TORELLI PROBLEM FOR CALABI-YAU THREEFOLDS WITH GLSM DESCRIPTION

MICHAŁ KAPUSTKA AND MARCO RAMPAZZO

ABSTRACT. We construct a gauged linear sigma model with two non-birational Kähler phases which we prove to be derived equivalent, L-equivalent, deformation equivalent and Hodge equivalent. This provides a new counterexample to the birational Torelli problem which admits a simple GLSM interpretation.

1. INTRODUCTION

There has been recently growing interest both from a point of view of algebraic geometry and string theory in the study of derived equivalent but non-isomorphic pairs of Calabi–Yau threefolds. The first and most famous example is the Pfaffian-Grassmannian equivalence observed in [Rød] and proved in [Kuz3, BC]. In this case the equivalence is also interpreted in [HTo, ADS] in terms of wall-crossing in the associated gauged linear sigma model (GLSM for short). This last construction has its roots in physics, in particular quantum field theory: from the seminal paper of Witten [Wit], a rich literature on the subject emerged, alimented by the profound connection with string theory dualities, in particular mirror symmetry. Different examples have been studied, mainly arising from toric varieties (i.e. giving an abelian GLSM.) while there are still few examples of GLSM associated to non-abelian gauge groups. Some explicit examples of non-abelian GLSM are studied in [JKLMR, DS] and these provide a new insight into mirror symmetry of determinantal Calabi–Yau threefolds. Moreover, a rigorous mathematical description of GLSM has been given in [FJR].

In [CDHPS], the authors study abelian GLSM theories with two non-birational Kähler phases and observe a relation with Kuznetsov’s homological projective duality [Kuz3]. They conjecture, in particular, that two Kähler phases of a GLSM are always twisted derived equivalent. Examples of such a phenomenon involving noncommutative varieties as well as partial proofs of the conjecture have been found in [CDHPS, Sha]. The case of non-abelian GLSM has been treated from the physics side in [Hor, HK, DS] leading to the same conjecture for symmetric and skew-symmetric degeneracy loci. The work of [Hor] has been reinterpreted in mathematical terms in [RS], where the conjecture was proven for both types of degeneracy loci. More generally, a relation between homological projective duality and variations of GIT stability for Landau-Ginzburg models has been established in [Renn1].

Note that up to now most known geometric constructions of non-abelian GLSM admitting two Kähler phases and leading to derived equivalent pairs of Calabi–Yau threefolds are obtained by determinantal constructions (see [Hor, HK, Renn2, HTa, JKLMR]). On the other hand, an interesting case of derived equivalent and non-birational pairs of Calabi–Yau threefolds was recently discovered in the context of the Torelli problem. This is the family $X_{25}$ of Calabi–Yau threefolds of degree 25 in $\mathbb{P}^9$ studied by [GP, Kap, Kan, OR, BCP]. The elements of this family, first introduced in [GP], are given by the intersection of two generic $\text{PGL}(10)$–translates of the Grassmannian $G(2, V_5)$ embedded in $\mathbb{P}^9$ via the Plücker embedding.

Independently, in [OR] and [BCP], it is proved that for a general Calabi–Yau threefold
\( \bar{X} \in \mathcal{X}_{25} \) intersecting the projective dual varieties of both translates one obtains another Calabi–Yau threefold \( \bar{Y} \in \mathcal{X}_{25} \) which is in general not isomorphic to \( \bar{X} \), but which is derived equivalent, deformation equivalent and Hodge equivalent to \( \bar{X} \). We shall say in such case that \( \bar{X} \) is dual to \( \bar{Y} \). Such general dual pairs of Calabi–Yau threefolds in \( \mathcal{X}_{25} \), in particular, provide counterexamples to the birational Torelli problem. Note that some GLSM interpretation of the duality on \( \mathcal{X}_{25} \) has just appeared in [CKS].

In [BCP], it is additionally shown that the following relation holds in the Grothendieck ring of varieties:

\[
([\bar{X}] - [\bar{Y}])L^4 = 0,
\]

where \( L \) is the class of the affine line. This means that \( \bar{X} \) and \( \bar{Y} \) are also so-called \( \mathbb{L} \)-equivalent.

A similar case has also been discussed in the work of Manivel [Man], where the intersection of two translates of the ten-dimensional spinor variety in the projectivization of a sixteen-dimensional half-spin representation has been investigated. Here the intersection is a Calabi–Yau fivefold, and the projective dual construction gives rise to a non-birational Calabi–Yau fivefold, still, the two varieties have been proven to be deformation equivalent, derived equivalent, \( \mathbb{L} \)-equivalent and Hodge equivalent. Moreover, in [BFMT], techniques to construct Calabi–Yau threefolds and fourfolds as orbital degeneracy loci have been explained. This leads, in particular, to all families discussed above and may serve as a source of further examples of derived equivalent and \( \mathbb{L} \)-equivalent pairs of Calabi–Yau manifolds.

Let us point out that the notion of \( \mathbb{L} \)-equivalence is somehow related to the notion of derived equivalence. The problem whether derived equivalence may imply \( \mathbb{L} \)-equivalence has been first considered in [IMOU2], and short after that the positive answer has been stated as a conjecture in [KS]. Note that it has already been proven (see [IMOU2, Efi]) that there is no implication between derived and \( \mathbb{L} \)-equivalence for abelian varieties. Still, up to now, no counterexample is known among simply connected Calabi–Yau manifolds.

In this paper, we consider the family \( \bar{\mathcal{X}}_{25} \) of Calabi–Yau threefolds given as zero loci of sections of the vector bundle \( Q^V(2) \) on \( G(2, V_5) \). As it was pointed out in [Kap, IIM] and [OR], these varieties, still being smooth, belong to the boundary of \( \mathcal{X}_{25} \) and can be interpreted as the intersections of infinitesimal translates of \( G(2, V_5) \). For each such a manifold \( X \) we provide a construction of a dual Calabi–Yau threefold \( \bar{Y} \) in the same family, which is not birational, but is derived equivalent and \( \mathbb{L} \)-equivalent to \( X \). Then, as pointed out in [OR, Prop 2.1], they are also Hodge equivalent i.e. their periods define equivalent integral Hodge structures. We furthermore observe that our duality concept is an extension of the duality studied in [OR, BCP] to the investigated boundary component \( \bar{\mathcal{X}}_{25} \) of \( \mathcal{X}_{25} \). As explained in [OR], we can then apply the Matsusaka–Mumford theorem (see [MM]), to provide another proof of the fact that a general element of \( \mathcal{X}_{25} \) and its dual are not isomorphic.

We notice furthermore that for \( X, Y \in \bar{\mathcal{X}}_{25} \) a dual pair of Calabi–Yau threefolds we have

\[
([X] - [Y])L^2 = 0.
\]

Comparing with (1), we see that the exponent of \( L \) in our formula which is valid on the boundary divisor \( \bar{\mathcal{X}}_{25} \) is smaller than the exponent known to annihilate the difference of classes of a dual pair in the general case \( \mathcal{X}_{25} \). A similar phenomenon occurs in the Pfaffian–Grassmannian equivalence. The exponent is known only to be bounded by 6 in general and it is proven to be 1 on a boundary divisor (see [IMOU1]). It is an interesting problem proposed in [KS] to understand the geometric meaning of the minimal exponent of \( L \) annihilating a difference of two classes of varieties. We hope that our example may provide further insight into that problem.
Finally, we present a GLSM description of Calabi–Yau manifolds in our family $\tilde{X}_{25}$ which explains the duality equivalence of $X$ and $Y$ in terms of wall crossing. We thus provide a GLSM construction with two non-birational Kähler phases with simple geometric realizations as zero loci of sections of a vector bundle, which are derived equivalent, deformation equivalent and $L$-equivalent.

Our argument relies on the following diagram that we establish in Section 2.

![Diagram](image)

The notation is the following:

- $V_5$ is a five-dimensional vector space and $G(k, V_5)$ stands for the Grassmannian of $k$ dimensional subspaces in $V_5$.
- $F$ is the flag variety given by the following incidence correspondence:

$$F = \{([V], [W]) \in G(2, V_5) \times G(3, V_5) : V \subset W}\) $$

- $\pi_1$ and $\pi_2$ are the natural projections from the flag variety $F$ to the two Grassmannians.
- The flag variety $F$ has Picard group generated by the pullbacks of the hyperplane sections of the two Grassmannians $G_1 = G(2, V_5)$ and $G_2 = G(3, V_5)$. We denote the pullbacks of the hyperplane sections of the Grassmannians $G(2, V_5)$ and $G(3, V_5)$ by $O(1, 0)$ and $O(0, 1)$ respectively. In this notation $M$ is a hyperplane section of the flag variety $F$, i.e. the zero locus of a section $s \in H^0(F, O(1, 1))$.
- We prove (see Lemma 2.1) that $(\pi_1)_*O(1, 1) = Q^1_2(2)$ and $(\pi_1)_*O(1, 1) = U_2(2)$, where we call $U_t$ the universal bundle of a Grassmannian $G_t$ and $Q_t$ its universal quotient bundle. The varieties $X$ and $Y$ are, respectively, the zero loci of the sections $(\pi_1)_*s$ and $(\pi_2)_*s$ of $Q^1_2(2)$ and $U_2(2)$.
- $f_1$ is a fibration over $G(2, V_5)$ with fiber isomorphic to $\mathbb{P}^1$, for points outside the subvariety $X$ whereas the fibers are isomorphic to $\mathbb{P}^2$ for points on $X$. Similarly $f_2$ is a map onto $G(3, V_5)$ whose fibers are $\mathbb{P}^1$ outside $Y$ and $\mathbb{P}^2$ over $Y$.

In Section 3, we prove that, in general, if $X$ and $Y$ are dual they are not birational. Using the fact that they have Picard number equal to 1, we just need to prove that they are not projectively equivalent. The latter is done in several steps. First, we prove that $X$ and $Y$ are contained in unique Grassmannians. Furthermore the hyperplane section $M$ of $F$ is also uniquely determined both by $X \subset G(2, V_5)$ and by $Y \subset G(3, V_5)$. We then deduce that a linear isomorphism between $X$ and $Y$ must lift to an involution of the flag variety $F$ that preserves $M$. We conclude by dimension count proving that the variety parametrizing hyperplane sections of $F$ which are fixed by any such involution on $F$ is of smaller dimension than the the space of all hyperplane sections of $F$.

The $L$-equivalence of $X$ and $Y$ is a direct consequence of diagram (3). It is presented in Section 4. In Section 5, we show that the derived categories of coherent sheaves of $X$ and $Y$ can be embedded in two different orthogonal decompositions of the derived category of the hyperplane section $M$ of the flag variety $F$. This fact allows us to prove the derived equivalence of $X$ and $Y$ with a sequence of mutations. Section 6 is devoted to the
establishing of a GLSM with two Kähler phases representing dual Calabi-Yau threefolds from the family $\bar{X}_{25}$.

2. THE DESCRIPTION OF THE DUALITY

Hereafter we will describe the families appearing in diagram (3) in greater detail. In particular, we define the notion of duality between elements of these families.

First of all, with Lemma 2.1 we establish a relation between the vector bundles we described in diagram (3) proving that the pushforwards of $\mathcal{O}(1,1)$ are exactly the bundles appearing in the diagram.

**Lemma 2.1.** Let $\mathcal{O}(1,1) = \pi_1^*\mathcal{O}_{G_1}(1) \otimes \pi_2^*\mathcal{O}_{G_2}(1)$ be the hyperplane bundle on the flag variety $F$. Then the pushforwards of $\mathcal{O}(1,1)$ with respect to $\pi_1$ and $\pi_2$ are, respectively, $Q^\vee(2)$ and $\mathcal{U}(2)$.

**Proof.** Observe that the flag variety $F$ can be interpreted as the projectivization of the rank 3 quotient bundle $Q^\vee$ on the Grassmannian $G(2,V_5)$, hence also the projectivization of $Q^\vee(2)$. In this case, we have the relative Euler sequence

$$0 \rightarrow \Omega^1_{G(2,V_5)/F}(a,b) \rightarrow Q^\vee(2) \rightarrow \mathcal{O}_{F_1}(1) \rightarrow 0$$

and on $G(3,V_5)$

$$0 \rightarrow \Omega^1_{G(3,V_5)/F}(a,b) \rightarrow \mathcal{U}(2) \rightarrow \mathcal{O}_{F_2}(1) \rightarrow 0$$

where for $i = 1,2$ we called $\mathcal{O}_{F_i}(1)$ the Grothendieck relative $\mathcal{O}_{P(\mathcal{E}_i)}(1)$ associated to the corresponding bundle $\mathcal{E}_1 = Q^\vee_1(2)$ and $\mathcal{E}_2 = \mathcal{U}_2(2)$. We can compute the first Chern class of the relative $\Omega^1_{G_i/F}$ from the relative tangent bundle sequences, which is

$$0 \rightarrow T_{G(3,V_5)/F} \rightarrow T_{F} \rightarrow T_{G(3,V_5)} \rightarrow 0$$

and the same sequence holds for $G(2,V_5)$. In both the sequences (5) and (6), computing the first Chern class we get $\mathcal{O}_{F_i}(1) = \mathcal{O}(1,1)$ for $i = 1,2$. The remaining part of the proof follows from a general fact that the pushforward of the Grothendieck line bundle of a vector bundle $\mathcal{E}$ with respect to the surjection to the base is $\mathcal{E}$. \qed

The picture emerging is the following:

$$\xymatrix{ & \mathcal{O}(1,1) \ar[ld]_{(\pi_1)_*} & \ar[rd]^{(\pi_2)_*} & \\
(8) & Q^\vee(2) & F & \mathcal{U}(2) & \\
X & \ar[u]\pi_1 & G(2,V_5) & \ar[u]^{\pi_2} & G(3,V_5) \ar[l]_{(\pi_1)_*} \ar[r]^{(\pi_2)_*} & Y}
$$

Moreover, we denote $X := Z(s_1)$ the variety of all the points in $G(2,V_5)$ where $s_1$ vanishes. But $p \in Z(s_1)$ is equivalent to $s(\pi_1^{-1}(p)) = 0$. Thus, since $F$ is a $\mathbb{P}^2$ bundle on $G(2,V_5)$, the fibers of the projection from $M$ to $G(2,V_5)$ over points outside $X = Z(s_1)$ are isomorphic to $\mathbb{P}^1$, whereas the fibers over $X$ will be isomorphic to $\mathbb{P}^2$. The same applies to $Y$ in $G(3,V_5)$ and the projection $\pi_2|_M$.

**Lemma 2.2.** Let $X$ be the zero locus of a section $s_1 \in H^0(G(2,V_5), Q^\vee(2))$. Then $s_1$ is uniquely determined by $X$ up to scalar multiplication.

Similarly, if $Y$ is the zero locus of a section $s_2$ of $\mathcal{U}(2)$ on $G(3,V_5)$, $s_2$ is uniquely determined by $Y$. 

Proof. We will prove the result for $G(2, V_5)$, the proof for the case of $G(3, V_5)$ is identical. Let us suppose $X$ is the zero locus of two sections $s_1$ and $\tilde{s}_1$. Then, the Koszul resolution with respect to these two sections reads

$$
\cdots \to Q(-2) \overset{\alpha_{s_1}}{\to} I_X \to 0
$$

and is isomorphic to $W$. We consider only the case of $M$ the stability of $Q$ analogous. Since $\tilde{s}_1$ there the pushforward $(\pi_1)_p$ is isomorphic to $\mathbb{P}$ for $p \in X$ and is isomorphic to $\mathbb{P}$ for $p \in G(2, V_5) \setminus X$. Similarly for $Y = Z(s_2) \subset G(3, V_5)$ there exists a unique hyperplane section $M$ of $F$ such that the fiber $(\pi_2)_p^{-1}((p)$ is isomorphic to $\mathbb{P}$ for $p \in Y$ and is isomorphic to $\mathbb{P}$ for $p \in G(3, V_5) \setminus Y$.

Proof. We consider only the case $X = Z(s_1) \subset G(2, 5)$ the other being completely analogous. Since $F$ is the projectivization of a vector bundle over $G(2, V_5)$, using Lemma 2.1, there the pushforward $(\pi_1)_s$ defines a natural isomorphism

$$H^0(F, O(1, 1)) = H^0(G(2, V_5), Q^\vee(2)).$$

Hence $s_1 = (\pi_1)_s(s)$ for a unique $s \in H^0(F, O(1, 1))$. We define $M = Z(s)$ which satisfies the assertion by the discussion above. The uniqueness of $M$ follows from Lemma 2.2. Indeed, for any hyperplane section $\tilde{M} = Z(\tilde{s})$, the fibers $(\pi_1|_{\tilde{M}})^{-1}(p)$ are isomorphic to $\mathbb{P}$ exactly for $p \in Z((\pi_1)_s, \tilde{s})$, but $Z((\pi_1)_s, \tilde{s}) = X$ only if $(\pi_1)_s$ is proportional to $s_2$ which means that $\tilde{s}$ is proportional to $s$ and proves uniqueness.

Note that, every isomorphism $f : G(2, V_5) \to G(3, V_5)$, is induced by a linear isomorphism $T_f : V_5 \to V_5^\vee$. It follows that $f_*Q^\vee(2) = U(2)$ and $f^*U(2) = Q^\vee(2)$.

Therefore, we can introduce the following notions of duality.

Definition 2.4. We define two Calabi-Yau threefolds $X = Z(s_1) \subset G(2, V_5)$ and $Y = Z(s_2) \subset G(3, V_5)$ for $s_1 \in H^0(G(2, V_5), Q^\vee(2))$, $s_2 \in H^0(G(3, V_5), U(2))$ to be duals if there exists $s \in H^0(F, O(1, 1))$ such that $s_1 = (\pi_1)_s$ and $s_2 = (\pi_2)_s$.

Definition 2.5. Given an isomorphism $f : G(2, V_5) \to G(3, V_5)$, we say $X \subset G(2, V_5)$ is $f$-dual to $Y \subset G(2, V_5)$ if $f(Y)$ is dual to $X$.

Lemma 2.6. $X$ is $f$-dual to $Y$ if and only if $Y$ is $f$-dual to $X$.

Proof. Let

$$f : G(2, V_5) \to G(3, V_5)$$

be an isomorphism and $T_f : V_5 \to V_5^\vee$ be the associated linear map. Let us define $P = G(2, V_5) \times G(3, V_5)$. Then the following map is clearly an involution:

$$\begin{array}{c}
P \\
\downarrow^f \\
(x, y) \quad \longmapsto \quad (f^{-1}(y), f(x))
\end{array}$$
Then $\iota_f$ induces another involution

$$H^0(P, \mathcal{O}_P(1, 1)) \xrightarrow{\iota_f} H^0(P, \mathcal{O}_P(1, 1))$$

(13)

Let us now fix a basis of $V_5$ inducing a dual basis on $V_5^\vee$, such that $T_f$ is the identity matrix with respect to these two bases. Then a section $s \in H^0(P, \mathcal{O}_P(1, 1))$ can be represented as a $10 \times 10$ matrix $S$ in the following way

$$s \longmapsto \psi_1(x)^T S \psi_2(y)$$

(14)

where $\psi_1$ and $\psi_2$ denote the Plücker embeddings of $G(2, V_5)$ and $G(3, V_5)$, respectively. Observe that in this case the action of $\tilde{\iota}_f$ on $S$ is the transposition. Now let us suppose the threefolds $X$ and $Y$ in $G(2, V_5)$ are $f$-duals. Then we have $\iota_f(X, f(Y)) = (Y, f(X))$ and this means that $Y$ is $f$-dual to $X$, namely the pair $(Y, f(X))$ is associated to the section $\tilde{\iota}(s)$ where $s \in H^0(P, \mathcal{O}_P(1, 1))$ is the hyperplane section defining $(X, f(Y))$.

\[ \square \]

**Remark 2.7.** In [OR, sec. 5], it is proven that $[v] \in \mathbb{P}(\mathfrak{gl}(V))$ defines a section $s_v$ of $\wedge^2 V(1)$, whose projection to $H^0(G(2, V_5), \wedge^2 \mathcal{Q}(2))$ cuts out the threefold $X_v$. Then $s_v$ corresponds to a $10 \times 10$ matrix $S$ that we defined in the proof of Lemma 2.6. Hence, from the proof of Lemma 2.6 follows that $X_v$ and $X_{[v^T]}$ are $f$-duals. This means that our $f$-duality is equivalent to the duality notion defined in [OR, sec. 5], extending the duality defined on $X_{25}$.

### 3. Non birationality of Dual Threefolds

In this section, we prove that a general section $s \in H^0(F, \mathcal{O}(1, 1))$ gives rise to two non-isomorphic Calabi–Yau threefolds $X = Z((\pi_1)_s)$ and $Y = Z((\pi_2)_s)$, this result will be stated in Theorem 3.6. Before proving the theorem, we will discuss some auxiliary results. In [BCP], an argument to show that every $X \subset X_{25}$ is contained in just one pair of Grassmannians has been explained. Using similar ideas, we will prove an analogous result for the boundary $X_{25}$ of the family, namely that every Calabi–Yau threefold in $X_{25}$ is contained in just one Grassmannian.

From now on we will make extensive use of Borel–Weil–Bott theorem, which allows to compute the cohomology of every Schur functor of the bundles $\mathcal{U}^\vee$ and $\mathcal{Q}^\vee$ on a Grassmannian. As we will see, most of the bundles we will deal with can be represented in such a way. For a detailed account on the topic we recommend [BCP], while for a more general approach on many different formulations of the Borel–Weil–Bott theorem we refer to [Wei].

**Lemma 3.1.** Let $X$ be a Calabi–Yau threefold described as the zero locus of a section of $\mathcal{Q}^\vee(2)$. Then the following equalities hold for every $t \geq 0$:

(15) $$H^0(G(2, V_5), \mathcal{Q}(-t)) = H^0(X, \mathcal{Q}|_X(-t));$$

(16) $$H^0(G(2, V_5), \wedge^2 \mathcal{Q}(-t)) = H^0(X, \wedge^2 \mathcal{Q}|_X(-t)).$$

In particular, $H^0(X, \mathcal{Q}|_X) \cong V$ and $H^0(X, \mathcal{Q}|_X(-t)) = H^0(X, \wedge^2 \mathcal{Q}|_X(-t)) = 0$ for $t$ strictly positive.

**Proof.** Let us consider the following short exact sequence which comes from tensoring the ideal sheaf sequence of $X$ with $\mathcal{Q}$:

(17) $$0 \longrightarrow \mathcal{I}_{X/G(2, V_5)} \otimes \mathcal{Q}(-t) \longrightarrow \mathcal{Q}(-t) \longrightarrow \mathcal{Q}|_X(-t) \longrightarrow 0$$
Given this sequence, we need to show the vanishing of the first two degrees of cohomology for $I_X/G(2,V_5) \otimes \mathcal{Q}$. To do this, we consider the sequence obtained tensoring with $\mathcal{Q}$ the Koszul resolution of the ideal sheaf of $X$:

\begin{align}
(18) \quad 0 & \longrightarrow \mathcal{Q}(-5-t) \xrightarrow{\emptyset} \mathcal{Q} \otimes \mathcal{Q}(-3-t) \longrightarrow \mathcal{Q} \otimes \mathcal{Q}(-2-t) \xrightarrow{\emptyset} I_X/G(2,V_5) \otimes \mathcal{Q}(-t) \longrightarrow 0
\end{align}

The bundles $\mathcal{Q}(-5-t)$ and $\mathcal{Q} \otimes \mathcal{Q}(-3-t)$ have no cohomology in degree 0 and 1: this follows from the isomorphisms

\begin{align}
(19) \quad \mathcal{Q}(-5-t) & \cong \wedge^2 \mathcal{Q} \otimes (\wedge^3 \mathcal{Q})^{(4+t)} \wedge^2 \mathcal{Q} \otimes \mathcal{Q}(-3-t) \cong (\wedge^3 \mathcal{Q})^{(2+t)} \otimes \wedge^2 \mathcal{Q} \otimes \mathcal{Q}
\end{align}

which, in turn, proves $H^0(G(2,V_5), \text{ker}(\emptyset)) = H^0(G(2,V_5), \text{coker}(\emptyset)) = 0$ in (18). Since $\mathcal{Q} \otimes \mathcal{Q}(-2-t)$ has no cohomology in the first two degrees, due to $\mathcal{Q} \otimes \mathcal{Q}(-2-t) \cong (\wedge^3 \mathcal{Q})^{(2+t)}$, then also $H^0(G(2,V_5), I_X/G(2,V_5) \otimes \mathcal{Q}) = 0$ and $H^1(G(2,V_5), I_X/G(2,V_5) \otimes \mathcal{Q}) = 0$. This, together with (17), proves our claim (15). The second equality follows from a totally analogous computation, namely it involves the tensor product of the ideal sheaf sequence with the wedge square of $\mathcal{Q}$.

\begin{lemma}
Let $X$ be a Calabi–Yau threefold described as the zero locus of a section of $\mathcal{Q}^t(V)$. Then the restriction $\mathcal{Q}^t(V)|_X$ is slope-stable.
\end{lemma}

\begin{proof}
The Mumford slope of a vector bundle is invariant up to twists and dualization, so the problem reduces to asking whether $\mathcal{Q}|_X$ is stable. Therefore, let us suppose there exists a subobject $\mathcal{F} \subset \mathcal{Q}|_X$. Then, since $G(2,V_5)$ has Picard number one, we have $c_1(\mathcal{F}) = O(t)$ and this leads to the injection

\begin{align}
(20) \quad 0 & \longrightarrow O \longrightarrow \wedge^r \mathcal{Q}|_X(-t)
\end{align}

where $r$ is the rank of $\mathcal{F}$, which can be one or two. To have $\mathcal{F}$ as a destabilizing object for $\mathcal{Q}|_X$, $t$ must be strictly positive in order to satisfy the inequality of Mumford slopes

\begin{align}
\frac{t}{r} = \mu(\mathcal{F}) \geq \mu(\mathcal{Q}|_X) = \frac{1}{3}.
\end{align}

On the other hand, the injection in (20) means that $\wedge^r \mathcal{Q}|_X(-t)$ has global sections: what is left to prove is that it can be true only for zero or negative $t$. The latter follows from Lemma 3.1.

\end{proof}

Let us suppose $X$ is contained in two Grassmannians $G_1$ and $G_2$, where the latter is the image of the former under an isomorphism of $\mathbb{P}^9$. Since both the restrictions of the normal bundles $\mathcal{N}_{i}|_X = \mathcal{N}_{G_i/\mathbb{P}^9}|_X = \mathcal{Q}_i^t(2)|_X$ are stable, every morphism between them must be zero or an isomorphism. Below we furthermore prove that the isomorphism class of the normal bundle determines the Grassmannian. Combining these two facts will give us the uniqueness of the Grassmannian containing $X$.

\begin{lemma}
Let $X$ be a Calabi–Yau threefold described as the zero locus of a section of $\mathcal{Q}^t(V)$. Then the following isomorphism holds:

\begin{align}
(22) \quad H^0(\mathbb{P}^9, O(1)) \cong H^0(X, O_X(1))
\end{align}

\begin{proof}
The claim follows by proving separately that $H^0(\mathbb{P}^9, O_{\mathbb{P}^9}(1)) \cong H^0(G(2,V_5), O_{G(2,V_5)}(1))$ and $H^0(G(2,V_5), O_{G(2,V_5)}(1)) \cong H^0(X, O_X(1))$. The first isomorphism comes from the $O(1)$-twist of the Koszul resolution of the ideal sheaf of $G(2,V_5) \subset \mathbb{P}^9$, which proves the vanishing of the cohomology of $I_{G(2,V_5)}(1)$, thus the desired result. The second isomorphism is proved in a similar way, with the resolution

\begin{align}
(23) \quad 0 \longrightarrow O(-4) \longrightarrow V_5 \otimes O(-2) \longrightarrow V_5 \otimes O(-1) \longrightarrow I_{G(2,V_5)}/\mathbb{P}^9(1) \longrightarrow 0
\end{align}

and Kodaira’s vanishing theorem.
\end{proof}

\begin{lemma}
Let $X \in \mathcal{R}_{25}$. Then the isomorphism class of $\mathcal{N}_{G(2,V_5)/\mathbb{P}^9}|_X$ determines the isomorphism $\psi : \wedge^2 V_5 \rightarrow W$, where $V_5$ is a five dimensional vector space and $W \cong H^0(\mathbb{P}^9, O(1))$.
\end{lemma}
Proof. Since $\mathcal{N}_{G(2,V_5)/P^0} \cong Q^\vee(2)$, the restriction of the normal bundle is determined by the restriction of the quotient bundle. Let us begin noting that the surjection
\begin{equation}
V_5 \otimes \mathcal{O} \rightarrow Q \rightarrow 0
\end{equation}
implies the following
\begin{equation}
\wedge^3 V_5 \otimes \mathcal{O} \rightarrow \wedge^3 Q \rightarrow 0.
\end{equation}
Let us observe that $\wedge^3 Q \cong \mathcal{O}(1)$. Then, this last surjection tells us that
\begin{equation}
H^0(G(2,V_5), \mathcal{O}(1)) \cong \wedge^3 H^0(G(2,V_5), Q).
\end{equation}
From Lemma 3.1 we have that $H^0(G(2,V_5), Q) \cong H^0(X, Q|_X)$, while Lemma 3.3 tells us that $H^0(P^0, O(1)) \cong H^0(X, O(1))$. Then, since $H^0(G(2,V_5), Q) \cong V_5$, we get an isomorphism $\wedge^3 V_5 \rightarrow W^\vee$ whose dual is exactly $\psi$ since $\wedge^3 V_5 \cong \wedge^2 V_5^\vee$.

Corollary 3.5. If $X \subset P^9$ is a Calabi–Yau threefold from the family $\tilde{X}_{25}$, then $X$ is contained in a unique Grassmannian $G(2,5)$ in its Plücker embedding.

Proof. Suppose that $X$ is contained in two Grassmannians $G_1, G_2$ for each of them we have an exact sequence:
\begin{equation}
0 \rightarrow \mathcal{N}_{X[G_1]} \rightarrow \mathcal{N}_{X[P^9]} \rightarrow \mathcal{N}_{G_1[P^9]|_X} \rightarrow 0
\end{equation}
Combining the two exact sequences we obtain a map: $\phi : \mathcal{N}_{X[G_1]} \rightarrow \mathcal{N}_{G_1[P^9]|_X}$. Note that we have $\mathcal{N}_{X[G_1]} \cong \mathcal{N}_{G_1[P^9]|_X} \cong Q'_i(2)|_X$. By stability of $Q'_i(2)$ we have $\phi$ is either trivial or an isomorphism. If it is an isomorphism it induces an isomorphism $\mathcal{N}_{G_1[P^9]|_X} \cong \mathcal{N}_{G_2[P^9]|_X}$ and we conclude by Lemma 3.4. If it is trivial it lifts to an isomorphism $\mathcal{N}_{X[G_1]} \cong \mathcal{N}_{X[G_2]}$ which again gives an isomorphism $\mathcal{N}_{G_1[P^9]|_X} \cong \mathcal{N}_{G_2[P^9]|_X}$ and permits us to conclude again by Lemma 3.4.

Now we are ready to prove the main theorem of this section.

Theorem 3.6. Let $F$ be the partial flag manifold $F(2,3,V_5)$, let $\pi_1$ and $\pi_2$ be the projections to the two Grassmannians $G(2,V_5)$ and $G(3,V_5)$.
Then a general section $s \in H^0(F,O(1,1))$ gives rise to two non-birational Calabi–Yau threefolds $X = Z((\pi_1)_*s)$ and $Y = Z((\pi_2)_*s)$.

Proof. Because of Lemma 2.2, we deduce that if there exists an isomorphism mapping $X$ to $Y$, then it is given by a map $f : G(2,V_5) \rightarrow G(3,V_5)$. Recall that such a map is determined by a linear isomorphism from $T_f : V_5 \rightarrow V_5^\vee$.

Thus, because of Corollary 3.5, $X$ and $Y$ are dual and isomorphic only if there exist $f : G(2,V_5) \rightarrow G(3,V_5)$ such that $X$ is $f$-dual to itself. This translates to the fact that the section defining $X$ on $F$ is in the fixed locus of the action of $\tilde{\iota}_f$ onto $H^0(F,O(1,1))$ induced by the action of $\tilde{\iota}_f$ onto $H^0(P,O(1,1))$ described in Lemma 2.6, namely $X$ is $f$-dual to $X$ if and only if $s$ is fixed by $\tilde{\iota}_f$. Note that $H^0(F,O(1,1))$ is a quotient of $H^0(F,O(1,1))$.

The fixed locus of $\tilde{\iota}_f$ onto $H^0(F,O(1,1))$ has two components: $L^+$, of dimension 55, which corresponds to symmetric matrices in the chosen bases, and $L^-$, of dimension 45, which is given in terms of skew-symmetric matrices. The 75-dimensional space $K = H^0(F,O(1,1))$ is the quotient of $H^0(F,O(1,1))$ by the subspace $I = H^0(P, \mathcal{I}_{F/P}(1,1))$ being 25-dimensional. In order to compute the dimensions of the fixed loci of the action of $\tilde{\iota}_f$ on $K$ we need to compute the dimensions of the fixed loci of the action of $\tilde{\iota}_f$ on $I$. Indeed,
\[ \dim K^+ = \dim L^+ - \dim (L^+ \cap I) \]
and
\[ \dim K^- = \dim L^- - \dim (L^- \cap I) \]
Let us fix a volume form on \( V_5 \) which gives an identification \( \Lambda^3 V_5 = \Lambda^2 V_5' \). Then for every \( x^* \otimes y \in V_5' \otimes V_5 \) we define \( s_{x^* \otimes y} \in H^0(P, O(1,1)) \) via
\[
s_{x^* \otimes y}(\alpha, \omega) = \omega(x^*) \wedge \alpha \wedge y,
\]
for \( \omega \in \Lambda^2 V_5' = \Lambda^3 V_5, \alpha \in \Lambda^2 V_5 \). Note that:
\[
s_{x^* \otimes y}(\alpha, \omega) = 0 \quad \text{for } \{ [\alpha], [\omega] \} \in F(2, 3, V_5) \subset \mathbb{P}(\Lambda^2 V_5) \times \mathbb{P}(\Lambda^3 V_5).
\]
Furthermore, the sections \( s_{x^* \otimes y} \) span together a 25-dimensional subspace of \( H^0(P, O(1,1)) \).

In consequence, by dimension count the above sections generate the space \( I \).

Let us fix a basis \( e_1, \ldots, e_5 \) of \( V_5 \) such that it defines a basis \( e_1', \ldots, e_5' \) on \( V_5' \) so that the map \( T_f : V_5 \to V_5' \) is represented by the identity matrix in these bases. We have a 25-dimensional subspace \( I \subset H^0(P, O(1,1)) \) spanned by linearly independent sections corresponding to \( x^* = e_i^*, y = e_j \) for \( i, j \in \{1, \ldots, 5\} \). These sections correspond to \( 10 \times 10 \) matrices representing elements of \( \Lambda^2 V_5 \otimes \Lambda^2 V_5' = \text{Hom}(\Lambda^2 V_5, \Lambda^2 V_5) \) in the basis \( \{ e_k \wedge e_l : k \neq l \} \) of \( \Lambda^2 V_5 \). Note that our choice of basis implies that \( \bar{\tau}_f \) acts on these matrices by transposition. On the other hand, we see that the matrix given by \( (e^*_i, e_j) \) is the transpose of the matrix corresponding to \( (e^*_j, e_i) \). Hence, the fixed locus of the action of transposition on \( I \) has two components of dimension 10 and 15. This means that \( \dim(I \cap L^+) = 15 \) and \( \dim(I \cap L^-) = 10 \).

We infer that \( \dim(K^+) = 55 - 15 = 40 \) and \( \dim(K^-) = 45 - 10 = 35 \).

By dimension count, the variety of all sections being fixed by some of the studied automorphisms \( \bar{\tau}_f \) is of dimension at most \( \max\{ \dim K^+, \dim K^- \} + \dim \text{Hom}(V_5, V_5') = 40 + 25 = 65 \), whereas the space of all sections is 75-dimensional. Thus a generic section is not isomorphic to any automorphisms of the flag variety \( F \) induced by an isomorphism \( V_5 \to V_5' \). This implies that the generic hyperplane section \( s \) of the flag variety yields two Calabi–Yau threefolds \( X \) and \( Y \) which are not projectively isomorphic. By the fact that the studied manifolds have Picard number one we conclude that they are not birational.

**Corollary 3.7.** If \( \bar{X}, \bar{Y} \) are general Calabi–Yau threefolds in \( \mathcal{X}_{25} \) which are dual in the sense of [OR, BCP] then they are not birational.

**Proof.** Consider an open neighborhood \( \mathfrak{U} \subset \mathcal{X}_{25} \) of a general \( X \in \mathcal{X}_{25} \). Consider also the family \( \mathfrak{V} \) of duals parametrized by \( \mathfrak{U} \). Now \( \mathfrak{U} \) and \( \mathfrak{V} \) are families of polarized Calabi–Yau threefolds such that, by Theorem 3.6, there exists a fiber of \( \mathfrak{U} \) which is not isomorphic to the corresponding fiber of \( \mathfrak{V} \). Then by the Matsusaka–Mumford theorem [MM] the corresponding general fibers are not isomorphic and consequently general dual pairs in \( \mathcal{X}_{25} \) are not isomorphic.

### 4. The \( L \)-equivalence in the Grothendieck ring of varieties

Hereafter we will show how, in the relation (1), the power of \( L \) drops to two. This result is due to the characteristics of the fibrations described in (3), which are special to \( \mathcal{X}_{25} \).

**Theorem 4.1.** Let \( s \) be a generic section of \( O(1,1) \) on the flag \( F \), let \( \pi_1 \) and \( \pi_2 \) be the projections to \( G(2, V_5) \) and \( G(3, V_5) \). Then, given \( X = Z((\pi_1)_s) \) and \( Y = Z((\pi_2)_s) \), we have the following relation in the Grothendieck ring of varieties, where \( \mathbb{L} \) is the class of the affine line.

\[
([X] - [Y]) \mathbb{L}^2 = 0
\]

**Proof.** With the aid of previous results, the proof is immediate: since the maps \( \pi_i \) define \( \mathbb{P}^2 \)-fibrations on the Calabi–Yau threefolds and \( \mathbb{P}^1 \)-fibrations elsewhere, we can write the following relations in the Grothendieck ring of varieties:

\[
[M] = [X][\mathbb{P}^2] + [G(2, V_5) \setminus X][\mathbb{P}^1]
\]
\[ [M] = [Y][\mathbb{P}^2] + [G(3, V_5) \setminus Y][\mathbb{P}^1] \]

Since \( X \) and \( Y \) are not isomorphic, we can compare the two expressions and, using properties of the Grothendieck ring of varieties, we get

\[ 0 = [X](\mathbb{P}^2) - [X](\mathbb{P}^1) - [Y](\mathbb{P}^2) - [Y](\mathbb{P}^1) \]

which, via the well-known formula

\[ [\mathbb{P}^n] = 1 + L + L^2 + \cdots + L^n, \]

yields the desired result. \( \square \)

5. Derived equivalence

From a theorem of Orlov in [Orl1], we deduce the following orthogonal decompositions for a hyperplane section of \( F \):

\[
D^b(M) = \left\langle D^b(G(2, V_5)), D^b(G(2, V_5)) \otimes O(1, 1), \pi_1^* D^b(X) \right\rangle \\
= \left\langle D^b(G(3, V_5)), D^b(G(3, V_5)) \otimes O(1, 1), \pi_2^* D^b(Y) \right\rangle
\]

In the remainder of this section, we will provide a sequence of mutation with the aim of proving the following equivalence of categories:

\[
\left\langle D^b(G(3, V_5)), D^b(G(3, V_5)) \otimes O(1, 1), \pi_2^* D^b(Y) \right\rangle \xrightarrow{\sim} \left\langle D^b(G(2, V_5)), D^b(G(2, V_5)) \otimes O(1, 1), \Phi D^b(Y) \right\rangle
\]

where \( \Phi \) is a functor given by a composition of mutations. That would prove an equivalence between this last exceptional collection and (32), thus proving that \( D^b(X) \cong D^b(Y) \).

Exceptional collections for Grassmannians and flag varieties have been described by Kapranov in [Kapr], where a method to construct them has been given in terms of Schur functors of the universal bundle, but we will use the minimal Lefschetz decomposition for \( G(2, V_5) \) introduced by Kuznetsov in [Kuz2]. The advantage of this collection, which can be recovered from the Kapranov one with a sequence of mutations as explained in [Kuz2], is that it generates a very simple helix involving only twists of two vector bundles. The collection is the following:

\[
D^bG(2, V_5) = \langle O, U^\vee, O(1), U^\vee(1), O(2), U^\vee(2), O(3), U^\vee(3), O(4), U^\vee(4) \rangle
\]

The duality isomorphism between \( G(2, V_5) \) and \( G(3, V_5) \) exchanges \( U^\vee \) with \( Q \) and allows us to write a minimal Lefschetz exceptional collection for \( G(3, V_5) \):

\[
D^bG(3, V_5) = \langle O, Q, O(1), Q(1), O(2), Q(2), O(3), Q(3), O(4), Q(4) \rangle.
\]

Now, before venturing in the computation of the mutations which will lead to the derived equivalence, let us prove some useful cohomology calculations: to avoid potential confusion, the tilde will denote pullback bundles from \( G(3, V_5) \), while the bundles without tilde will be pullbacks from \( G(2, V_5) \).

**Lemma 5.1.** The following relation holds for non negative integers \( a, b \) which satisfy \( 2 + a \leq b \leq 7 + a \) except for \( b = 3 + a \):

\[
\text{Ext}^*(\tilde{Q}(1, b), O(2, 2 + a)) = 0
\]

**Proof.** The proof is merely an application of Borel–Weil–Bott theorem, in particular, we are interested in understanding on which conditions on \( a \) and \( b \) we can obtain \( H^0(F, \tilde{Q}^\vee(1, 2 + a - b)) = 0 \).

Due to the Leray spectral sequence, our problem simplifies to showing that the push-forward of this bundle with respect to one of the two projections from the flag has no
Namely, due to the projection formula, we have:

\[(\pi_2)_* \tilde{Q}^\vee(1, 2 + a - b) = \tilde{U}(1) \otimes \tilde{Q}^\vee(2 + a - b) = \wedge^2 \tilde{U} \otimes \tilde{Q}^\vee(2 + a - b) = \wedge^2 \tilde{U} \otimes \left(\lambda^3 \tilde{U}\right)^{(2 + a)} \otimes \tilde{Q}^\vee \otimes \left(\lambda^2 \tilde{Q}^\vee\right)^{(b)}\]

The Bott–Weil theorem states that cohomology vanishes in every degree if two or more of the following integers coincide:

\[9 + a; 8 + a; 5 + a; 3 + b; 1 + b.\]

and this completes the proof. \(\square\)

A similar result can be obtained with the same argument:

**Lemma 5.2.** The following relation holds for non-negative integers \(a, b\) which satisfy \(3 + a \leq b \leq 7 + a:\)

\[\text{Ext}^\bullet(\mathcal{O}(1, b), \mathcal{O}(2, 2 + a)) = 0\]

Another useful vanishing condition comes from the Leray spectral sequence:

**Lemma 5.3.** Let \(\mathcal{F}\) and \(\mathcal{F}'\) be vector bundles on \(F\) such that they are pullbacks of vector bundles on the same Grassmannian. Then the following relation holds for every \(a, b, c, d\) such that \(d - b\) is either one or two:

\[\text{Ext}^\bullet(\mathcal{F}(a, b), \mathcal{F}'(c, d)) = 0\]

**Proof.** We observe that \(\mathcal{F}^\vee(-a, -b) \otimes \mathcal{F}'(c, d) = \pi_1^\vee(\mathcal{F}^\vee \otimes \mathcal{F}'(c - a)) \otimes \pi_2^\vee(d - b).\)

The pushforwards of \(\pi_2^\vee\mathcal{O}(-1)\) and \(\pi_2^\vee\mathcal{O}(-2)\) to \(G(2, \mathcal{V}_5)\) have no cohomology, thus \(\mathcal{F}^\vee(-a, -b) \otimes \mathcal{F}'(c, d)\) is acyclic. Due to the Leray spectral sequence we have

\[H^0(F, \mathcal{F}^\vee(-a, -b) \otimes \mathcal{F}'(c, d)) = H^0(G(2, \mathcal{V}_5), (\pi_1)_*\mathcal{F}^\vee(-a, -b) \otimes \mathcal{F}'(c, d))\]

and this yields the desired result. \(\square\)

The following lemmas provide some useful mutations which we will use in the further computations.

**Lemma 5.4.** We have the following mutation in the derived category of a Grassmannian \(G(k, \mathcal{V}_5)\) for every choice of the integers \(a, b:\)

\[L_{\mathcal{O}(a, b)}\mathcal{U}(a, b) = \mathcal{Q}(a, b)\]

**Proof.** The following fact

\[\text{Ext}^\bullet(\mathcal{Q}(a, b), \mathcal{O}(a, b)) = \mathbb{C}^n[0]\]

follows from Borel–Weil–Bott theorem, it tells us that the mutation we are interested in is the cone of the morphism

\[\mathcal{V}_5 \otimes \mathcal{O} \to \mathcal{Q}.\]

From the universal sequence

\[0 \to \mathcal{U} \to \mathcal{V}_5 \otimes \mathcal{O} \to \mathcal{Q} \to 0\]

we see that the morphism is surjective, thus the cone yields the kernel \(\mathcal{U}\). \(\square\)

**Lemma 5.5.** In the derived category of \(G(3, \mathcal{V}_5)\) the following mutations can be performed:

\[\text{Ext}^\bullet(\mathcal{Q}(a, b), \mathcal{O}(a, b)) = \mathbb{C}^n[0]\]

\[R_{\mathcal{O}(a+1, b-1)}\tilde{Q}(a, b) = \mathcal{Q}(a, b)\]

\[R_{\mathcal{O}(a+1, b-1)}\tilde{U}(a, b) = \mathcal{U}(a, b)\]
Proof. With Borel–Weil–Bott theorem we can compute the following:

\begin{equation}
\mathrm{Ext}^*(\tilde{Q}(a, b), \mathcal{O}(a + 1, b - 1)) = \mathbb{C}[-1]
\end{equation}

so a mutation involving that $\mathrm{Ext}$ is an extension. The relevant exact sequence is

\begin{equation}
0 \rightarrow \mathcal{O}(1, -1) \rightarrow Q \rightarrow \tilde{Q} \rightarrow 0,
\end{equation}

which can be found computing the rank one cokernel of the injection $U \hookrightarrow \tilde{U}$, comparing the universal sequences of the two Grassmannians and applying the Snake Lemma, this proves our first claim.

In order to verify the second one, we write the sequence involving the injection between the universal bundles, which is

\begin{equation}
0 \rightarrow U \rightarrow \tilde{U} \rightarrow \mathcal{O}(1, -1) \rightarrow 0.
\end{equation}

The related $\mathrm{Ext}$, in this case, is $\mathbb{C}[0]$, so the mutation is the cone of the relevant morphism, yielding the desired result.

Now we are ready to introduce the following result, which is the key of the proof of the derived equivalence.

**Proposition 5.6.** Let $X$ and $Y$ the zero loci of the pushforwards of $s \in H^0(F, \mathcal{O}(1, 1))$. Then the following functor is an equivalence of categories

\begin{equation}
\langle D^b(G(3, V_5)), D^b(G(3, V_5)) \otimes \mathcal{O}(1, 1), \pi_2^* D^b(Y) \rangle \overset{\sim}{\rightarrow} \langle D^b(G(2, V_5)), D^b(G(2, V_5)) \otimes \mathcal{O}(1, 1), \Phi \circ \pi_2^* D^b(Y) \rangle
\end{equation}

where $\Phi$ is a functor given by a composition of mutations.

**Proof.** The idea of the proof is writing the collection for the hyperplane section in a way such that we can use our cohomology vanishing results to transport line bundles $\mathcal{O}(a + 1, b - 1)$ to the immediate right of $\tilde{Q}(a, b)$, then use Lemma 5.5 to get rid of $\tilde{Q}(a, b)$, thus transforming vector bundles on $G(2, V_5)$ to vector bundles on $G(3, V_5)$. The exceptional collection for $M$ with the $G(3, V_5)$ description is the following:

\[
D^b(M) = \langle \mathcal{O}, \tilde{Q}, \mathcal{O}(0, 1), \tilde{Q}(0, 1), \mathcal{O}(0, 2), \tilde{Q}(0, 2), \mathcal{O}(0, 3), \tilde{Q}(0, 3), \mathcal{O}(0, 4), \tilde{Q}(0, 4), \\
\mathcal{O}(1, 1), \tilde{Q}(1, 1), \mathcal{O}(1, 2), \tilde{Q}(1, 2), \mathcal{O}(1, 3), \tilde{Q}(1, 3), \mathcal{O}(1, 4), \tilde{Q}(1, 4), \mathcal{O}(1, 5), \tilde{Q}(1, 5), \pi_2^* D^b(Y) \rangle
\]

Our first operation is sending the first five bundles to the end, they get twisted with the anticanonical bundle of $M$, which, with the adjunction formula, can be shown to be $\omega_M = \mathcal{O}(2, 2)$.

\[
D^b(M) = \langle \tilde{Q}(0, 2), \mathcal{O}(0, 3), \tilde{Q}(0, 3), \mathcal{O}(0, 4), \tilde{Q}(0, 4), \mathcal{O}(1, 1), \tilde{Q}(1, 1), \mathcal{O}(1, 2), \tilde{Q}(1, 2), \mathcal{O}(1, 3), \\
\tilde{Q}(1, 3), \mathcal{O}(1, 4), \tilde{Q}(1, 4), \mathcal{O}(1, 5), \tilde{Q}(1, 5), \mathcal{O}(2, 2), \tilde{Q}(2, 2), \mathcal{O}(2, 3), \tilde{Q}(2, 3), \mathcal{O}(2, 4), \phi_1 D^b(Y) \rangle
\]

where we introduced the functor

\begin{equation}
\phi_1 = R_{\mathcal{O}(2, 2), \tilde{Q}(2, 2), \mathcal{O}(2, 3), \tilde{Q}(2, 3), \mathcal{O}(2, 4)} \circ \pi_2^*
\end{equation}

Applying Lemma 5.1, we observe that $\mathcal{O}(1, 1)$ can be moved next to $\tilde{Q}(0, 2)$. Then we can use Lemma 5.5 sending $\tilde{Q}(0, 2)$ to $Q(0, 2)$. This can be done twice due to the invariance
of the operation up to overall twists, yielding:

\[ D^b(M) = \langle \mathcal{O}(1,1), \mathcal{Q}(0,2), \mathcal{O}(0,3), \hat{\mathcal{Q}}(0,3), \mathcal{O}(0,4), \hat{\mathcal{Q}}(0,4), \hat{\mathcal{Q}}(1,1), \mathcal{O}(1,2), \hat{\mathcal{Q}}(1,2), \mathcal{O}(1,3), \mathcal{O}(2,2), \mathcal{Q}(1,3), \mathcal{O}(1,4), \mathcal{O}(2,3), \hat{\mathcal{Q}}(1,4), \mathcal{O}(1,5), \hat{\mathcal{Q}}(1,5), \hat{\mathcal{Q}}(2,2), \hat{\mathcal{Q}}(2,3), \mathcal{O}(2,4), \phi_1 D^bY \rangle \]

We are tempted to perform the same operation with \( \hat{\mathcal{Q}}(0,3) \) and \( \mathcal{O}(1,2) \), but \( \mathcal{O}(1,2) \) cannot pass through the bundles in between, since there are non-vanishing Ext involved. We can avoid the problem using the fact that \( \hat{\mathcal{Q}}(1,1) \cong \hat{\mathcal{Q}}^\vee(1,2) \) and that we can mutate this last bundle in \( \tilde{\mathcal{U}}^\vee(1,2) \) acting with \( \mathcal{O}(1,2) \), due to the dual formulation of Lemma 5.4.

Again, all these operations can be performed twice:

\[ D^b(M) = \langle \mathcal{O}(1,1), \mathcal{Q}(0,2), \mathcal{Q}(1,3), \mathcal{O}(1,2), \mathcal{O}(0,3), \mathcal{O}(0,4), \hat{\mathcal{Q}}(0,4), \hat{\mathcal{U}}^\vee(1,2), \hat{\mathcal{Q}}(1,2), \mathcal{O}(1,3), \mathcal{O}(2,2), \mathcal{Q}(1,3), \mathcal{O}(1,4), \mathcal{O}(2,3), \mathcal{Q}(1,4), \mathcal{O}(1,5), \hat{\mathcal{Q}}(1,5), \hat{\mathcal{U}}^\vee(2,3), \hat{\mathcal{Q}}(2,3), \mathcal{O}(2,4), \phi_1 D^bY \rangle . \]

Now, \( \mathcal{O}(0,3) \) and \( \hat{\mathcal{U}}^\vee(1,2) \) qualify for a mutation of the type described in Lemma 5.5, to get them closer to each other we observe that, due to Lemma 5.2, the Ext between \( \mathcal{O}(0,3) \) and \( \mathcal{O}(1,2) \) vanishes, and, for a similar application of Borel–Weil–Bott theorem, also the Exts between \( \hat{\mathcal{U}}^\vee(1,2) \) and the two bundles at its left are zero. Applying the same sequence of mutations to the \( (1,1) \)-twist of these objects we get the following collection:

\[ D^b(M) = \langle \mathcal{O}(1,1), \mathcal{Q}(0,2), \mathcal{Q}(1,3), \mathcal{O}(1,2), \mathcal{U}(0,3), \hat{\mathcal{U}}^\vee(1,2), \mathcal{O}(0,3), \mathcal{O}(0,4), \hat{\mathcal{Q}}(0,4), \hat{\mathcal{Q}}(1,2), \mathcal{O}(1,3), \mathcal{O}(2,2), \mathcal{Q}(1,3), \mathcal{O}(1,4), \mathcal{U}(1,4), \hat{\mathcal{U}}^\vee(2,3), \mathcal{O}(1,4), \mathcal{O}(1,5), \hat{\mathcal{Q}}(1,5), \hat{\mathcal{Q}}(2,3), \mathcal{O}(2,4), \phi_1 D^bY \rangle . \]

Again, thanks to the dual formulation of Lemma 5.4, \( \mathcal{O}(1,3) \) can mutate \( \hat{\mathcal{Q}}(1,2) \) to \( \hat{\mathcal{U}}^\vee(1,3) \), so we can apply Lemma 5.5 to transform \( \hat{\mathcal{Q}}(0,4) \) in \( \mathcal{Q}(0,4) \). But then \( \mathcal{O}(1,3) \) ends up next to \( \mathcal{O}(0,4) \), which is orthogonal to it by application of Lemma 5.2, so they can be exchanged. Passing through \( \mathcal{Q}(0,4) \) via Lemma 5.4 and mutating it to \( \mathcal{U}(0,4) \), \( \mathcal{O}(0,4) \) goes right next to \( \hat{\mathcal{U}}^\vee(1,3) \), which is mutated to \( \mathcal{U}^\vee(1,3) \) by applying Lemma 5.5.

Once we have done the same for the \( (1,1) \)-twists, we have transformed all the rank 2 and rank 3 vector bundles on \( G(3, V_5) \) in vector bundles on \( G(2, V_5) \). What we still need to do is to remove the twists involving powers of the hyperplane class of \( G(3, V_5) \) and, consequently, recognize an exceptional collection of \( G(2, V_5) \) and its twist. Removing all the duals we get the following result:

\[ D^b(M) = \langle \mathcal{O}(1,1), \mathcal{Q}(0,2), \mathcal{O}(1,2), \mathcal{U}(0,3), \mathcal{U}(2,2), \mathcal{O}(0,3), \mathcal{O}(1,3), \mathcal{U}(0,4), \mathcal{U}(2,3), \mathcal{O}(0,4), \mathcal{O}(2,2), \mathcal{Q}(1,3), \mathcal{U}(1,4), \mathcal{U}(3,3), \mathcal{O}(1,4), \mathcal{O}(2,4), \mathcal{U}(1,5), \mathcal{U}(3,4), \mathcal{O}(1,5), \phi_1 D^bY \rangle . \]

First we send \( \mathcal{O}(1,1) \) to the end, then we use Lemma 5.3 to order the bundles by their power of the second twist:

\[ D^b(M) = \langle \mathcal{Q}(0,2), \mathcal{O}(1,2), \mathcal{U}(2,2), \mathcal{O}(2,2), \mathcal{U}(0,3), \mathcal{O}(0,3), \mathcal{O}(1,3), \mathcal{U}(2,3), \mathcal{Q}(1,3), \mathcal{O}(2,3), \mathcal{U}(3,3), \mathcal{O}(3,3), \mathcal{U}(0,4), \mathcal{O}(0,4), \mathcal{U}(1,4), \mathcal{O}(1,4), \mathcal{O}(2,4), \mathcal{U}(3,4), \mathcal{U}(1,5), \mathcal{O}(1,5), \phi_2 D^bY \rangle \]

where we defined

\[(48) \quad \phi_2 = R_{\mathcal{O}(3,3)} \circ \phi_1.\]
Now we send the last 10 objects to the beginning and reorder again the collection with respect to the second twist, obtaining the following:

\[
D^b(M) = \\
\langle U(1,1), O(1,1), U(-2,2), O(-2,2), U(-1,2), O(-1,2), O(0,2), U(1,2), Q(0,2), O(1,2), \\
U(2,2), O(2,2) U(-1,3), O(-1,3), U(0,3), O(0,3), O(1,3), U(2,3), Q(1,3), O(2,3), \phi_3 D^b Y \rangle,
\]

where

\[
\phi_3 = L_{U(3,3),O(3,3) U(0,4), O(0,4), U(1,4), O(1,4), O(2,4), U(3,4), U(1,5), O(1,5)} \circ \phi_2
\]

Now we observe that \(Q(0,2)\) is orthogonal to \(U(1,2)\), so they can be exchanged: this allows us to mutate \(Q(0,2)\) to \(U(0,2)\) sending it one step to the left. After doing the same thing with \(O(1,1)\)–twists of these bundles, the last steps are tensoring everything with \(O(-2, -2)\) and sending the first two bundles to the end.

We get:

\[
D^b(M) = \\
\langle U(-4,0), O(-4,0), U(-3,0), O(-3,0), U(-2,0), O(-2,0), U(-1,0), O(-1,0), U(0,0), O(0,0), \\
U(-3,1), O(-3,1), U(-2,1), O(-2,1), U(-1,1), O(-1,1), U(0,1), O(0,1), U(1,1), O(1,1), \phi_4 D^b Y \rangle
\]

We defined the last functor

\[
\phi_4 = T(-2, -2) \circ R_{U(1,1), O(1,1)} \circ \phi_3
\]

where \(T(-2, -2)\) is the twist with \(O(-2, -2)\).

Now, if we observe the first half of the collection, we can recognize \(D^b G(2, V_5)\): in fact, if we take the Kuznetsov collection (34), we can transform \(U\) to \(U^\vee(-1)\) in every Lefschetz block. Then, acting repeatedly with the canonical bundle to send object from the end to the beginning of the collection, we get our result, once we define \(\Phi \circ \pi_2^* = \phi_4\).

We have shown that both \(D^b(X)\) and \(\phi_4 D^b (Y)\) can figure as the last block of the first row in (32), so, for the uniqueness of the orthogonal complement, there is an equivalence of categories

\[
D^b(X) \rightarrow \phi_4 D^b(Y)
\]

Moreover, it is a known fact that the left and the right mutations define an action of the braid group on the set of exceptional collections: the right mutation provides an inverse for the left mutation, as explained, for example, in [HIV] and [Shi]. Thus we deduce that the categories \(D^b(Y)\) and \(\phi_4 D^b(Y)\) are equivalent.

Summing all up, the content of this section provides a proof for the following theorem:

**Theorem 5.7.** Let \(X\) and \(Y\) be dual Calabi–Yau threefolds in the sense of Definition 2.4. Then they are derived equivalent.

### 6. The GLSM construction

In this final section we will give a GLSM realization of dual pairs \((X,Y)\) of Calabi–Yau threefolds in \(\mathbb{A}_{25}\). Namely, we will construct a gauged linear sigma model with two Calabi–Yau phases associated to different chambers of the space of the stability parameter such that the critical loci are dual threefolds \(Y\) and \(X\).

The mathematical description of the GLSM we will use throughout this work is due to Okonek, to whom we are very thankful for his insights, while a thorough exposition of the subject has been given by Fan, Jarvis and Ruan in [FJR]. In their work, as an example, a similar construction of the Grassmannman \(G(k, n)\) as a GIT quotient with respect to \(GL(k, \mathbb{C})\) has been constructed, and the GLSM of a section of \(\bigoplus_j O(d_j)\) has been investigated, giving a formal definition of the critical loci in both the phases appearing in the model.
Definition 6.1. Let $V$ be a vector space endowed with the action of a reductive group $G$. We call \textit{gauged linear sigma model} the data of a $G$-invariant function
\begin{equation}
V \overset{w}{\longrightarrow} \mathbb{C}.
\end{equation}
called \textit{superpotential}. Furthermore, we define \textit{critical locus} associated to the superpotential $w$ the following variety:
\begin{equation}
\text{Crit}(w) = Z(dw).
\end{equation}
Fixed a character
\begin{equation}
G \overset{\rho}{\longrightarrow} \mathbb{C}^*
\end{equation}
the notion of semistability
\begin{equation}
V_{\rho}^{ss} = \{ v \in V : \{(\rho^{-1}g, gv)|g \in G\} \cap \{0\} \times V = \emptyset \}
\end{equation}
allows us to define the \textit{vacuum manifold} as a GIT quotient:
\begin{equation}
\mathcal{M}_\rho = \text{Crit}(w) \sslash \rho G.
\end{equation}
The notion of phase transition is encoded in the variation of stability conditions: namely, changing the character $\rho$ leads to different vacuum manifolds. According to the theory of stability conditions, the regions of the space of characters characterized by the same GIT quotients are called \textit{chambers}, thus the problem of phase transitions of a GLSM is interpreted as a problem of wall crossing.

Example 6.2. Let $G$ be a reductive group, $E = \mathcal{P} \times_G \mathcal{F}$ a vector bundle with base $B = \mathcal{P}/G$ and $s \in H^0(B, E)$. Given a $G$-module $U$ containing $\mathcal{P}$ with $\text{codim}_U(U \setminus \mathcal{P}) \geq 2$, we define the \textit{gauged linear sigma model} of $s$ to be a map
\begin{equation}
\mathcal{U} \times \mathcal{F}^\vee \overset{\hat{s}}{\longrightarrow} \mathbb{C}
\end{equation}
where the function
\begin{equation}
\hat{s} : \mathcal{U} \longrightarrow \mathcal{F}
\end{equation}
is completely defined by $s$, namely by the requirement of satisfying the $G$-equivariancy condition
\begin{equation}
s([p]) = [p, \hat{s}(p)].
\end{equation}
and, then, extended uniquely to $\mathcal{U}$, which is always possible as long as the above condition on the codimension is fulfilled.

By assumption there exists a character $\rho$ whose $G$-semistability condition on $\mathcal{U} \times \mathcal{F}^\vee$ has semistable locus $V_{\rho}^{ss} = \mathcal{P} \times \mathcal{F}^\vee$. In this case, the critical locus of the superpotential will be determined by the following.

Lemma 6.3 (Okonek’s lemma). Let $\hat{s}$ be a superpotential defined by a regular section $s \in H^0(B, E)$. Then the following isomorphism holds:
\begin{equation}
\text{Crit}(\hat{s}) \cong Z(\hat{s}).
\end{equation}
Proof. By definition, we have
\begin{equation}
Z(d\hat{s}) = \{(u, \lambda) \in \mathcal{E}^\vee : \hat{s}(u) = 0, \lambda \cdot d\hat{s}(u) = 0\}.
\end{equation}
Since $s$ is a regular section, then $\hat{s}$ is regular. Then, since its Jacobian $d\hat{s}$ has maximal rank, $\lambda \cdot d\hat{s}(u) = 0$ if and only if $\lambda = 0$. \hfill \Box
Then the vacuum manifold will be the GIT quotient of the zero locus of \( \hat{s} \) with respect to \( G \). This, in turn, gives

\[
\mathcal{M}_{\rho_0} = Z(s).
\]

We observe that this construction can be used to realize the zero locus of a section of a homogeneous vector bundle as a phase of a GLSM, provided a family of characters such that the GIT quotient with respect to a given chamber yields the right subset of the vector space \( U \times F^\vee \).

Varying the character \( \rho \) leads to different semistable loci, which, in turn, define different GIT quotients. These are called phases of the physical theory. An interesting physical problem is to discuss phase transitions of a gauged linear sigma model, which means wall-crossing between different chambers.

In the following, we will present our GLSM construction leading to the varieties discussed above. First, we will give the following characterization of the bundle \( U(2) \) over \( G(3, V_5) \):

\[
U(2) = \frac{\text{Hom}(C^3, V_5) \backslash \{ \text{rk} < 3 \} \times C^3}{G_{L(3, C)}} \ni (B, v) \sim (Bg^{-1}, \det g^{-2}gv)
\]

\[
G(3, V_5) = \frac{\text{Hom}(C^3, V_5) \backslash \{ \text{rk} < 3 \}}{G_{L(3, C)}} \ni B \sim Bg^{-1}.
\]

In this setting, chosen a rank three \( 5 \times 3 \) matrix \( B \), the section \( s \) is defined by the following:

\[
s(B) = (B, \hat{s}_1(B)b_1 + s_2(B)b_2 + s_3(B)b_3),
\]

where \( b_i \) are the three columns of \( B \). Thus, in order to respect the expected degree, \( \hat{s} \) must be a vector of three quintics in the entries of \( B \). In this way we have defined the image of \( s \) in \( V_5 \otimes O(2) \). In particular, since \( U(2) = (\pi_2)_* O(1, 1) \), the quintics \( \hat{s}_i(B) \) will be such that the second coordinate in (64) will be a vector of five polynomials which are quadratic in the \( 3 \times 3 \) minors of \( B \). Moreover, we see that \( s \) extends to a map

\[
\text{Hom}(C^3, V_5) \xrightarrow{s} \text{Hom}(C^3, V_5) \times C^3
\]

\[
B \quad \mapsto \quad (B, \hat{s}(B)).
\]

From the definition of \( \hat{s} \) we construct the following superpotential:

\[
\text{Hom}(C^3, V_5) \times (C^3)^\vee \xrightarrow{s} C
\]

\[
B, \omega \quad \mapsto \quad \omega \cdot \hat{s}(B)
\]

Note that this formulation of a GLSM fits into the physical description of [HTo]. In particular, the choice of a superpotential of the form given by [HTo, (2.6)] can be written, in physical terms, as

\[
W = \int d^2 \theta \text{Tr}(PB\hat{s}(B)),
\]

where \( \omega = PB \) and \( P_1, \ldots, P_5 \) are superfields transforming as \( P \mapsto \det g^2 P \) under the gauge group, which is \( U(3) \), and the integration is on two fermionic coordinates of the superspace.

Now, let \( \rho_\tau \) be the character defined by \( \rho_\tau(g) = \det g^{-\tau} \). This leads to two different chambers in the space of stability conditions.
6.0.1. The chamber $\tau > 0$. A pair $(B, \omega)$ is stable if there are no sequences \( \{g_n\} \) satisfying
\[
\lim_{n \to \infty} \det g_n = 0
\]
such that the sequence \( \{(Bg_n^{-1}, \det(g_n)^2 \omega g_n^{-1})\} \) has a limit. We observe that the term \( Bg_n^{-1} \) will always diverge in the limit, unless \( B \) has not maximal rank. In this latter case, it will be possible to choose a sequence \( g_n \) such that \( g_n^{-1} \) has no limit, but \( Bg_n^{-1} \) is finite. Since \( \det(g_n)^2 \omega g_n^{-1} \) is always finite, we get no further condition on \( \omega \).

Thus the GIT quotient relative to the chamber $\tau > 0$ will define the bundle $U'(\mathbb{C}^\ell)$ over $G(3, V_5)$ and the vacuum manifold, due to Lemma 6.3, is isomorphic to the Calabi–Yau threefold $Y = Z(s)$. Moreover, being the superpotential \( s \) $G$-invariant, the map \( s_+ \) in Diagram (69) is well defined:

\[
\begin{array}{ccc}
U'(\mathbb{C}^\ell) & \xrightarrow{s_+} & \mathbb{C} \\
Z(s) \subset G(3, V_5) & \longrightarrow & G(3, V_5). \\
\end{array}
\]

6.0.2. The chamber $\tau < 0$. Here, in order to achieve semistability, we need to test our pairs \( (B, \omega) \) with sequences \( g_n \), where \( \det g_n \) tends to infinity. In this setting, we claim that the semistable locus is given by the following set:
\[
V^{ss} = \{(B, \omega) \in \text{Hom}(\mathbb{C}^3, V_5) \times (\mathbb{C}^\ell)^3 : \omega \neq 0, \ker \omega \cap \ker B = 0\}.
\]

First of all, the case \( \omega = 0 \) is ruled out by the fact that there always exist a sequence \( \{g_n\} \) with \( \det g_n \to \infty \) such that \( (Bg_n^{-1}, 0) \) has a limit. Thus, let us suppose \( \omega \neq 0 \). To show that the set described in (70) contains the semistable locus, let us suppose \( \ker \omega \cap \ker B = 0 \) is non trivial. Then we fix a basis of \( V_5 \) and \( \mathbb{C}^3 \), where
\[
B = \begin{pmatrix}
0 & b_{12} & b_{13} \\
0 & b_{22} & b_{23} \\
0 & b_{32} & b_{33}
\end{pmatrix}, \quad \omega = \begin{pmatrix}
0 \\
\omega_2 \\
\omega_3
\end{pmatrix}.
\]

We can then exhibit a sequence \( \{g_n\} \), with \( \det g_n = n \), such that both \( \omega \) and \( B \) are fixed under its action. This is achieved, for example, with
\[
g_n^{-1} = \begin{pmatrix}
n^3 & 0 & 0 \\
0 & 1/n^2 & 0 \\
0 & 0 & 1/n^2
\end{pmatrix}.
\]

To prove the other inclusion, we must show that, if \( \ker \omega \cap \ker B = 0 \), there is no sequence \( \{g_n\} \) with \( \det g_n \to \infty \) such that the sequence \( g_n \cdot (B, \omega) \) has a limit.

Again, we can fix a basis of \( V_5 \) in order to achieve
\[
B = \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & b_{33}
\end{pmatrix}, \quad \omega = \begin{pmatrix}
0 \\
0 \\
1
\end{pmatrix}.
\]

In that case we define \( (B_n, \omega_n) \) the pair \( g_n \cdot (B, \omega) \). Then we form \( M_n \) to be the \( 3 \times 3 \) matrix whose first two rows are the first two rows of \( B_n \) and the third row is \( \omega_n \). Then we note that
\[
\det M_n = \det g_n^2 \det g_n^{-1} = \det g_n \to \infty
\]
hence \( M_n \) has no limit, so neither does \( g_n \cdot (B, \omega) \).

We observe that, since \( \ker \omega \) is two-dimensional, the condition \( \ker \omega \cap \ker B = 0 \) implies \( \text{rk} B \geq 2 \), otherwise the kernels would intersect in a non trivial vector space.

The critical locus of our superpotential, in the phase \( \tau < 0 \), is described by the following equations in \( V^s_\ast \):

\[
Z(d\hat{s}) = \begin{cases} 
  \omega \cdot d\hat{s} = 0 \\ 
  \hat{s} = 0
\end{cases}
\]

The request of having \( \omega \neq 0 \) in the kernel of the transpose of \( d\hat{s} \) can be rephrased saying that the Jacobian of \( \hat{s} \) has a non-trivial kernel and this is not possible if \( B \) is maximal rank. This fact, combined with the condition \( \text{rk} B \geq 2 \), yields \( \text{rk} B = 2 \), which automatically satisfies \( \hat{s} = 0 \).

In the following we will determine the explicit expression for the functions \( \hat{s}(B) \) via the pushforward of the general expression of a hyperplane section of the flag. This determines uniquely a section of \( \mathcal{U}(2) \) on \( G(3, V_5) \) and we can read \( \hat{s}(B) \) by confronting the result with (64). We will adopt the convention of the summation of repeated indices in order to lighten the notation. Furthermore the square brackets encasing a set of indices will mean that a tensor is made antisymmetric with respect to permutation of those indices, namely

\[
T_{[i_1,...,i_k]} = \frac{1}{k!} \sum_{\sigma \in S_k} \epsilon_\sigma T_{\sigma(i_1)...\sigma(i_k)}
\]

where \( \epsilon_\sigma \) is the sign of the permutation \( \sigma \).

A general section \( S \in H^0(\mathcal{F}, \mathcal{O}(1, 1)) \) can be written in the following way:

\[
S(A, B) = S^{ijklm}_{ij}(B) \psi_{lm}(A),
\]

where \( A \) is the matrix given by a basis of a representative of a point in \( G(2, V_5) \), while \( B \) is the same for \( G(3, V_5) \), \( \psi_{lm}(A) \) is the \( 2 \times 2 \) minor of \( A \) obtained choosing the rows \( l \) and \( m \) and \( \psi_{ijk}(B) \) is the \( 3 \times 3 \) minor of \( B \) defined in the same way. Note that the functions \( \psi \) are, by definition, completely antisymmetric, thus \( S \) will be antisymmetric with respect to \((i,j,k)\) and \((l,m)\).

Let us choose a basis of \( V_5 \) such that \( A \) is given by the second and the third columns of \( B \). Thus we can use the linearity of \( \psi_{klm}(B) \) with respect to the variables \( b_{r1} \) and write \( S \) in the following ways:

\[
S(A, B) = S^{ijklm}_{ij}(A) b_{k1} \psi_{lm}(A);
\]

\[
S(A, B) = S^{ijklm}_{ijk}(B) \frac{\partial}{\partial b_{p1}} \psi_{plm}(B)
\]

From (77) we can write the pushforward \( s_1 \) of \( S \) to \( G(2, V_5) \): seeing \((b_{11}, \ldots, b_{51})\) as a vector in \( Q^2(A) \), the usual inner product in \( V_5 \) allows us to define, as an element of \( Q^{\vee}(2) \), the vector whose \( r \)-th component is

\[
s_{1,r} = S^{ijklm}_{ijkl} \frac{\partial}{\partial b_{r1}} \psi_{ij}(A) b_{k1} \psi_{lm}(A)
\]

\[
= S^{ijklm}_{ijkl} \psi_{ij}(A) \delta_{k1} \psi_{lm}(A)
\]
In a similar way, we can define from (78) a section $s_2$ of $U(2)$, if we note that \{\partial_{b_1}, \ldots, \partial_{b_5}\} define a basis of linear functionals on $U_{B(\partial)}$. We get:

$$s_2 = S^{ijklm} \psi_{ijkl}(B) \begin{pmatrix} \psi_{1lm}(B) \\ \psi_{2lm}(B) \\ \psi_{3lm}(B) \\ \psi_{4lm}(B) \\ \psi_{5lm}(B) \end{pmatrix}.$$  

In the description of the GLSM, we defined a section of $U(2)$ with the following expression:

$$s_2(B) = B, \ s_1(B) + s_2(B) + s_3(B) + s_4(B) + s_5(B).$$

Confronting the last equation with (80) leads us to write the following expression for $\hat{s}(B)$:

$$\hat{s}(B) = \hat{S}^{ijklm} \psi_{ijkl}(B) \partial_{b_{pr}} \psi_{plm}(B).$$

In the above, we wrote $\hat{s}$ as a function defined on Hom($\mathbb{C}^3, V_5$)\{rk < 3\} with values in $\mathbb{C}^3$, but we note that, as expected, it extends by zeros to a function on all Hom($\mathbb{C}^3, V_5$). Namely, if the rank of $B$ is smaller than three, all the $3 \times 3$ minors vanish, so $\hat{s}(B) = 0$. Then, by inspection, we see that $s_1$ is linear in the entries of the $i$-th column of $B$ and quadratic in the entries of the other two columns.

Now, since \text{rk}B = 2, let us choose a basis where the first column of $B$ vanishes. This reduces the system of 15 equations $\omega \cdot d\hat{s} = 0$ to five quartics. The overall factor $\omega_1$ appearing in each of them can be discarded since the choice of having $b_1 = 0$ and the condition $\ker B \cap \ker \omega = 0$ imply $\omega_1 \neq 0$. Moreover, since the five quartics are independent on the entries of $b_1$, they are quadrics with respect to the $2 \times 2$ minors of the matrix obtained discarding the first column from $B$. Summing all up, the critical locus for the phase $\tau < 0$ is given by

$$\text{Crit}(\hat{s}) = \{(B, \omega) : \ker B \cap \ker \omega = 0; \text{rk} B = 2, \partial_{b_1} \hat{s}_1 = 0\}.$$  

Finally, computing the derivatives of (82) with respect to the entries of the first column of $B$, we get

$$\frac{\partial}{\partial b_{p1}} \hat{s}_1(B) = \hat{S}^{ijklm} \psi_{ijkl}(A) \delta_{kql} \psi_{lm}(A)$$

which are exactly the quadrics appearing in (77).

So far, we got no conditions on $\omega$ except for $\omega_1 \neq 0$: the critical locus of the superpotential in the chamber $\tau < 0$ is a bundle $E$ over the zero locus of the five quadrics in $G(2, V_5)$. However, we still have a $GL(3, \mathbb{C})$-action on this bundle: a matrix $B$ with zeros in the first column is fixed by a stabilizer of $GL(3, \mathbb{C})$ given by matrices of the form

$$g_n^{-1} = \begin{pmatrix} a & b & c \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

with $a \neq 0$ and all the triples $(\omega_1, \omega_2, \omega_3)$ with nonvanishing $\omega_1$ lie in the same orbit with respect to this stabilizer, which acts freely on them. So the action is transitive and free. Quotienting $E$ with respect to the $GL(3, \mathbb{C})$-action, yields exactly the Calabi–Yau threefold $X$, this proves the compatibility of our GLSM construction with the description of diagram (3).
Acknowledgements. We would like to thank Atsushi Ito, John Christian Ottem and Paul Francis de Medeiros for clarifying discussions, and Shinnosuke Okawa for showing us the reference [IMOU2]. M. Rampazzo was supported by the PhD program at the University of Stavanger. M. Kapustka was supported by the project NCN 2013/10/E/ST1/00688.
