector fields $X_i, i = 1, \ldots, s$ as the Hamiltonian vector fields $X_i = \Pi d\varphi_i$.

**Definition 13** A function $F : \mathcal{M} \to \mathbb{R}$ is invariant with respect to $\mathcal{Z}$ if $L_Z F = Z(F) = 0$ for any $Z \in \mathcal{Z}$.

**Definition 14** A Poisson operator $\Pi$ is invariant with respect to the distribution $\mathcal{Z}$ if $\{F, G\}_\Pi$ is a $\mathcal{Z}$-invariant function for any pair of $\mathcal{Z}$-invariant functions $F$ and $G$. That is, if $L_Z F = L_Z G = 0$ then $L_Z \{F, G\}_\Pi = 0$.

Let us now consider a $\mathcal{Z}$-invariant Poisson operator $\Pi$ and define the following bilinear map:

$$\Pi_D (\alpha, \beta) = \Pi(\alpha\|_\nu, \beta\|_\nu) \text{ for any pair } \alpha, \beta \text{ of one-forms.}$$

This new mapping induces a new bracket for functions on $\mathcal{M}$:

$$\{F, G\}_{\Pi_D} = \Pi_D (dF, dG) = \Pi((dF)\|_\nu, (dG)\|_\nu)$$
and thus it is easy to show that the corresponding bivector $\Pi_D$ has the following form
\[
\Pi_D = \Pi - \sum_i X_i \wedge Z_i + \frac{1}{2} \sum_{i,j} \varphi_{ij} Z_i \wedge Z_j
\]
(18)
which we can treat as a deformation of the original Poisson bivector $\Pi$. Here the functions $\varphi_{ij}$ are defined as
\[
\varphi_{ij} = \{\varphi_i, \varphi_j\}_\Pi = X_j(\varphi_i).
\]
(19)

**Theorem 15** For any $x \in \mathcal{M}$
\[
\Pi_D(\alpha_x) \in T_x\mathcal{S} \quad \text{for any } \alpha_x \in T_x^*\mathcal{M},
\]
i.e. the image of $\Pi_D$ is tangent to the foliation $\mathcal{S}$.

**Proof.** We have to show that $\Pi_D(d\varphi_k) = 0$ for all $k$. According to (18) we have
\[
\Pi_D(d\varphi_k) = X_k - \sum_i \delta_{ik} X_i + \sum_i \varphi_{ki} Z_i + \frac{1}{2} \sum_{i,j} \varphi_{ij} (\delta_{jk} Z_i - \delta_{ik} Z_j) = \\
= \sum_i \varphi_{ki} Z_i + \frac{1}{2} \sum_i \varphi_{ik} Z_i - \frac{1}{2} \sum_j \varphi_{kj} Z_j = 0,
\]
due to skewsymmetry of $\varphi_{ij}$. ■

**Theorem 16** If a Poisson operator $\Pi$ is $\mathcal{Z}$-invariant then the bivector (18) is Poisson.

**Proof.** The operator $\Pi_D$ is obviously antisymmetric and the corresponding bracket $\{\cdot, \cdot\}_{\Pi_D}$ satisfies Lebniz rule. The Jacobi identity for $\{\cdot, \cdot\}_{\Pi_D}$
\[
\{\{F, G\}_{\Pi_D}, H\}_{\Pi_D} + \text{cycl.} = 0
\]
reads due to (17) as
\[
\left( d\left(\left(\langle (dF)_{||}, \Pi (dG)_{||}\rangle\right)_{||}, \Pi (dH)_{||}\right)\right) + \text{cycl.} = 0.
\]
(20)

But due to (16)
\[
\left( d\left(\langle (dF)_{||}, \Pi (dG)_{||}\rangle\right)_{||}\right) = d\left(\langle (dF)_{||}, \Pi (dG)_{||}\rangle\right) - \sum_i Z_i \left(\left(\langle (dF)_{||}, \Pi (dG)_{||}\rangle\right) d\varphi_i, \right)
\]
and in every point $x \in \mathcal{M}$ we have $(dF)_{||}, (dG)_{||} \in T^*\mathcal{S}$ so that
\[
Z_i \left(\left(\langle (dF)_{||}, \Pi (dG)_{||}\rangle\right)_{||}\right) = \left(\langle (dF)_{||}, (L_Z\Pi) (dG)_{||}\rangle\right)_{||} = 0,
\]
and
\[
\left(\langle (dF)_{||}, \Pi (dG)_{||}\rangle\right)_{||} = \left(\langle (dF)_{||}, (L_Z\Pi) (dG)_{||}\rangle\right)_{||} = 0.
\]
the last equality is fulfilled due to the assumed $\mathcal{Z}$-invariance of $\Pi$. Thus, the Jacobi identity (20) reads actually as
\[
\left\langle d\left\langle (dF)_{||}, \Pi (dG)_{||} \right\rangle, \Pi (dH)_{||} \right\rangle + \text{cycl.} = 0,
\]
and is obviously satisfied due to the Jacobi identity for $\Pi$.

Since the deformed operator $\Pi_D$ is Poisson and since the functions $\varphi_i$ are its Casimirs, we can properly restrict $\Pi_D$ to any of its symplectic leaves $S_\nu$, obtaining a reduced Poisson operator $\pi_R$ on every leaf $S_\nu$.

\[
\pi_R \overset{\text{def}}{=} \Pi_D|_{S_\nu}
\]

Up to now the distribution $\mathcal{Z}$ was not fully determined. In the generic case (that we call Dirac case), when all the vector fields $X_i$ are transversal to the foliation $\mathcal{S}$, we can choose the distribution $\mathcal{Z}$ simply as the span of the vector fields $X_i$, $\mathcal{Z} = \text{Sp}\{X_i\}_{i=1,\ldots,k}$. We can now define our vector fields $Z_i$ as a new basis of $\mathcal{Z}$:
\[
Z_i = \sum_{j=1}^k (\varphi^{-1})_{ji} X_j, \quad i = 1, \ldots, k
\]
(21)

Indeed, since $\det(\varphi) \neq 0$ the vector fields $Z_i$ also span the distribution $\mathcal{Z}$ and moreover satisfy the normalization condition $\langle d\varphi_i, Z_j \rangle = Z_j(\varphi_i) = \delta_{ij}$, as
\[
Z_j(\varphi_i) = \sum_{s=1}^k (\varphi^{-1})_{sj} X_s(\varphi_i) = \sum_{s=1}^k (\varphi^{-1})_{sj} \varphi_{is} = \delta_{ij}.
\]

Moreover, such choice of $Z_i$ makes the operator $\Pi$ $\mathcal{Z}$-invariant: if $L_{X_i} F = L_{X_i} G = 0$ for all $i$ then $L_{X_i} \{F,G\}_\Pi = \langle dF,(L_{X_i} \Pi) dG \rangle = 0$ since $L_{X_i} \Pi = 0$ ($\{X_i\}$ is just another basis of $\mathcal{Z}$). In this case the deformation (18) attains the form:
\[
\Pi_D = \Pi - \frac{1}{2} \sum_{i=1}^k X_i \wedge Z_i
\]
(22)
and is, as mentioned above, Poisson. It is easy to check this operator defines the following bracket on $C^\infty(\mathcal{M})$
\[
\{F,G\}_\Pi_D = \{F,G\}_\Pi - \sum_{i,j=1}^k \{F, \varphi_i\}_\Pi (\varphi^{-1})_{ij} \{\varphi_j, G\}_\Pi,
\]
(23)
(where $F,G : \mathcal{M} \to \mathbb{R}$ are two arbitrary functions on $\mathcal{M}$) which is just the well known Dirac deformation $\Pi$ of the bracket $\{\ldots\}_\Pi$ associated with $\Pi$. As we will show below in a more general context, $\ker(\Pi_D) = \text{Sp}\{d\varphi_i, dc_j\}_{i=1,\ldots,k, j=1,\ldots,r}$, i.e. the Dirac deformation preserves all the old Casimir functions $c_i$ and introduces new Casimirs $\varphi_i$.

In the case when all the vector fields $X_i$ are tangent to the foliation $\mathcal{S}$ (we call this case tangent case) the foliation $\mathcal{S}$ is Lagrangian with respect to any $\Omega$ dual to $\Pi$. Then the deformation (18) attains the form
\[
\Pi_D = \Pi - \sum_{i=1}^k X_i \wedge Z_i,
\]
(24)
and has been considered in [7] and in [8].

Let us observe that the formula (18) can be rewritten as
\[ \Pi = \Pi - \sum_i V_i \wedge Z_i \]
where the vector fields \( V_i \) were determined only up to a functional equation
\[ V_i = X_i + \sum_j \phi_{ji} Z_j. \]
Two natural solutions to this equation in the above mentioned two cases are
\[ V_i = \frac{1}{2} X_i \] (in Dirac case) or \( V_i = X_i \) (in tangent case) and they yield exactly the two above deformations (22) and (24) respectively.

In any case, our process of reducing the operator \( \Pi \) to \( \pi_R \) consists of two steps: we first deform \( \Pi \) to \( \Pi_D \) and then reduce in a natural way \( \Pi_D \) to \( \pi_R \) through a plain restriction:
\[ \pi_R = \Pi_D \mid_S. \]

Our construction generalizes the construction of Marsden and Ratiu in the following sense. Marsden and Ratiu presented in [2] a natural way of reducing a given Poisson bracket \( \{ \cdot, \cdot \}_\Pi \) on \( M \) to a Poisson bracket \( \{ \cdot, \cdot \}_{\pi_R} \) on a given submanifold \( S_0 \) (in our notation). Their method is non-constructive in the sense that in order to find the bracket \( \{ f, g \}_{\pi_R} \) of two functions \( f, g : S_0 \to R \) one has to calculate \( Z \mid_{S_0} \)-invariant prolongations of these functions. Our construction is performed on the level of bivectors rather than on the level of Poisson brackets. This construction (by deformation of the bivector \( \Pi \)) applies directly to every leaf of the distribution \( S \) and moreover it is constructive. At every leaf, however, both constructions are equivalent, as it is easy to see. Also, our construction can be extended to a similar construction for closed two-forms, as it is shown below. On the other hand, we make the assumption about the transversality of the distribution \( Z \) that was not present in the original paper of Marsden and Ratiu. This assumption is however very natural since it makes all the assumption of Poisson Reduction Theorem in [2] automatically satisfied.

Now we turn to an analogous question of reducing closed two-forms onto the foliation \( S \). Of course, there always exists a natural restriction of any closed two-form on any submanifold \( S_\nu \), obtained simply by restricting its domain to \( T S_\nu \). However, in the case that our closed two-form is a part of a dual P-p pair \( (\Pi, \Omega) \) it is also natural to consider a similar two-step procedure, where we first deform \( \Omega \) to \( \Omega_D \) (such that \( (\Pi_D, \Omega_D) \) is again a dual pair) and then restrict \( \Omega_D \) to a closed two-form \( \omega_R \) on \( S_\nu \) such that \( (\pi_R, \omega_R) \) is a dual P-p pair. This is the main aim of this paper.

Let us thus define, in analogy with (17), the following bilinear map:
\[ \Omega_D(U, V) = \Omega(U ||, V ||) \text{ for any vector fields } U, V \text{ on } M. \]
This map induces the following two-form \( \Omega_D \) on \( M \):
\[ \Omega_D = \Omega - \sum_{i=1}^k \xi_i \wedge d\phi_i - \frac{1}{2} \sum_{i,j=1}^k \xi_i(Z_j) d\phi_i \wedge d\phi_j \]
where the one-forms \( \xi_i \) are defined as
\[ \xi_i = \Omega(Z_i). \]

The two-form \( \Omega_D \) obviously restricts to the same two-form on \( S_\nu \) as \( \Omega \) does. That is, we can define a form \( \omega_R \) on every leaf of \( S \) through the plain restriction
of $\Omega_D$ (or $\Omega$) to $S_v$:

$$\omega_R \overset{\text{def}}{=} \Omega_D|_{S_v} \equiv \Omega|_{S_v}.$$  

It is obvious that $\Omega_D|_{S_v} \equiv \Omega|_{S_v}$ since the last two terms in (26) vanish on $S_v$.

Let us now assume that $(\Pi, \Omega)$ is a dual P-p pair in the sense of definitions (1) and (2). We will show that in the generic (Dirac) case and under certain conditions both pairs $(\Pi_D, \Omega_D)$ and $(\pi_R, \omega_R)$ are dual pairs.

**Theorem 17** Suppose that $(\Pi, \Omega)$ is a dual P-p pair with $\ker(\Pi) = Sp\{dc_i\}_{i=1, \ldots, r}$, $\ker(\Omega) = Sp\{Y_i\}_{i=1, \ldots, r}$ and with the corresponding foliation $\mathcal{N}$ of $\mathcal{M}$. Suppose also that the constraints $\varphi_j, j = 1, \ldots, k$ define a foliation $\mathcal{S}$ of $\mathcal{M}$ with some transversal distribution spanned by the vector fields $Z_i$ such that $\Pi$ is $\mathcal{Z}$-invariant and such that $Z_i(\varphi_j) = \delta_{ij}$. Suppose also that all $Y_i$ are tangent to $\mathcal{S}$ (i.e. $Y_i(\varphi_j) = 0$ for all $i, j$) and that all $Z_i$ are tangent to $\mathcal{N}$ (i.e. $Z_i(e_j) = 0$ for all $i, j$). Then the pair $(\Pi_D, \Omega_D)$ given by (26) and (27) has the following properties:

1. $\ker(\Pi_D) = Sp\{dc_i, d\varphi_j\}$, $\ker(\Omega_D) = Sp\{Y_i, Z_j\}$
2. In the generic (Dirac) case when $Z_i$ are obtained as in (24) the pair $(\Pi_D, \Omega_D)$ is a dual pair.

**Proof.** We have already showed that $\Pi_D d\varphi_i = 0$. A similar computation yields that $\Pi_D dc_i = 0$. Using (26) we obtain

$$\Omega_D(Y_j) = \Omega(Y_j) - \sum_{i=1}^k Y_j(\varphi_i)\xi_i + \sum_{i=1}^k \langle \xi_i, Y_j \rangle d\varphi_i - \frac{1}{2} \sum_{i,l=1}^k \xi_i(Z_l) (Y_j(\varphi_i)d\varphi_i - Y_j(\varphi_l)d\varphi_i)$$

$$= 0,$$

since $\Omega(Y_j) = 0$, $\langle \xi_i, Y_j \rangle = \Omega(Z_i, Y_j) = -\Omega(Y_j, Z_i) = 0$ and $Y_j(\varphi_i) = 0$ by assumption. Further

$$\Omega_D(Z_j) = \xi_j - \sum_{i=1}^r Z_j(\varphi_i)\xi_i + \sum_{i=1}^k \langle \xi_i, Z_j \rangle d\varphi_i - \frac{1}{2} \sum_{i,l=1}^k \xi_i(Z_l) (\delta_{ij}d\varphi_i - \delta_{ji}d\varphi_i) = 0$$

all due to $Z_j(\varphi_i) = \delta_{ij}$. This concludes the proof of the first statement. Using some elementary tensor relations one can (after some direct but cumbersome calculations) show that the pair $(\Pi_D, \Omega_D)$ satisfies the following identity on $T\mathcal{M}$:

$$I = \Pi_D \Omega_D + \sum_{i=1}^r Y_i \otimes dc_i + \sum_{j=1}^k Z_j \otimes d\varphi_j - T$$

(27)

where the $(1,1)$-tensor $T$ is of the form

$$T = \sum_{i=1}^k \left( X_i + \sum_{j=1}^k \varphi_{ij}Z_i \right) \otimes \left( \xi_i + \sum_{l=1}^k \xi_l(Z_i) d\varphi_l \right).$$
In the Dirac case the expressions in both parentheses in $T$ vanish for every $i$ due to (21) so that the whole tensor $T$ vanishes. Further, the relations $Y_i(\varphi_j) = 0$, $Y_i(c_j) = \delta_{ij}$, $Z_i(\varphi_j) = \delta_{ij}$, $Z_i(c_j) = 0$ are just part of our assumptions. Thus, in the Dirac case all the requirements of Definition 1 are satisfied.

We are now in position to prove the main theorem of this paper.

**Theorem 18** The pair $(\pi_R, \omega_R)$ obtained through the restriction $(\pi_R, \omega_R) = (\Pi_D, \Omega_D)|_{S_\nu}$ of $(\Pi_D, \Omega_D)$ given by (18) and (26) is in the Dirac case a dual P-p pair on every leaf $S_\nu$ of $S$ with the Casimirs $c_i|_{S_\nu}$, the kernel of $\omega_R$ spanned by $Y_i$ (notice that $Y_i$ are tangent to $S_\nu$) and with the partition of identity on $TS_\nu$ given by

$$I = \pi_R \omega_R + \sum_{i=1}^r Y_i \otimes d(c_i|_{S_\nu}).$$  \hspace{1cm} (28)

**Proof.** The proof of this theorem follows from the fact that $(\pi_R, \omega_R) = (\Pi_D, \Omega_D)|_{S_\nu}$. The partition of identity (28) follows from the partition (27) since $d\varphi_i|_{S_\nu} = 0$ and since $T = 0$ in the Dirac case. Further, $\pi_R$ is Poisson since $\Pi_D$ is. We only have to check that $\omega_R$ is closed.

Obviously, $\Omega_D$ is usually not closed, as according to (26) in the Dirac case we easily obtain

$$d\Omega_D = \frac{1}{2} \sum_{i=1}^k d\varphi_i \wedge d\xi_i \neq 0.$$  

However, $\omega_R = \Omega_D|_{S_\nu}$ so that $d\omega_R = d(\Omega_D|_{S_\nu}) = (d\Omega_D)|_{S_\nu} = 0$ due to the above formula, again since $d\varphi_i|_{S_\nu} = 0$. \hspace{1cm} \blacksquare

Thus, starting from a dual P-p pair $(\Pi, \Omega)$ and a proper foliation $S$ (defined by a Dirac second-class constraints $\varphi_i$) we have constructed a dual P-p pair $(\pi_R, \omega_R)$ on every leaf of $S$.

### 4 Examples

Let us now continue with Example 10 and Example 11. To illustrate our approach we will also construct the deformations $\Omega_D$ dual to the respective bivectors $\Pi_D$, although it is not necessary for the actual construction of the reductions $\omega_R$ that can be obtained directly by restricting $\Omega$ to $S_\nu$.

**Example 19** (Ex 10 continued). Assume that $n = 3$ and $r = 1$ so that the manifold $M$ is of dimension 7 and the local coordinates are $(q_1, q_2, q_3, p_1, p_2, p_3, c)$. The original dual P-p pair $(\Pi, \Omega)$ is given by (12). Let us now introduce a 5-dimensional submanifold $S_0$ through the following pair of constraints:

$$\varphi_1 \equiv q_1 q_2 + q_3 = 0, \quad \varphi_2 = p_1 + p_2 q_1 + p_3 q_2 = 0$$  \hspace{1cm} (29)

(for some motivation on the source of these constraints, see (12)) so that $k = 2$ here. The constraints (29) do not contain the Casimir function $c$ explicitly so
that the condition $Y(\varphi_i) = 0$ is satisfied as $Y = \frac{\partial}{\partial c}$. The $2 \times 2$ matrix $\varphi$ has the form:

$$\varphi = (2q_2 + q_1^2) \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$$

The vector fields $X_i$ and then $Z_i$ can be easily computed (21). The result is

$$X_1 = -q_2 \frac{\partial}{\partial p_1} - q_1 \frac{\partial}{\partial p_2} - \frac{\partial}{\partial p_3}, \quad X_2 = \frac{\partial}{\partial q_1} + q_1 \frac{\partial}{\partial q_2} + q_2 \frac{\partial}{\partial q_3} - p_2 \frac{\partial}{\partial p_1} - p_3 \frac{\partial}{\partial p_2}$$

$$Z_1 = \frac{1}{\varphi_{12}} X_2, \quad Z_2 = -\frac{1}{\varphi_{12}} X_1,$$

and one can see that $Z_i(c) = 0$ as $Z_i$ do not contain derivation with respect to the coordinate variable $c$. A direct computation of the expression (18) leads to

$$\Pi_D = \frac{1}{\varphi_{12}} \begin{bmatrix} A & 0_{6 \times 1} \\ -A^t & B \end{bmatrix}$$

with

$$A = \begin{bmatrix} q_2 + q_1^2 & -q_1 & -1 \\ -q_1 q_2 & 2q_2 & -q_1 \\ -q_2 & -q_1 q_2 & q_2 + q_1^2 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & p_2 q_1 - p_3 q_2 & p_2 \\ p_3 q_2 - p_2 q_1 & 0 & p_3 \\ -p_2 & -p_3 & 0 \end{bmatrix}.$$ 

It can be easily shown that $\Pi_D$ is indeed Poisson. The one-forms $\xi_i$ are given by

$$\xi_1 = \frac{1}{\varphi_{12}} d\varphi_2, \quad \xi_2 = \frac{1}{\varphi_{12}} d\varphi_1$$

and (22) yields

$$\Omega_D = \frac{1}{\varphi_{12}} \begin{bmatrix} -B & A^t \\ -A & 0 \end{bmatrix}$$

One can easily check that $d\Omega_D \neq 0$. However, $(\Pi_D, \Omega_D)$ is a dual pair with $Y = \frac{\partial}{\partial c}$. In order to obtain explicit expressions on $\pi_R$ and $\omega_R$ we pass to new coordinate system $(q_1, q_2, \varphi_1, \varphi_2, p_2, p_3, c)$ as the constraints (24) are in a natural way soluble with respect to $q_3, p_1$. In these Casimir variables our operators attain the form

$$\Pi'_D = \frac{1}{\varphi_{12}} \begin{bmatrix} 0_{3 \times 1} & \begin{bmatrix} \varphi_{12} A' \\ B' \end{bmatrix} \\ 0_{1 \times 6} & 0 \end{bmatrix}$$

with

$$A' = \begin{bmatrix} 0 & -q_1 & -1 \\ 0 & 2q_2 & -q_1 \\ 0 & 0 & 0 \end{bmatrix}, \quad B' = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & p_2 \\ 0 & -p_3 & 0 \end{bmatrix}.$$
\[ \Omega'_D = \begin{bmatrix} C' & D' \end{bmatrix} \begin{bmatrix} 0_{6 \times 1} \end{bmatrix}, \]

with
\[ C' = \begin{bmatrix} 0 & p_3 & 0 \\ -p_3 & 0 & 0 \\ 1 & q_1 & -p_3 \end{bmatrix}, \quad D' = \begin{bmatrix} -1 & q_1 & 2q_2 \\ 0 & -1 & q_1 \\ -1 & 0 & -1 \end{bmatrix}. \]

Now, if we parametrize the submanifold \( S_0 \) with the coordinates \( (q_1, q_2, p_2, p_3, c) \) then we can immediately obtain the expressions for \( \pi_R \) and \( \omega_R \):
\[
\pi_R = \frac{1}{\varphi_{12}} \begin{bmatrix} 0 & 0 & -q_1 & -1 & 0 \\ 0 & 0 & 2q_2 & -q_1 & 0 \\ 1 & -2q_2 & 0 & p_3 & 0 \\ 1 & q_1 & -p_3 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad \omega_R = \begin{bmatrix} 0 & p_3 & q_1 & 2q_2 & 0 \\ -p_3 & 0 & -1 & q_1 & 0 \\ -q_1 & -1 & 0 & 0 & 0 \\ -2q_2 & q_1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}.
\]

and it can be checked directly that it is indeed a dual P-p pair. For example, one can immediately check that
\[ I = \pi_R \omega_R + Y \otimes d(c|_{S_0}). \]

The presented example is very simple, but illustrative. Let us now turn to our non-canonical example.

**Example 20** (Ex 11 continued) This time we work with the dual P-p pair \([18],[19]\) written in coordinates \( (q_1, q_2, p_1, p_2, e) \). Observe that now \( e \) is not any Casimir variable (and hence a different letter to denote this odd variable). Let us now introduce a 3-dimensional submanifold \( S_0 \) through the following pair of constraints:
\[
\varphi_1 \equiv p_1 - 1 = 0, \quad \varphi_2 \equiv -p_2 p_1^2 + ep_1 p_1 + 2 \ln(q_1^2) = 0 \quad (30)
\]
so that \( k = 2 \) again. It is easy to check that \( Y(\varphi_1) = 0 \) and only a bit more difficult to see that \( Z_1(c) = 0 \) so that the assumptions of Theorem [14] are again satisfied. The calculations similar to those in Example [13] lead to
\[
\Pi_D = \begin{bmatrix} 0 & \frac{q_1^2}{2p_1} & 0 & q_1 & p_1 \\ -\frac{q_1^2}{2p_1} & 0 & 0 & A & p_2 + \frac{1}{p_1} \\ 0 & 0 & 0 & 0 & 0 \\ -q_1 & -A & 0 & 0 & e + \frac{4}{q_1 p_1} \\ -p_1 & -p_2 - \frac{4}{p_1} & 0 & -e - \frac{4}{q_1 p_1} & 0 \end{bmatrix},
\]
(\(p_1\) is now a Casimir for \(\Pi_D\)) with \(A = \frac{2p_1q_2}{q_1} + \frac{2e}{p_1} - \frac{eq_1^2}{q_1^2}\) and to

\[\Omega_D = \begin{bmatrix}
    0 & \frac{2p_1}{q_1} & B & -2\frac{1}{q_1} & \frac{1}{2}p_1p_2 - \frac{1}{2}eq_1 \\
    -2\frac{p_1}{q_1} & 0 & -2\frac{1}{q_1} & 0 & -\frac{1}{2}p_1^2 \\
    -B & 2\frac{1}{q_1} & 0 & 0 & C \\
    2\frac{1}{q_1} & 0 & 0 & 0 & \frac{1}{2}q_1p_1 \\
    \frac{1}{2}eq_1 - \frac{1}{2}p_1p_2 & \frac{1}{2}p_1^2 & -C & -\frac{1}{2}q_1p_1 & 0
\end{bmatrix},\]

with \(B = 4\frac{p_2}{q_1} - 2\frac{e}{p_1} - 8\frac{q_1}{p_1}, C = p_1q_2 - \frac{1}{2}q_1p_2 - 2\frac{2}{p_1}\). It turns out that in this case \(\Omega_D\) is closed so that here our pair \((\Pi_D, \Omega_D)\) is a dual P-p pair. In order to reduce this pair onto \(S\) we pass to the Casimir variables \((q_1, q_2, \varphi_1, \varphi_2, c)\) defined by constraints (30) together with (15) and (16)

\[
\begin{align*}
\varphi_1 &= p_1 - 1 \\
\varphi_2 &= -p_2p_1^2 + eq_1p_1 + 2\ln(q_1^2) \\
c &= -\frac{1}{2}q_2p_1^2 + \frac{1}{2}q_1p_1p_2 - \frac{1}{2}eq_1^2
\end{align*}
\]

It is possible to solve these equations with respect to \(p_1, p_2, e\). We get the expressions

\[
p_1 = p_1(q, \varphi, c) = \varphi_1 + 1, \quad p_2 = p_2(q, \varphi, c), \quad e = e(q, \varphi, c)
\]

that are however too complicated to present them explicitly. In these new variables the operator \(\Pi_D\) attains an almost canonical form

\[
\Pi_D' = \frac{q_1^2}{2(\varphi_1 + 1)} \begin{bmatrix}
    0 & 1 & 0_{2 \times 3} \\
    -1 & 0 & 0_{3 \times 2} \\
    0_{3 \times 2} & 0_{3 \times 3}
\end{bmatrix}
\]

while \(\Omega_D\) attains a rather complicated form.

\[
\Omega_D' = \begin{bmatrix}
    0 & -\frac{2p_1}{q_1} & \frac{2e}{p_1} - \frac{4q_2}{q_1} - \frac{2}{p_1^2} & \frac{2p_1q_2}{q_1^2} \\
    \frac{2p_1}{q_1} & 0 & -2\frac{1}{q_1} & 0 & -\frac{2}{p_1^2} \\
    \frac{2q_2}{q_1} - \frac{4p_1q_2}{q_1^2} & \frac{2}{p_1} & 0 & \frac{2}{q_1p_1} & A' \\
    \frac{2p_1p_2}{q_1} & 0 & -2\frac{1}{q_1} & 0 & -\frac{2}{q_1p_1} \\
    -\frac{2p_1p_2}{q_1} & \frac{2}{q_1} & -A' & \frac{2}{q_1p_1} & 0
\end{bmatrix},
\]

with \(A' = -\frac{2p_1}{q_1} + \frac{2e}{p_1} - \frac{4p_1q_2}{q_1^2}\) and with \(p_1, p_2, e\) given by (17). We are now ready to reduce our operators onto \(S_0\). The result is

\[
\pi_R = \frac{q_1}{2} \begin{bmatrix}
    0 & 1 & 0_{2 \times 1} \\
    -1 & 0 & 0_{1 \times 2} \\
    0_{1 \times 2} & 0 & 0
\end{bmatrix}, \quad \omega_R = \frac{2}{q_1} \begin{bmatrix}
    0 & -1 & B \\
    1 & 0 & -1 \\
    B & 1 & 0
\end{bmatrix}
\]

with \(B = (4c + 2q_2 - 2q_1\ln(q_1^2))/q_1\). Again it can be checked directly that it is indeed a dual P-p pair.
5 Conclusions

In this paper we have constructed a theory of Dirac-type reductions for Poisson bivectors and presymplectic (i.e. closed but in general degenerate) two-forms by embedding them in a geometrical object that we call 'dual pair'. We systematically constructed the theory of dual pairs and of their special type: Poisson-presymplectic pairs (i.e. dual pairs consisting of one Poisson operator and one closed two-form). Using this theory we presented how to project in principle any dual P-p pair onto submanifolds in such a way that the reduced pair is again a dual P-p pair. Our method is in a sense a generalization of the concepts of P.A.M. Dirac, J. Marsden and T. Ratiu. We concluded the article by two examples: one starting from a canonical dual pair and one non-canonical.
