Abstract. The paper is concerned with the maximization of Laplace eigenvalues on surfaces of given volume with a Riemannian metric in a fixed conformal class. A significant progress on this problem has been recently achieved by Nadirashvili–Sire and Petrides using related, though different methods. In particular, it was shown that for a given \( k \), the maximum of the \( k \)-th Laplace eigenvalue in a conformal class on a surface is either attained on a metric which is smooth except possibly at a finite number of conical singularities, or it is attained in the limit while a “bubble tree” is formed on a surface. Geometrically, the bubble tree appearing in this setting can be viewed as a union of touching identical round spheres. We present another proof of this statement, developing the approach proposed by the second author and Y. Sire.

1. Introduction and main results

1.1. Conformally maximal metrics. Let \( M \) be a compact surface without boundary endowed with a Riemannian metric \( g \). The corresponding measure is denoted by \( dv_g \), and in what follows all integrations and functional spaces are considered with respect to this measure unless indicated otherwise. Let \( \Delta_g \) be the associated Laplace-Beltrami operator on \( M \) with eigenvalues

\[
0 = \lambda_0 < \lambda_1 \leq \lambda_2 \leq \ldots \lambda_n \ldots \nearrow +\infty
\]

and corresponding eigenfunctions \( \phi_n \), forming an orthonormal basis in \( L^2(M) \).

Given a conformal class \( \mathcal{C} \) of Riemannian metrics on \( M \), let

\[
\Lambda_k(M, \mathcal{C}) = \sup_{g \in \mathcal{C}} \lambda_k(M, g) \text{Area}(M, g).
\]

It is well-known that this supremum is always finite [Kor, Ha], and the numbers \( \Lambda_k(M, \mathcal{C}) \) are called the conformal spectrum of \( M \) (see [CES]). The goal of the present paper is to provide a new proof of the following result due to Nadirashvili–Sire and Petrides (see [NaSi1, NaSi2] and [Pet1, Pet3]):

Theorem 1.1. Let $M$ be a compact Riemannian surface without boundary.

(i) For any conformal class $C$ of Riemannian metrics on $M$, there exists a metric $g \in C$, possibly with a finite number of conical singularities, such that

$$(1.1.2) \quad \Lambda_1(M, C) = \lambda_1(M, g) \text{Area}(M, g).$$

(ii) For any conformal class $C$ of Riemannian metrics on $M$ and for any $k > 1$, either one has

$$(1.1.3) \quad \Lambda_k(M, C) = \Lambda_{k-1}(M, C) + 8\pi,$$

or there exists a metric $g \in C$, possibly with a finite number of conical singularities, such that

$$(1.1.4) \quad \Lambda_k(M, C) = \lambda_k(M, g) \text{Area}(M, g) > \Lambda_{k-1}(M) + 8\pi.$$

Remark 1.2. Applying part (ii) of Theorem 1.1 iteratively, we arrive at an alternative that could be informally stated as follows. Given $k > 1$, either there exists a maximal metric for $\lambda_k$ which is smooth outside a finite number of conical singularities, or the supremum $\Lambda_k(M, C)$ is achieved by a sequence of metrics degenerating (in a sense to be specified in Section 5) to a disjoint union of $1 < j < k$ identical round spheres of volume $8\pi/\Lambda_k(M, C)$ (so-called “bubbles”) and the surface $M$ endowed with a maximal metric for $\Lambda_{k-j}(M, C)$, which is smooth away from a finite number of conical singularities. Note that the number of conical singularities of a maximal metric for $\Lambda_k(M, C)$ is bounded above in terms of $k$ and the genus of $M$, see [Kar2, Proposition 1.13]. Let us also mention that equality (1.1.3) can be stated in such a simple form due to the results of [KNPP]. We note as well that if one replaces the strict inequality in (1.1.4) by a non-strict inequality, it would always be true by the standard gluing argument (see [CES, Theorem B] and [KNPP, Remark 2.4]).

Remark 1.3. Part (i) of Theorem 1.1 appeared first in [NaSi1] under the assumption

$$(1.1.5) \quad \Lambda_1(M, C) > 8\pi = \Lambda_1(S^2).$$

It was later shown in [Pet1] that this inequality holds for any conformal class $C$ on any surface $M$ which is not a sphere.

Remark 1.4. The exact values of $\Lambda_k(M, C)$ and the corresponding maximizing metrics are known in a very few cases. Apart from the results for the sphere [Na2, Pet2, NaSi3, KNPP] and for the real projective plane ([NaPe, Kar1]), nothing is known in the case $k > 1$. For $k = 1$, global maximizers (i.e. maximizers over all all conformal classes) have been found for the sphere [Her], the real projective plane [LY], the torus [Na1], the Klein bottle [JNP, EGJ, CKM] and the surface of genus two [JLNNP, NaSh]. It is also known that for certain conformal classes on tori, the first eigenvalue is maximized by the Euclidean metric [EIR]. Finally, let us note that for $k = 1$ the
analogue of part (i) of Theorem 1.1 for global maximizers has been recently proved in [MS].

Remark 1.5. It is remarked in [Pet3] that inequality (1.1.4) is expected to hold for some conformal classes. We provide the proof below. Consider a degenerating sequence $C_n$ of conformal classes of the genus 2 surface $\Sigma_2$, converging (on the Deligne-Mumford compactification of the moduli space) to two copies of the equilateral torus. Using the continuity result [KM, Theorem 2.8] one has that

$$\lim_{n \to \infty} \Lambda_2(\Sigma_2, C_n) \geq 2\Lambda_1(T^2, C_{eq}) = \frac{16\pi^2}{\sqrt{3}}.$$  

At the same time, $\Lambda_1(\Sigma_2, C_n) \leq 16\pi$ by the Yang-Yau inequality (which is in this case an equality, see [NaSh, JLNNP]). Since $\frac{16\pi^2}{\sqrt{3}} > 24\pi$, for large enough $n$ one has

$$\Lambda_2(\Sigma_2, C_n) > 24\pi \geq \Lambda_1(\Sigma_2, C_n) + 8\pi,$$

which is exactly inequality (1.1.4).

1.2. Plan of the proof. The methods used in [NaSi1, NaSi2] and [Pet1, Pet3] to prove Theorem 1.1 are different, though they share some common tools. The approach developed in [Pet1, Pet3] uses the heat equation techniques in an essential way. The argument outlined in [NaSi1, NaSi2] uses a reformulation of the eigenvalue optimisation problem in terms of Schrödinger operators (see also [GNS]). In this paper we present a proof of Theorem 1.1 developing the approach of [NaSi1, NaSi2]. We clarify some of the ideas that were put forward in those papers, and introduce several new ingredients which are needed to complete the argument.

Let us describe the main parts of the proof of Theorem 1.1. The first part essentially follows [NaSi1, GNS]. We start by fixing a metric $g \in \mathcal{C}$ on $M$ of constant curvature satisfying $\text{Area}_g(M) = 1$, and use the conformal invariance of $\Delta$ to reduce our consideration to a family of eigenvalue problems

$$\Delta u = \lambda V u,$$

where $V \in L^1(M)$ is a positive function with the unit $L^1$-norm. Geometrically, the potential $V$ (under an additional assumption $V \in C^\infty(M)$) represents the conformal factor for a metric $g' = Vg \in \mathcal{C}$, and the condition $||V||_1 = 1$ means that $\text{Area}_{g'}(M) = 1$. This leads to an optimisation problem $(A_k)$ defined in subsection 2.1. For the reasons explained below, we would like to consider the eigenvalue equation (1.2.1) for not necessarily positive functions $V$. However, in that case the corresponding spectral problem is not elliptic, since the quadratic form $Q(u, v) = \int_M V uv \, dv_g$ is no longer positive definite. In order to circumvent this difficulty we reformulate the problem (1.2.1) in terms of a certain Schrödinger operator, see subsection 2.2. Using this reformulation we introduce an optimisation problem $(B_k)$ which
is in a sense equivalent to \( (A_k) \). At the same time, it admits simpler extremality conditions, because it allows more general perturbations. This leads to Theorem 2.14 which states that for each \( k \geq 1 \), there exists a maximizing sequence \( N_m \) of (possibly singular) metrics defined by the potentials \( V_{N_m,k} \), such that the corresponding eigenfunctions \( \phi_{N_m,k} \) converge weakly in \( H^1 \). This brings us to the next step of the argument, because the weak convergence of eigenfunctions is not enough to deduce the required regularity properties of the limiting metric.

The second part of the proof is described in Section 4. We define the good points (see Definition 4.5), which are characterised by having a neighborhood with a sufficiently large first Dirichlet eigenvalue. In a way, this means that the measure does not concentrate too much near a good point; if this condition is violated, we say that a point is bad. Using variational arguments we show that all but possibly \( k \) points on \( M \) are good. The key technical result of Section 4 is Proposition 4.7 which shows that \( \phi_{N_m,k} \) converge strongly in \( H^1 \) in a neighborhood of a good point. We refer to Remark 4.8 for an interpretation of this result as an \( \varepsilon \)-regularity type theorem (see [CM]). The proof of Proposition 4.7 requires rather delicate auxiliary analytic results which are proved in Section 3 using the theory of capacities. Some of them, such as Lemma 3.9 could be of independent interest. Using Proposition 4.7 we prove Theorem 4.1 which is the main result of this section. It states that the limiting measure is regular away from bad points, while the latter give rise to \( \delta \)-measures, i.e. atoms. The regular part is constructed via a harmonic map defined using limiting eigenfunctions. The harmonic map theory (see [Hel, Kok2]) then yields that the regular part may have at most a finite number of conical singularities. Sections 3 and 4 contain probably the most novel ingredients of the proof of Theorem 1.1.

The last part of the proof is presented in Section 5. It describes the behaviour of a maximizing sequence of metrics near the atoms, and in a sense is a variation of the bubble tree construction for harmonic maps [Par]. A similar construction using somewhat different analytic tools could be also found in [Pet3]. This part of the proof is technically quite involved and could be subdivided into several steps. We choose a normalization parameter \( C_R \) that eventually will tend to zero, and rescale the metric near the bubble. The constant \( C_R \) determines the rescaling, and controls the size of the bubbles: in particular, we will ignore bubbles of size less than \( C_R \) (note that for each fixed \( k \), bubbles of sufficiently small size do not affect \( \lambda_k \)). In the process of rescaling, secondary bubbles (i.e. the descendants of the initial bubble on the bubble tree) may arise. However, we show in Lemma 5.5 that each time a secondary bubble appears, its size decreases in a controlled way and therefore the bubble tree is finite. Moreover, \( C_R \) controls the size of the necks, i.e. the areas between a bubble and its descendant on the bubble tree.
Using the rescaling and an inverse stereographic projection to the sphere, we view each bubble \( b \) as a sphere with a sequence \( \tilde{V}_{b}^{b_{N_{m,k}}} \) of metrics which are obtained from the maximizing sequence \( V_{N_{m,k}} \) described above. Away from the secondary bubbles, this sequence converges weakly to a limiting metric defined by a potential \( \tilde{V}_{\infty}^{b} \in L^{1}(S^{2}) \), see Theorem 5.6. If this potential is bounded, we say that the bubble is of type I, otherwise we say that the bubble \( b \) is of type II. In the latter case the Laplacian on \( S^{2} \) with the limiting metric defined by \( \tilde{V}_{\infty}^{b} \) may have essential spectrum, see Remark 5.8.

For type II bubbles the construction of the test-functions for the eigenvalue \( \lambda_{k} \) is significantly more involved than for type I bubbles, see subsection 5.2. In section 5.3 we estimate the Rayleigh quotients of test functions separately on different parts of the surface \( M \): the smooth part, the type I bubbles, the type II bubbles and necks. Taking \( C_{R} \to 0 \) and applying (1.1.5) together with [KNPP, Theorem 1.2], we complete the proof of Theorem 1.1.

Remark 1.6. The distinction between type I and type II bubbles is related to the validity of a certain relation between the choice of the rescaling and the choice of the maximizing subsequence \( N_{m,k} \), see (5.1.2). This difficulty appears to be intrinsic to the problem, as a similar issue arises in the bubble tree construction in [Pet3, Section 5].

2. Two optimisation problems

2.1. Optimisation of the eigenvalues in a conformal class. Consider the spectral problem (1.2.1) with \( V \geq 0 \). It can be understood in the weak form, where \( V \, dv_{g} \) is treated as a Radon probability measure (see [Kok2]). The eigenvalues of such a problem can be characterised variationally via Rayleigh quotient, i.e one defines

\[
\lambda_{k}(V) = \inf_{E_{k}} \sup_{u \in E_{k}} \frac{\int_{M} |\nabla u|^{2} \, dv_{g}}{\int_{M} V \, u^{2} \, dv_{g}},
\]

where the supremum is taken over \( E_{k} \subset C^{\infty}(M) \) which form \( (k+1) \)-dimensional subspaces in \( L^{2}(V \, dv_{g}) \). The latter condition is equivalent to saying that the restriction of \( E_{k} \) to \( \text{supp} \, V \) is \( (k+1) \)-dimensional. Note that we enumerate the eigenvalues starting from \( \lambda_{0}(V) \).

Remark 2.1. Alternatively, variational characterisation (2.1.1) could be written in the form

\[
\lambda_{k}(V) = \sup_{F_{k}} \inf_{u \perp F_{k}} \frac{\int_{M} |\nabla u|^{2} \, dv_{g}}{\int_{M} V \, u^{2} \, dv_{g}},
\]

where \( F_{k} \) is now \( k \)-dimensional and \( \perp \) is understood in \( L^{2}(V \, dv_{g}) \).
Let $\mathcal{N}(\lambda) = \#\{\lambda_i(V) < \lambda\}$ be the eigenvalue counting function. The following proposition holds.

**Proposition 2.2.** Let $Q^V_\lambda(u, v)$ be the following quadratic form

$$Q^V_\lambda(u) = \int_M |\nabla u|^2 dv_g - \lambda \int_M u^2 V dv_g.$$ 

Then $\mathcal{N}(\lambda) = \text{ind } Q^V_\lambda$, i.e. the right-hand side is defined as the maximal dimension of a linear subspace on which $Q^V_\lambda$ is negative definite.

**Proof.** Let us show first that $\text{ind } Q^V_\lambda \leq \mathcal{N}(\lambda)$. Suppose there exists a $k$-dimensional space $G_k$, where $Q^V_\lambda$ is negative definite. We will prove that $\lambda_{k-1}(V) < \lambda$, which implies $\mathcal{N}(\lambda) \geq k$. The first observation is that $G_k$ remains $k$-dimensional in $L^2(V dv_g)$. Indeed, if $u \in G_k$ is such that $\int_M u^2 V dv_g = 0$, then $Q^V_\lambda(u, u) \geq 0$. Thus we can use $G_k$ in the variational characterisation (2.1.1) for $\lambda_k$. The claim then follows, since for any $u \in G_k$ one has

$$\int_M |\nabla u|^2 dv_g < \lambda \int_M u V dv_g.$$ 

Let us now prove the inequality in the opposite direction: $\text{ind } Q^V_\lambda \geq \mathcal{N}(\lambda)$. Let $k = \mathcal{N}(\lambda) - 1$ and let $G_{k+1}$ be the $(k+1)$-dimensional space spanned by the first $k$ eigenfunctions and the constants (corresponding to $\lambda_0 = 0$). Then it is easy to see that $Q^V_\lambda$ is negative definite on $G_k$. This implies that $\text{ind } Q^V_\lambda = \mathcal{N}(\lambda)$ and completes the proof of the proposition. \[ \square \]

Consider the class of functions

$$L_N = \{V | V \in L^\infty(M), 0 \leq V \leq N, ||V||_1 = 1\}$$ 

endowed with *-weak topology coming from identity ($L^1)^* = L^\infty$. Since $L_N$ is bounded a subset of $L^\infty$, it is compact in this topology by Banach-Alaoglu theorem. Moreover, one has the following Proposition.

**Proposition 2.3.** [Kok2, Proposition 1.1] Functional $\lambda_k(V)$ is upper semi-continuous on $L_N$.

Consider the following optimisation problem:

$$(A_k) \quad \lambda_k(V) \to \max \quad \text{for } V \in L_N.$$ 

The following proposition holds:

**Proposition 2.4.** [Kor] There exists a universal constant $C$ such that for all $V \in L_N$ one has

$$\lambda_k(V) \leq Ck.$$ 

Propositions 2.3 and 2.4 combined imply that there exists a solution to problem $(A_k)$. Set

$$\tilde{\Lambda}_N^k = \max_{V \in L_N} \lambda_k(V).$$
Since any non-negative $L^\infty$ function can be approximated by positive $C^\infty$ function such that the Laplacian spectra converge, see [CKM, Lemma 4.5], one has
\begin{equation}
\lim_{N \to \infty} \tilde{\Lambda}_k^N = \Lambda_k(M, C).
\end{equation}

2.2. Negative eigenvalues of Schrödinger operator. Let $\Delta - W$ be the classical Schrödinger operator with $W \in L^\infty(M)$. Let $\sigma_k(W)$ denote the corresponding eigenvalues, i.e. real numbers $\sigma$ such that there exist a non-zero solution of
\begin{equation}
\Delta u - Wu = \sigma u.
\end{equation}

The eigenvalues $\sigma_k(W)$ admit a variational characterisation as follows,
\begin{equation}
\sigma_k(W) = \inf_{E_k} \sup_{u \in E_k} \frac{\int_M (|\nabla u|^2 - Wu^2) \, dv_g}{\int_M u^2 \, dv_g},
\end{equation}
where $E_k$ ranges over $(k+1)$-dimensional subspaces in $C^\infty(M)$.

Remark 2.5. We enumerate eigenvalues $\sigma_k$ starting from $k = 0$, similarly to the eigenvalues $\lambda_k$. Thus, $\sigma_k$ is in fact the $(k+1)$-st eigenvalue of the Schrödinger operator $\Delta - W$.

The following proposition is proved similarly to Proposition 2.2.

Proposition 2.6. Let $N_- = \#\{\sigma_i < 0\}$. Then $N_- = \text{ind} Q_1^W$.

Define the class of functions
\[ M_{N,k} = \{ W \in L^\infty(M), \, \sigma_k(W) \geq 0, \, ||W||_\infty \leq N \}. \]
It was shown in [GNS, Lemma 2.1] that $M_{N,k}$ is compact in *-weak topology.

The second optimisation problem is the following,
\begin{equation}
(B_k) \quad \int_M W \, dv_g \to \max \quad \text{for} \quad W \in M_{N,k}.
\end{equation}

This functional is obviously bounded by $N$, therefore there exist a solution to this problem.

The following theorem essentially states that problems $(A_k)$ and $(B_k)$ are equivalent in the limit $N \to \infty$.

Theorem 2.7. Let $\{W_{N,k}\}_N$ be a sequence of solutions to $(B_k)$ for $k \geq 1$. Set
\[ V_{N,k} = \frac{W_{N,k}}{\int_M W_{N,k} \, dv_g}. \]
Then for sufficiently large $N$ one has
(i) $V_{N,k} \geq 0$ almost everywhere;
(ii) $\lambda_k(V_{N,k}) = \int_M W_{N,k} \, dv_g$;
(iii) $\limsup_{N \to +\infty} \lambda_k(V_{N,k}) = \Lambda_k(M, C)$. 

Let us first explain the significance of this result. As we will see below the extremality condition for the problem \((B_k)\) is more tractable than the corresponding condition for \((A_k)\). It is a consequence of the fact that the space \(\mathcal{M}_{N,k}\) contains functions which may take negative values, i.e. there is more freedom in choosing a perturbation.

**Proof.** The main part of the proof of this theorem is contained in [GNS]. In particular, in [GNS Lemma 3.1] it is shown that for large enough \(N\), the solution \(W_{N,k}\) is non-negative almost everywhere (see also Remark 2.8), and in [GNS Lemma 2.2] it is proved that \(\sigma_k(W_{N,k}) = 0\).

**Proof of (i).** Since \(W_{N,k} \geq 0\) almost everywhere, it is sufficient to show that \(W_{N,k} \not\equiv 0\) as an element of \(L^\infty(M)\). But then for each \(0 < c < \lambda_1(M,g)\) the constant function \(c \in \mathcal{M}_{N,k}\) and therefore \(W_{N,k} \equiv c\) can not be a solution to \((B_k)\).

**Proof of (ii).** Note that for \(\lambda = \int_M W_{N,k} \, dv_g\) the eigenvalue equation \((\Delta - \lambda V_{N,k})u = 0\) coincides with the equation for the zero eigenvalue of the operator \(\Delta - W_{N,k}\). In particular, the multiplicity of \(\lambda\) as an eigenvalue of the first equation equals the multiplicity of 0 as the eigenvalue of the second. Moreover, by Propositions 2.2 and 2.6 one has \(N(\lambda) = N_-\). As a result, we have that \(\lambda\)-eigenvalues of the first equation have the same indices as 0-eigenvalues of the second. Since \(\sigma_k(W_{N,k}) = 0\), then \(\lambda_k(V_{N,k}) = \lambda\).

**Proof of (iii).** Let \(\tilde{V}_{N,k} \in \mathcal{L}_N\) be a solution to \((A_k)\): \(\lambda_k(\tilde{V}_{N,k}) = \Lambda_N^N\). Set \(\tilde{W}_{N,k} = \lambda_k(\tilde{V}_{N,k})\tilde{V}_{N,k}\). Then \(\tilde{W}_{N,k} \in \mathcal{M}_{\tilde{N},k}\) for \(\tilde{N} = \lambda_k(\tilde{V}_{N,k}) N + 1\). Then by (ii) we have

\[
(2.2.3) \quad \lambda_k(V_{N,k}) = \int_M W_{N,k} \, dv_g \geq \int_M \tilde{W}_{N,k} \, dv_g = \lambda_k(\tilde{V}_{N,k}) = \Lambda_N^N,
\]

where the inequality in the middle follows from the fact that \(W_{N,k}\) is a solution of \((B_k)\) in \(\mathcal{M}_{\tilde{N},k}\). Note that the right-hand side of (2.2.3) converges to \(\Lambda_k(M,C)\) by (2.1.3), which implies \(\limsup_{N \to +\infty} \lambda_k(V_{N,k}) = \Lambda_k(M,C)\).

**Remark 2.8.** Let us remark that the statement of [GNS Lemma 3.3] that is used in the proof [GNS Lemma 3.1] contains a minor inaccuracy. It requires the solution \(v\) to be \(C^2\), whereas in the sequel Lemma 3.3 is applied to eigenfunctions of a Schrödinger operator with \(L^\infty\) potential, which are Hölder continuous (see, for instance, [Kok1]), but not necessarily \(C^2\). However, this is not a problem, since Lemma 3.3 holds for a wider class of solutions. In particular, the proof presented in [GNS] remains valid under the assumption that \(v \in H^1 \cap C^0\) is a weak solution of [GNS inequality (7)].

In the following we use \(V_{N,k}\) as a maximizing sequence for \(\Lambda_k\) and assume \(N\) is large enough so that Theorem 2.7 holds. We also set

\[
(2.2.4) \quad \Lambda_k^N := \lambda_k(V_{N,k}) = \int_M W_{N,k} \, dv_g.
\]
2.3. Extremality conditions for problem \((B_k)\). The reason we chose the maximizing sequence in this way is that the extremality condition for problem \((B_k)\) has a particularly convenient form which we derive below. We will use the following well-known lemma (see [GNS, Lemma 3.2], see also [Kat, Theorem 2.6, section 8.2.3]).

**Lemma 2.9.** Let \(W(t, x)\) be a function on \(\mathbb{R} \times M\) such that for any \(t \in \mathbb{R}\), \(W(t, \cdot) \in L^\infty(M)\) and \(\partial_t W(t, \cdot) \in L^\infty(M)\). For any \(t \in \mathbb{R}\) consider the eigenvalue problem
\[
\Delta u - W(t, \cdot)u = \sigma(t)u
\]
Denote by \(\{\sigma_l(t)\}\) the sequence of the eigenvalues counted with multiplicity and arranged in increasing order. Suppose that
\[
\sigma_{l-1}(0) < \sigma = \sigma_l(0) = \ldots = \sigma_{l+m-1}(0) < \sigma_{l+m}(0).
\]
Let \(U_\sigma\) be the eigenspace for \(t = 0\) corresponding to \(\sigma\). Define a bilinear form \(Q\) on \(U_\sigma\) by
\[
Q(u, v) = -\int_M \partial_t W(0, \cdot)uv \, dv_g
\]
and denote by \(\alpha_i, i = 0, \ldots, m-1\) the eigenvalues of this form with respect to the \(L^2\) inner product, counted with multiplicity and arranged in an increasing order. Then for any \(i = 0, \ldots, m-1\), we have
\[
\sigma_{l+i}(t) = \sigma_{l+i}(0) + t\alpha_i + o(t)
\]
For an element of the maximising sequence \(V_{N,k}\) let \(U_{N,k}\) to be the eigenspace corresponding to \(\Lambda_{N,k}\). Note that \(U_{N,k}\) is also 0-eigenspace for the problem \((2.2.1)\) with \(W = W_{N,k} := \Lambda_{N,k} V_{N,k}\). By definition \(0 \leq W_{N,k} \leq N\). Set
\[
E_{N,k} = \left\{ x \in M \mid W_{N,k}(x) \geq \frac{N}{2} \right\}.
\]

**Proposition 2.10.** For any \(v \in L^\infty(M)\) such that \(\int_M v = 0\) and \(v \leq 0\) on \(E_{N,k}\), there exists \(u \in U_{N,k}\) \(\{0\}\) such that \(\int_M vu^2 \geq 0\).

**Proof.** Assume the contrary, i.e. there exists \(v \in L^\infty\) such that \(\int_M v = 0\); \(v \leq 0\) on \(E_{N,k}\) and for all \(u \in U_{N,k}\) \(\{0\}\) one has
\[
\int_M vu^2 \, dv_g < 0.
\]
Set \(W(t) = W_{N,k} + tv\). We first remark that in view of \((2.3.4)\), the quadratic form \((2.3.1)\) is positive definite, and therefore by \((2.3.2)\) one has
\[
\sigma_k(W(t)) > \sigma_k(W(0)) = 0
\]
for \(1 \gg t > 0\).
 Furthermore, we claim that $W(t) \in \mathcal{M}_{N,k}$ for $1 \gg t > 0$. Indeed, on $E_{N,k}$ one has $v \leq 0$ and $\frac{N}{2} \leq W_{N,k} < N$. Therefore,

$$-N \leq \frac{N}{2} + tv \leq W_{N,k} + tv \leq N$$

for $1 \gg t > 0$. At the same time, on $M \setminus E_{N,k}$ we have $0 \leq W_{N,k} < \frac{N}{2}$, and hence

$$-N \leq tv \leq W_{N,k} + tv \leq \frac{N}{2} + tv \leq N$$

for $1 \gg t > 0$.

Thus, $W(t) \in \mathcal{M}_{N,k}$ and $\int_M W(t) = \int_M W_{N,k}$, i.e. $W(t)$ is a solution to $(\mathcal{B}_k)$. Recall that by [GNS, Lemma 2.2], any solution to $(\mathcal{B}_k)$ has to satisfy $\sigma_k(W(t)) = 0$ and we arrive at a contradiction with (2.3.5). □

Proposition 2.10 allows us to obtain the following characterisation of solutions to $(\mathcal{B}_k)$.

**Proposition 2.11.** There exists a collection $\phi_{N,k} = (u^1_{N,k}, \ldots, u^{\ell(N)}_{N,k})$ of elements of $U_{N,k}$ such that $|\phi_{N,k}|^2 = \sum_{i=1}^{\ell(N)} (u^i_{N,k})^2 = 1$ on $M \setminus E_{N,k}$, $dv_g$–a.e., and $w_{N,k} \leq 1$, $dv_g$–a.e.

The proposition is an easy corollary of the lemma below.

**Lemma 2.12.** Let $E \subset M$ be a measurable set in $M$. Let $Q$ be a convex finite-dimensional cone in $L^1(M)$ such that

(i) If $q \in Q$ then $q \geq 0$ a.e.

(ii) For any $v \in L^\infty(M)$ such that $\int_M v = 0$ and $v \leq 0$ a.e. on $E$ there exists $0 \neq q \in Q$ such that $\int_M v q \geq 0$.

Then there exists $q_0 \in Q$ such that $q_0 \equiv 1$ on $M \setminus E$ and $q_0 \leq 1$ a.e.

**Proof.** The proof of this lemma is inspired by [Na1, Theorem 5], [NaSi1, Lemma 3.8]. Denote by $K$ the following convex cone

$$K = \{u \in L^1(M) | u \equiv 0 \text{ on } M \setminus E, u \leq 0 \text{ a.e. on } E\}.$$  

First, we note that $K \cap Q = \{0\}$. Indeed, any $u \in K \cap Q$ satisfies $u \geq 0$ a.e. and $\int_M u \leq 0$ at the same time. Let $K_1$ be the convex cone spanned by $1$ and $K$. Suppose that $Q \cap K_1 \neq \{0\}$. Then there exists $0 \neq q \in Q$, $\alpha \geq 0$ and $k \in K$ such that $q = \alpha + k$. Since $K \cap Q = \{0\}$, one has that $\alpha \neq 0$. Therefore, $q_0 = \alpha^{-1}q$ satisfies the conditions of the lemma.

In the rest of the argument we assume the contrary, i.e. that $K_1 \cap Q = \{0\}$. According to a Hahn–Banach type result [Kl, Theorem 2.7], there exists an element $v_0 \in (L^1)^*(M) = L^\infty(M)$ such that for any $k_1 \in K_1 \setminus \{0\}$ and any $q \in Q \setminus \{0\}$ one has

$$\int_M v_0 k_1 > 0 > \int_M v_0 q.$$
Set $v = v_0 - \int_M v_0$ so that

\begin{equation}
\int_M v = 0.
\end{equation}

Our goal is to show that $v$ contradicts property (ii) of the cone $Q$.

First, note that for any $0 \neq q \in Q$ one has

\begin{equation}
\int_M qv < 0.
\end{equation}

Indeed, since $1 \in K_1$, in view of the first inequality in (2.3.7) one has

\begin{equation}
\int_M v_0 > 0.
\end{equation}

Therefore,

\begin{equation}
\int_M qv = \int_M qv_0 - \int_M q\int_M v_0 < 0.
\end{equation}

Note that the first term is negative by the second inequality in (2.3.7), and both integrals in the second term are nonnegative due to (2.3.10) and property (i) of the cone $Q$.

Second, let us show that for any $0 \neq k \in K$ one has

\begin{equation}
\int_M vk > 0.
\end{equation}

Indeed, since $\int_M k \leq 0$ by (2.3.6), one has $k - \int k \in K_1$. Therefore, by the first inequality in (2.3.10) we have

\[ 0 < \int_M v_0 \left( k - \int_M k \right) = \int_M v_0 k - \int_M v_0 \int_M k = \int_M vk. \]

Now, take $F = \{x \in E, v(x) > 0\}$ and let $\chi_F$ be the characteristic function of $F$. Then $-\chi_F \in K$ and one has

\[ 0 \leq -\int_M v\chi_F \leq 0, \]

where the first inequality follows from (2.3.11) and the second inequality is trivial. Therefore, both inequalities are equalities, which is possible iff $\text{Area}(F) = 0$. Therefore, $v \leq 0$ a.e. on $E$. Together with (2.3.8) it means that $v$ satisfies the assumptions in property (ii) of the cone $Q$, and we get a contradiction with (2.3.9). This completes the proof of the lemma. \hfill \Box

**Proof of Proposition 2.11.** In Lemma 2.12, let $Q$ be the convex hull of the squares of elements in $U_{N,k}$ and let $E := E_{N,k}$. Note that property (ii) of $Q$ follows from Proposition 2.10 and property (i) is immediate. The result then follows by a direct application of Lemma 2.12. \hfill \Box

**Proposition 2.11.** There exists a constant $C$ such that for any $k, N \in \mathbb{N}$ and any $i = 1, \ldots, l(N)$, we have $\|u_{N,m,k}^i\|_{H^1} \leq Ck$. 

**Corollary 2.13.** There exists a constant $C$ such that for any $k, N \in \mathbb{N}$ and any $i = 1, \ldots, l(N)$, we have $\|u_{N,m,k}^i\|_{H^1} \leq Ck$. 

Proof. Indeed, it follows from Proposition 2.11 that the $L^2$ norm of $u_{N,m,k}^i$ is bounded above by a constant equal to $\text{Area}(M)$. At the same time, the Dirichlet energy of $u_{N,m,k}^i$ is bounded by $Ck$ by Proposition 2.4. This completes the proof of the corollary. □

For future reference, let us summarize the results of this section in the following theorem.

Theorem 2.14. For each $k \geq 1$, there exists a strictly increasing sequence $N_m, m = 1, 2, \ldots$, of natural numbers, and maps $\phi_{N,m,k} = (u_{N,m,k}^1, \ldots, u_{N,m,k}^d) : M \to \mathbb{R}^d$ for some $d \in \mathbb{N}$, such that

1. $\Delta \phi_{N,m,k} = \Lambda_{2N,m,k} V_{N,m,k} \phi_{N,m,k}$.
2. The $(k + 1)$-st eigenvalue of the Schrödinger operator $\Delta - \Lambda_{2N,m,k} V_{N,m,k}$ is zero.
3. $\|V_{N,m,k}\|_{L^\infty} \leq CN_m$, $\|V_{N,m,k}\|_{L^1} = 1$.
4. There exists a weak limit $\phi_{N,m,k} \rightharpoonup \phi_k = (u_1^k, \ldots, u_d^k)$ in $H^1$ and $\phi_{N,m,k} \to \phi_k$ in $L^2$.
5. $|\phi_{N,m,k}| = 1$ and $|\phi_k| = 1$ $dv_g$-a.e.
6. $V_{N,m,k} dv_g \rightharpoonup d\mu_k$ for some probability measure $d\mu_k$.

Proof. Note that by the multiplicity bounds of [Kok1], the dimension $l(N)$ in Proposition 2.11 is bounded by a constant independent of $N$. Therefore, choosing an appropriate subsequence we may assume that the images of the maps $\phi_{N,m,k}$ lie in $\mathbb{R}^d$ for some fixed $d$. In fact, below we will be extracting subsequences from $\phi_{N,m,k}$ on a number of occasions. Slightly abusing notation for the sake of simplicity, we will denote these subsequences again by $\phi_{N,m,k}$.

Let us now prove assertions (1–6). Properties (1–3) follow from Theorem 2.7. The weak convergence in $H^1$ of a subsequence $\phi_{N,m,k}$ follows from Corollary 2.13 and the fact that any bounded sequence in $H^1$ contains a weakly convergent subsequence. Since the embedding $H^1(M) \to L^2(M)$ is compact, one can extract a subsequence that strongly converges in $L^2$. This proves property (4). The first part of property (5) is a direct consequence of Proposition 2.11. In order to prove the second assertion of (5) we argue as follows. First, we note that the measures of the sets $E_{N,k}$ defined by (2.3.3) tend to zero as $N \to \infty$. Indeed, by (2.2.4) one has that

\begin{equation}
\Lambda_k \geq \int_{E_{N,k}} W_{N,k} dv_g \geq \frac{N}{2} dv_g(E_{N,k}),
\end{equation}

i.e. $dv_g(E_{N,k}) \leq CN_1$. Therefore, by Proposition 2.11 $|\phi_{N,m,k}|$ converges to $1$ in measure, and hence one may choose a subsequence that converges almost everywhere to 1. Therefore, by dominated convergence, $|\phi_{N,m,k}|$ converges to $1$ in $L^2$, and by property (4) we get that $|\phi_k| = 1$ almost everywhere. Finally, property (6) follows from the second part of (3), since
any bounded sequence of measures contains a *-weakly convergent subsequence.

3. Analytic tools

3.1. Capacity and quasi-continuous representatives. Throughout this section let $\Omega \subset \mathbb{R}^2$ be an open set. Recall that the capacity of a set $E \subset \Omega$ is defined by

$$\text{Cap}(E, \Omega) = \inf_{U \in \mathcal{U}_E} \left\{ \int_\Omega |\nabla u|^2 \, dx \, dy \right\},$$

where $u \in \mathcal{U}_E \subset H_0^1(\Omega)$ iff $u \geq 1$ almost everywhere on an open neighbourhood of $E$. The standard mollification argument shows that it is sufficient to consider only test-functions from $C_0^\infty(\Omega)$ such that $0 \leq u \leq 1$ and $u \equiv 1$ in a neighbourhood of $E$.

If a certain property holds everywhere on $\Omega$ except for a subset $Z \subset \Omega$ such that $\text{Cap}(Z, \Omega) = 0$, then we say that it holds quasi-everywhere on $\Omega$ (or q.e. on $\Omega$). A subset $A \subset \Omega$ is quasi-open if for any $\varepsilon > 0$ there exists an open set $A_\varepsilon$ such that $\text{Cap}(A \triangle A_\varepsilon, \Omega) < \varepsilon$. A function $f: \Omega \to \mathbb{R}$ is called quasi-continuous if for any $\varepsilon$ there exists a set $E_\varepsilon$ such that $\text{Cap}(E_\varepsilon, \Omega) < \varepsilon$ and $f: \Omega \setminus E_\varepsilon \to \mathbb{R}$ is a continuous function.

The next proposition, as well as its corollaries below, is well-known. Its proof, which essentially follows [HePi, Section 3.3.4], is included to make the presentation self-contained.

**Proposition 3.1.** Let $\{u_n\} \subset C_0^\infty(\Omega)$ be a Cauchy sequence with respect to $H_0^1(\Omega)$-norm. Then there exists a subsequence $\{u_{n_k}\}$ converging pointwise outside of a set of capacity 0. Moreover, the convergence is uniform outside of a set of arbitrarily small capacity.

**Proof.** Choose a subsequence $\{u_{n_k}\}$ such that $\|u_{n_k} - u_{n_{k+1}}\|^2_{H_0^1(\Omega)} \leq 2^{-3k}$. To simplify the notations we continue to denote that subsequence by $\{u_k\}$. Set

$$E_k = \left\{ x \in \Omega \mid |u_k(x) - u_{k+1}(x)| > 2^{-k} \right\}.$$

Then one has that $2^k |u_k - u_{k+1}| \in \mathcal{U}_{E_k}$. Therefore,

$$\text{Cap}(E_k, \Omega) \leq 2^{2k} \int_\Omega |\nabla |u_k - u_{k+1}||^2 \, dx \, dy \leq 2^{-k}.$$

Set $F_m = \bigcup_{k \geq m} E_k$, then one has

$$\text{Cap}(F_m, \Omega) \leq \sum_{k=m}^{\infty} \text{Cap}(E_k, \Omega) \leq \sum_{k=m}^{\infty} 2^{-k} = 2^{1-m}.$$
If \( x \in \Omega \setminus F_m \), then for all \( k \geq m \) one has \( |u_k(x) - u_{k+1}(x)| \leq 2^{-k} \). Therefore, for any \( k, n \geq m \) one has

\[
|u_k(x) - u_n(x)| \leq \sum_{i=k}^{n-1} |u_i(x) - u_{i+1}(x)| \leq 2^{1-k},
\]

i.e. \( \{u_k\} \) converge uniformly on \( \Omega \setminus F_m \).

Set \( G = \bigcap_m^m F_m \). Then outside of \( G \) the sequence \( \{u_k\} \) converges pointwise. Moreover, for any \( n \) one has

\[
\text{Cap}(G, \Omega) \leq \text{Cap}(F_n, \Omega) \leq 2^{1-n}.
\]

Since \( n \) is arbitrary, one has \( \text{Cap}(G, \Omega) = 0 \). \( \square \)

The last assertion of Proposition 3.1 immediately implies:

**Corollary 3.2.** Any function \( u \in H^1_0(\Omega) \) has a quasi-continuous representative \( \tilde{u} \). Moreover, \( \tilde{u} \) is unique up to a set of zero capacity.

**Remark 3.3.** In the following, when we work with a function \( u \in H^1_0(\Omega) \), we always assume that \( u \) is a quasi-continuous representative.

Under this convention the capacity can be computed using the following formula,

\[
\text{Cap}(E, \Omega) = \inf_{\mathcal{V}_E} \left\{ \int_{\Omega} |\nabla u|^2 \, dx \, dy \right\},
\]

where \( \mathcal{V}_E = \{ u \in H^1_0(\Omega) | u \text{ is quasicontinuous, } u \geq 1 \text{ q.e. on } E \} \). Furthermore, the sets \( \{u > c\}, \{u < c\} \) are quasi-open.

If \( A \subset \Omega \) is quasi-open, we define \( H^1_0(A) \) to be a set of \( u \in H^1_0(\Omega) \) such that \( u = 0 \) q.e. in \( \Omega \setminus A \). This definition agrees with the classical definition of \( H^1_0(A) \) if \( A \) is open. The following proposition is a straightforward corollary of Proposition 3.1 and Corollary 3.2.

**Proposition 3.4.** Suppose that \( u_n \to u \) in \( H^1_0(B_p) \). Then there exists a subsequence \( \{u_{n_k}\} \) such that for any \( \varepsilon > 0 \) there exists a set \( E_\varepsilon \subset \Omega \) with \( \text{Cap}(E_\varepsilon, \Omega) < \varepsilon \) such that \( u_{n_k} \Rightarrow u \) in \( \Omega \setminus E_\varepsilon \).

Our next goal is to define quasi-continuous representatives for \( H^1 \)-functions. Let \( F \Subset \Omega \) be a compact subset of \( \Omega \) with the extension property, i.e. all functions in \( H^1(F) \) can be extended to \( H^1(\mathbb{R}^2) \) and, as a result to \( H^1_0(\Omega) \) as well. For example, all Euclidean balls and, in general, all Lipschitz domains possess the extension property. Let \( u \in H^1(F) \) and let \( v \in H^1_0(\Omega) \) be its extension. Then \( v \) has a quasi-continuous representative \( \tilde{v} \) and, as a result, \( \tilde{v}|_{F} \) is a quasi-continuous representative of \( u \). In the following we assume that functions from \( H^1(F) \) are quasi-continuous.

**Corollary 3.5.** Suppose that \( p \in \Omega \) and let \( B_r(p) \Subset \Omega \) be a ball of radius \( r \). Suppose that \( u_n \to u \) in \( H^1(B_r(p)) \). Then there exists a subsequence \( u_{n_k} \)
such that for any $\varepsilon > 0$ there exists a set $E_\varepsilon \subset B_\varepsilon(p)$ with $\text{Cap}(E_\varepsilon, \Omega) < \varepsilon$ such that $u_{n_k} \rightharpoonup u$ in $B_\varepsilon(p) \setminus E_\varepsilon$.

**Proof.** Apply Proposition 3.4 to the extensions of $u_n$. \hfill \Box

The following proposition is a simplified version of the isocapacitary inequality (see, for example, [Kok2]).

**Proposition 3.6.** Let $\mu \neq 0$ be a Radon measure on $\Omega$, $\mu(\Omega) < \infty$. Then for any $F \subset \Omega$ one has,

\begin{equation}
\mu(F) \leq \frac{1}{\lambda_1 D(\Omega, \mu)} \text{Cap}(F, \Omega).
\end{equation}

**Proof.** Without loss of generality $\text{Cap}(F, \Omega) < \infty$. For a fixed $\varepsilon > 0$ let $u_\varepsilon \in H^0_1(\Omega)$ be such that $u_\varepsilon|_F \geq 1$, $u_\varepsilon \geq 0$ and

$$
\int \limits_\Omega |\nabla u_\varepsilon|^2 \, dx \, dy \leq \text{Cap}(F, \Omega) + \varepsilon.
$$

Since $\mu \neq 0$, we have $\lambda_1^D(\Omega, \mu) < \infty$. Using $u_\varepsilon$ as a test-function for the Rayleigh quotient, one obtains,

$$
\lambda_1^D(\Omega, \mu) \mu(F) \leq \lambda_1^D(\Omega, \mu) \int \limits_\Omega u_\varepsilon^2 \, d\mu \leq \int \limits_\Omega |\nabla u_\varepsilon|^2 \, dx \, dy \leq \text{Cap}(F, \Omega) + \varepsilon.
$$

Since $\varepsilon$ is arbitrary, the proof is complete. \hfill \Box

**Lemma 3.7.** Let $[a, b] \subset \mathbb{R}$ be a bounded interval. Then any $f \in H^1[a, b]$ is absolutely continuous and one has

$$
||f||^2_{C_0} \leq \max(b - a, 2)||f||_{L^2}||f||_{H^1}.
$$

**Proof.** Absolute continuity follows from the Rellich compactness theorem. For two point $x, y \in [a, b]$ we write

$$
f^2(x) - f^2(y) = \frac{1}{2} \int \limits_x^y f(t)f'(t) \, dt \leq \frac{1}{2} ||f||_{L^2}||f'||_{L^2}.
$$

Integrating in $y$ we obtain for all $x$

$$
f^2(x) \leq \frac{b - a}{2} ||f||_{L^2}||f'||_{L^2} + ||f||^2_{L^2} \leq \max(b - a, 2)||f||_{L^2}||f||_{H^1},
$$

where in the last step we used inequality $\sqrt{c} + \sqrt{d} \leq 2\sqrt{(c + d)}$ for $c, d \geq 0$. \hfill \Box

The following proposition is essentially well-known and is a version of the “absolute continuity on lines” property of functions in $H^1$ (see, for instance, [HKST, Chapter 6]). However, our formulation differs from the standard one due to the fact that we always take a particular representative of an $H^1$ function, see Remark 3.3.
Proposition 3.8. Let \( R = [a, b] \times [c, d] \subseteq \Omega \) be a rectangle. For any quasicontinuous \( u \in H^1(R) \) let \( X \subset [a, b] \) be a set consisting of points \( x \) such that \( u^x(y) := u(x, y) \) is absolutely continuous as a function of \( y \) and \((u^x)'(y) \in L^2[c, d]\). Then \( X \) is a set of full measure.

Proof. Let \( v \in H^1_0(\Omega) \) be an extension of \( u \). Let \( \{v_n\} \) be a sequence of functions in \( C_0^\infty(\Omega) \) that converge to \( v \) in \( H^1_0(\Omega) \). By Proposition 3.4 we can assume that \( v_n \) converge to \( v \) outside of a set of capacity 0. Let \( u_n = v_n|_R \), then \( u_n \in C^\infty(R) \) and \( u_n \) converge to \( u \) pointwise in \( R \) outside of a set of capacity 0.

By Fubini’s theorem one has that the functions

\[
\int_c^d (u_n(x, y) - u(x, y))^2 + \left( \frac{d}{dy} (u_n(x, y) - u(x, y)) \right)^2 \, dy
\]

tend to 0 in \( L^1[a, b] \) and, therefore, up to a choice of a subsequence, pointwise to 0 for almost all \( x \in [a, b] \). As a result, for almost all \( x \in [a, b] \) the sequence \( \{u_n\} \) converges in \( H^1[c, d] \) and, therefore, uniformly as well. The problem is that, they may converge to a different representative of an \( H^1 \) function.

Let \( X' \) be a set of \( x \in [a, b] \) for which there exists \( y \) such that \( u_n(x, y) \) does not converge to \( u(x, y) \). We claim that \( X' \) has measure 0. First, let us see why it completes the proof of the proposition. Indeed, for almost all \( x \in [a, b] \) the sequence \( \{u_n\} \) converge outside of \( X' \) it converges to \( u^x \) both in \( C[c, d] \) and in \( H^1[c, d] \). Therefore, for such \( x \) the function \( u^x \) is absolutely continuous and \((u^x)' \in L^2[c, d]\).

To show that \( X' \) has measure 0 we take \( \phi_\varepsilon \in C_0^\infty(\Omega) \) such that \( \phi_\varepsilon \geq 1 \) on the set where \( u_n(x, y) \) does not converge to \( u(x, y) \) and \( |\phi_\varepsilon|_{H^1(R)} < \varepsilon \). We let \( c(x) = |\phi_\varepsilon|^2_{C[c, d]} \), \( h(x) = |\phi_\varepsilon|^2_{H^1[c, d]} \). Then by Lemma 3.7 one has

\[
(3.1.2) \quad c(x)^2 \leq Ch(x)^2.
\]

Note that \( c(x) \geq 1 \) on \( X' \). Therefore, integrating from \( c \) to \( d \) we obtain the following,

\[
|X'| \leq C|\phi_\varepsilon|_{H^1(R)}^2 < C\varepsilon^2.
\]

Since \( \varepsilon \) is arbitrary, we conclude that \( X' \) has measure 0. \( \square \)

3.2. Three auxiliary lemmas. Recall that if \( V \in L^\infty(\Omega) \), the first Dirichlet eigenvalue of \( \Delta - V \) on \( A \) is defined as

\[
\inf_{u \in H^1_0(A)} \frac{\int_A |
abla u|^2 - Vu^2 \, dxdy}{\int_A u^2 \, dxdy}.
\]

Lemma 3.9. Let \( A \subset \Omega \) be quasi-open and let \( V \in L^\infty(\Omega) \). Suppose that \( \phi \in H^1(\Omega) \) is a weak solution to \( \Delta \phi - V \phi = 0 \) on \( A \). Assume that the first eigenvalue of \( \Delta - V \) in \( H^1_0(A) \) is positive. Then for any \( \psi \in H^1(\Omega) \) such
Lemma 3.11. Let \( \{\rho\} \cup \Omega \) be quasi-open and \( \{\rho\} \cup \Omega \) is quasi-continuous. Then
\[
\int_{\Omega} |\nabla \psi|^2 - V\psi^2 \, dx \, dy \geq \int_{\Omega} |\nabla \phi|^2 - V\phi^2 \, dx \, dy
\]

Proof. From the eigenvalue condition we have that
\[
(3.2.1) \quad \int_{\Omega} |\nabla (\phi - \psi)|^2 - V(\phi - \psi)^2 \, dx \, dy \geq 0.
\]
Moreover, pairing up the equation for \( \phi \) with \( \psi - \phi \), we obtain
\[
\int_{\Omega} \nabla \phi \cdot \nabla (\psi - \phi) - V\phi(\psi - \phi) \, dx \, dy = 0,
\]
or, equivalently,
\[
(3.2.2) \quad \int_{\Omega} \nabla \phi \cdot \nabla \psi - V\phi \psi \, dx \, dy = \int_{\Omega} |\nabla \phi|^2 - V\phi^2 \, dx \, dy,
\]
Summing up (3.2.1) and two copies of (3.2.2) yields
\[
\int_{\Omega} |\nabla \phi|^2 + |\nabla \psi|^2 - V(\phi^2 + \psi^2) \, dx \, dy \geq 2 \int_{\Omega} (|\nabla \phi|^2 - V\phi^2) \, dx \, dy.
\]
Rearranging the terms completes the proof. \( \square \)

In what follows we use the following notations: \( B_r(p) \) denotes the ball of radius \( r \) with center at \( p \); \( S_r(p) = \partial B_r(p) \) is a circle of radius \( r \) with center at \( p \) and \( A_{r,R}(p) = B_R(p) \setminus B_r(p) \) is an annulus around \( p \).

Lemma 3.10. Let \( B_r(p) \subset B_R(p) \subset \Omega \) be two balls. Let \( u, v \in H^1(B_R(p)) \) be such that \( u|_{S_R(p)} > v|_{S_R(p)} \) and \( u|_{S_r(p)} < v|_{S_r(p)} \). Then there exists a quasi-open set \( A \) satisfying \( B_r(p) \subset A \subset B_R(p) \) and \( (u - v)|_A \in H^1_0(A) \). Moreover, the extension of \( (v - u)|_A \) by zero to a function in \( H^1_0(\Omega) \) is quasi-continuous.

Proof. Let \( \hat{u}, \hat{v} \in H^1_0(\Omega) \) be extensions of \( u, v \) respectively. Set \( \hat{A} = \{v - u > 0\} \) be a quasi-open subset of \( \Omega \). Moreover, \( \hat{w} = (v - u)_+ \) is quasi-continuous such that \( \hat{w} = 0 \) on \( S_R(p) \) and \( \hat{w} = v - u \) on \( S_r(p) \). Therefore, the function
\[
w(x) = \begin{cases} 
0 & x \in \Omega \setminus B_r(p) \\
\hat{w}(x) & x \in B_R(p) \setminus B_r(p) \\
v(x) - u(x) & x \in B_r(p)
\end{cases}
\]
is quasi-continuous. Then \( A = \{w > 0\} \cup B_r(p) = (\hat{A} \cap B_R(p)) \cup B_r(p) \) is quasi-open and \( w \) is an extension of \( (v - u)|_A \) by zero. \( \square \)

Lemma 3.11. Let \( U = A_{r,R}(p) \subset \Omega \) be an annulus around a point \( p \in \Omega \). Let \( \{u_n\} \subset H^1(U) \) and \( u \in H^1(U) \) be such that \( \{u_n\} \) is equibounded in \( H^1(U) \) and \( u_n \to u \) in \( L^2(U) \). Then up to a choice of a subsequence the set \( \{\rho| u_n|_{S_{\rho}} \Rightarrow u|_{S_{\rho}} \} \) has full measure in \( (r, R) \).
Proof. Without loss of generality, assume \( u = 0 \). Applying Proposition 3.8 in polar coordinates we see that the set \( A \) of \( \rho \) such that \( u|_{S_{\rho}} \) is absolutely continuous on \( S_{\rho} \) and its derivative is in \( L^2(S_{\rho}) \) has full measure. Then \( A = \bigcap_i A_i \) has full measure. The remainder of the proof is very similar to the proof of Proposition 3.8.

For \( \rho \in (r, R) \) define \( h_i(\rho) = ||u_i||_{H^1(S_{\rho})} \), \( l_i(\rho) = ||u_i||_{L^2(S_{\rho})} \) and \( c_i(\rho) = ||u_i||_{C^0(S_{\rho})} \). Application of Lemma 3.7 yields that for all \( \rho \in A \) one has \( c_i(\rho)^2 \leq Cl_i(\rho)h_i(\rho) \).

By Fubini’s theorem \( l_i \in L^2(r, R) \) and \( h_i \in L^2(r, R) \). Since \( ||u_i||_{H^1(A_r, R)} \leq C_0 \), one has \( ||h_i||_{L^2(r, R)} \leq C_0 \).

Integrating over \((r, R)\) yields

\[ ||c_i||^2_{L^2(r, R)} \leq CC_0 ||l_i||_{L^2(r, R)} \to 0. \]

Thus, \( c_i^2 \to 0 \) in \( L^2(r, R) \). Therefore, there exists a subsequence \( i_k \) such that \( c_{i_k}(\rho) \to 0 \) for almost all \( \rho \in (r, R) \). \( \square \)

**Corollary 3.12.** Let \( B_{R_0}(p) \subseteq \Omega \). Suppose that \( \{u_n\} \) is a bounded sequence in \( H^1(B_{R_0}(p)) \) such that \( u_n \to u \) in \( L^2(B_{R_0}(p)) \), \( u \in H^1(B_{R_0}(p)) \). Then for any \( r_0 < R_0 \) up to a choice of a subsequence there exist \( r_0 < r < R < R_0 \) and a sequence \( \{v_n\} \subset H^1(B_R) \) such that

1) \( ||v_n - u||_{\infty} \to 0 \)
2) \( v_n > u_n \) on \( S_r(p) \)
3) \( v_n < u_n \) on \( S_R(p) \)
4) \( ||v_n - u||_{H^1(B_R)} \to 0 \)
5) \( ||\nabla v_n||^2_{L^2(B_R)} - ||\nabla u||^2_{L^2(B_R)} \to 0 \)

Proof. We apply Lemma 3.11 to \( A_{R_0,r} \). We get the subsequence such that the set \( \{\rho \mid u_n|_{S_{\rho}} \equiv u|_{S_{\rho}}\} \) is dense in \((r_0, R_0)\). Choose any \( r < R \) from this set. Define a sequence \( N(k) \) such that for \( n \geq N(k) \) one has \( |u_n - u|_{S_r \cup S_R} < 2^{-k} \). For \( n \in [N(k), N(k + 1)] \) we set \( v_n \) to be \( u + h_k \) where \( h_k \) is a radial function with \( h_k \equiv 2^{-k} \) on \( B_r \) and linear on \( A_{R,r} \) with \( h_k(R) = -h_k(R) = 2^{-k} \). The properties 1)-3) follow immediately. Moreover,

\[ \int_{B_R} ||\nabla h_k||^2 = 2\pi \int_r^R \left( \frac{2^{1-k}}{R-r} \right)^2 \rho \, d\rho = \pi 2^{2-2k} \frac{R+r}{R-r}, \]

and 4) follows.

In the following computation we use \( || \cdot || \) to denote \( || \cdot ||_{L^2(B_R)} \). One has,

\[ ||\nabla v_n||^2 - ||\nabla u||^2 \leq ||\nabla v_n - \nabla u|| (||\nabla u|| + ||\nabla v_n||) \]

and 5) follows from 4) and equiboundedness of \( \{v_n\} \) in \( H^1(B_R) \). \( \square \)
3.3. Some properties of Radon measures. Given a Radon measure $\nu$ on $\Omega$, one can define the corresponding Laplace eigenvalues with Dirichlet boundary conditions variationally by the following formula (see [Kok2]):

$$\lambda^D_k(M, \nu) = \inf_{E_k} \sup_{u \in E_k} \int \frac{|\nabla u|^2 \, dx \, dy}{\int \Omega u^2 \, d\nu},$$

where the supremum is taken over $E_k \subset C^\infty_0(\Omega)$ which form $k$-dimensional subspaces in $L^2(\nu)$. Furthermore, we assume the convention that the infimum over an empty set is equal to $+\infty$ and, as a result, all eigenvalues corresponding to the zero measure are equal to $+\infty$.

The following two auxiliary results on Radon measures will be used in Section 4.

**Proposition 3.13.** Suppose that $\mu$ is a finite Radon measure on $U \subset \Omega$ such that $\lambda^D_1(U, \mu) \geq C > 0$. Then for any quasi-continuous $v \in H^1_0(U)$ such that $|v| \leq 1$ one has

$$\int_U |v| \, d\mu \leq \left( \mu(U) + \frac{1}{C} \right) \left( \int_U |\nabla v|^2 \, dv_g \right)^{1/3}.$$

**Proof.** Set $\gamma^3 = \int_U |\nabla v|^2 \, dv_g$. We decompose $U = U_1 \cup U_2$, where $U_1 = \{0 \leq |v| < \gamma\}$ and $U_2 = \{\gamma \leq |v|\}$. Using $|v|/\gamma$ as a test-function we obtain

$$\text{Cap}(U_2, U) \leq \gamma.$$

Then the isocapacitory inequality (3.1.1) implies

$$\mu(U_2) \leq \frac{\gamma}{C}.$$

Finally, one obtains

$$\int_U |v| \, d\mu \leq \int_{U_1} |v| \, d\mu + \int_{U_2} |v| \, d\mu \leq \gamma \mu(U_1) + \gamma/C$$

$\Box$

Finally, we recall the following proposition related to $*$-weak convergence of Radon measures.

**Proposition 3.14.** Let $V \Subset U$. Assume that $u_n$ converge weakly in $L^2(U)$ to $u$ and $u_n^2 \, dv_g$ converge $*$-weakly to $dv$ as measures on $V$. Then for any $W \subset V$ one has

$$\nu(W) \geq \int_W u^2 \, dv_g.$$

Moreover, equality holds for all $W \subset V$ iff $u_n$ converge to $u$ in $L^2(V)$.

**Proof.** Let us first recall that $*$-convergence implies that

$$\nu(W) \geq \limsup_{n} \int_W u_n^2 \, dv_g \geq \liminf_{n} \int_W u_n^2 \, dv_g \geq \nu(W)$$

(3.3.2)
for all $W \subset V$.

At the same time, for $u_n$ converge to $u$ weakly in $L^2(W)$. Therefore, by lower semicontinuity of the norm with respect to weak topology, one has

$$\liminf \int_W u_n^2 \, dv_g \geq \int_W u^2 \, dv_g.$$ Combining it with the inequality \[3.3.2\] we have a chain of inequalities

$$\nu(W) \geq \limsup \int_W u_n^2 \, dv_g \geq \limsup \int_W u_n^2 \, dv_g \geq \int_W u^2 \, dv_g,$$
which yields the first assertion.

Assume that we have an equality for all $W$. Therefore, in the previous chain all inequalities are actually equalities. In particular, one has that

$$\lim \int_V u_n^2 \, dv_g = \int_V u^2 \, dv_g,$$
which yields $u_n \to u$ in $L^2(V)$.

Assume that $u_n \to u$ in $L^2(V)$, then it is easy to see that $d\nu = u^2 \, dv_g$. Indeed, for any continuous function $\phi$ on $V$ one has

$$\left| \int_V \phi(u_n^2 - u^2) \, dv_g \right| \leq \|\phi\|_{\infty} \left| \int_V u_n^2 \, dv_g - \int_V u^2 \, dv_g \right| \to 0.$$

\[ \square \]

3.4. **Note on cut-off functions.** Given $R > r$, a straightforward computation shows that

$$\text{Cap}(B_r(p), B_R(p)) \leq \frac{2\pi}{\ln \frac{R}{r}}.$$ Indeed, the following function provides a suitable test-function

\begin{equation}
(3.4.1) \quad f_{r,R}(\rho) = \begin{cases} 
\frac{\ln \frac{R}{\rho}}{\ln \frac{R}{r}} & \text{on } A_{r,R}(p) \\
\frac{\ln \frac{R}{\rho}}{\ln \frac{R}{r}} & \text{on } B_r(p),
\end{cases}
\end{equation}
where $\rho$ is the radial coordinate.

In the following, when we consider a cut-off function, we always mean the function defined by \[3.4.1\] for a suitable choice of radii $r, R$.

4. **Regularity properties of the limiting measure**

The goal of this section is to prove the following theorem.

**Theorem 4.1.** Let $d\mu_k$ be the limiting measure as in property (6) of Theorem 2.14. Then there exist at most $k$ points $p_1, \ldots, p_l, l \leq k$ and a harmonic map $\phi_k: U \to S^{d-1}$ such that

$$d\mu_k = \frac{|
abla \phi_k|^2}{A} \, dv_g + \sum_{i=1}^l w_i \delta_{p_i},$$
where $w_i \geq 0$. 

Remark 4.2. The zeros of the gradient of a harmonic function are isolated, and, therefore, the points where $|\nabla \phi_k| = 0$ correspond to the conical singularities of the limiting metric (see [Kok2 Section 5.3]).

4.1. Measure properties of $\mu_k$. We first define the eigenvalues of a Radon measure on a surface similarly to (3.3.1). Let $M$ be a surface and let $C$ be a fixed conformal class on $M$ with a smooth background metric $g \in C$. Given a Radon measure $\nu$ on $M$, one can define the corresponding Laplace eigenvalues variationally by the following formula (see [Kok2]):

\[ \lambda_k(M, \nu) = \inf_{E_k} \sup_{u \in E_k} \frac{\int_M |\nabla u|^2 \, dv_g}{\int_M u^2 \, d\nu}, \]

where the supremum is taken over $E_k \subset C^\infty(M)$ which form $(k+1)$-dimensional subspaces in $L^2(d\nu)$. Similarly, given a domain $U \subset M$, we define the Dirichlet eigenvalues $\lambda_{Dk}(U, \nu)$ by replacing $M$ by $U$ in the Rayleigh quotient and $C^\infty(M)$ by $C^\infty_0(U)$ in the definition of $E_k$ and requiring $E_k$ to be $k$-dimensional instead $(k+1)$-dimensional. As before, all eigenvalues of the zero measure are assumed to be equal to $+\infty$.

Lemma 4.3. Let $\nu$ be a Radon measure. Let $U_1, \ldots, U_{k+1} \subset M$ be a disjoint collection of open sets. Then for at least one $i$ one has $\lambda_{D1}(U_i, \nu) \geq \lambda_k(M, \nu)$.

Proof. If $\nu|_{U_i} = 0$ for some $i$, then it follows from (4.1.1) that $\lambda_{Dk}(U_i, \nu) = +\infty$, and the statement of the lemma is trivial. Assume that $\nu|_{U_i} \neq 0$ for all $i = 1, \ldots, k+1$. This condition implies that $\lambda_{Dk}(U_i, \nu) < +\infty$. Arguing by contradiction, assume that for all $i$ one has $\lambda_{Dk}(U_i, \nu) < \lambda_k(M, \nu)$. Take the first Dirichlet eigenfunctions $f_i$ of $U_i$; continue them to the whole $M$ by zero, and apply the variational principle for $\lambda_{Dk}(M, \nu)$ to the subspace of test-functions span\{$f_1, \ldots, f_{k+1}$\}. We get a contradiction. \hfill $\square$

Let $\nu_V$ be a Radon measure such that $d\nu_V = V \, dv_g$ for some $V \in L^\infty(M)$. As before, we will write $\lambda_k(V) := \lambda_k(M, V) = \lambda_k(M, \nu_V)$ and $\lambda_{Dk}(\Omega, V) := \lambda_{Dk}(\Omega, \nu)$.

Definition 4.4. We say that a domain $\Omega \subset M$ satisfies $\sigma_k$-property for some $N \in \mathbb{N}$, if

$\lambda_{Dk}(\Omega, V_N) \geq \Lambda_k^N$

or, equivalently, if the first eigenvalue of the Schrödinger operator $\Delta - \Lambda_k^N V_N$ on $H^1_0(\Omega)$ is non-negative.

In particular, if $V_N|_\Omega = 0$, then $\Omega$ satisfies $\sigma_k$-property for any $N$ since in this case $\lambda_{Dk}(\Omega, V_N) = +\infty$.

Definition 4.5. We say that the point $p$ is good if there exists an open neighbourhood $\Omega_p$ that satisfies $\sigma_k$-property for a subsequence $N_m \to \infty$. Otherwise, we say that the point $p$ is bad.
Note that for any subdomain of \( U_p \subset \Omega_p \) the \( \sigma_k \)-property is satisfied for the same subsequence \( N_m \). Indeed, this immediately follows from the domain monotonicity for Dirichlet eigenvalues.

Let \( G \) denote the set of all good points. Clearly, \( G \) is an open set, since if \( p \in G \), then \( \Omega_p \subset G \).

**Proposition 4.6.** There exist \( k \) points \( p_1, \ldots, p_k \) such that \( G \supset M \setminus \{p_1, \ldots, p_k\} \), i.e. all but at most \( k \) points are good.

**Proof.** Assume the contrary, i.e. there exists \( k + 1 \) bad points \( p_1, \ldots, p_{k+1} \). Pick disjoint open neighbourhoods \( U_i \ni p_i \). By Lemma 1.3 applied to the measure \( \nu_i \), for any \( N \in \mathbb{N} \) there exists \( i(N) \) such that \( \lambda_k(U_i, V_N) \geq \Lambda_k^N \).

Therefore, there exists a subsequence \( N_m \) such that \( i(N_m) = i_0 \) is constant, i.e. the point \( p_{i_0} \) is good. We arrive at a contradiction. \( \square \)

For the remainder of this section for each point \( p \) we fix a small open neighbourhood \( \Omega_p \) such that \( g \) is conformally flat on \( \Omega_p \). This way we can use the capacity estimates of Section 3 with \( \Omega = \Omega_p \) whenever we are working in the neighbourhood of \( p \).

**4.2. Strong convergence in \( H^1 \) in a neighbourhood of a good point.**

**Proposition 4.7.** Given a good point \( p \), there exists a neighborhood \( X \ni p \) and a sequence \( N_m \to \infty \) such that \( \phi_{N_m,k} \to \phi_k \) in \( H^1(X) \).

**Remark 4.8.** This proposition could be viewed as an \( \varepsilon \)-regularity-type theorem (see [CM]) in the following sense. We claim that if \( \frac{1}{\lambda_1^D(\Omega)} \) is small, then weak \( H^1 \) convergence of \( \phi_{N_m,k} \) implies strong convergence in \( H^1(X) \) for some \( X \subset \Omega \).

**Proof.** Assume, by contradiction, that there is no such neighborhood. Let \( U \) be a neighbourhood of \( p \) such that \( U \) satisfies \( \sigma_k \)-property for all large enough \( N \). Let \( p \in Y \subset U \). Choose a subsequence \( N_m \to \infty \) such that \( |\nabla \phi_{N_m,k}|^2 \, dv_g \) converges \(*\)-weakly to \( dv \) as measures on \( Y \). Indeed, such a subsequence exists because \( \phi_{N_m,k} \) is weakly convergent in \( H^1 \) by assertion (4) in Theorem 2.14 and hence the measures \( |\nabla \phi_{N_m,k}|^2 \, dv_g \) are bounded and contain a \(*\)-weakly convergent subsequence. For any \( X \subset Y \) the restrictions of these measures converge as measures on \( X \). We claim that there exists a point \( q \in \text{supp}(dv - |\nabla \phi_k|^2 \, dv_g) \cap Y \). Indeed, by Proposition 3.14 applied to \( |\nabla \phi_{N_m,k}| \) and \( V \) one has \( \text{supp}(dv - |\nabla \phi_k|^2 \, dv_g) \neq \emptyset \). If the support is concentrated on \( \partial Y \) then for any \( p \in X \subset Y \) one has \( dv|_X = |\nabla \phi_k|^2 \, dv_g|_X \).

Then by Proposition 3.14 \( |\nabla \phi_{N_m,k}| \to |\nabla \phi_k| \) in \( L^2(X) \) which implies that for any \( i \) one has \( |\nabla u^i_{N_m,k}|^2 \to |\nabla u^i_k|^2 \) in \( L^1(W) \). Since \( \phi^i_k \to \phi_k \) in \( L^2(M) \), this implies that components converge in \( H^1(X) \) in contradiction with our initial assumption. Let

\[
\text{(4.2.1) } \quad q \in \text{supp}(dv - |\nabla \phi_k|^2 \, dv_g) \cap Y,
\]
and let \( r < R \) be such that \( B_R(q) \subset Y \). In the argument below we will be consequently refining the disks \( B_r(q) \subset B_R(q) \) and the sequence \( \{N_m\} \) by picking new \( r_0, R_0 \) satisfying \( r < r_0 < R_0 < R \) in a way that they satisfy more and more conditions. Each condition will be preserved under such refinement. After each refinement we will omit the index 0 from our notations and keep the notation \( N_m \) for the subsequence. This way eventually we obtain the disks \( B_r(q) \subset B_R(q) \) and a subsequence \( N_m \to \infty \) satisfying conditions (C1) – (C4) below.

In view of (4.2.1), there exists \( \epsilon > 0 \) such that

\[
(C1) \quad \nu(B_r(q)) - \int_{B_r} |\nabla \phi_k|^2 \, dv_g > 2\epsilon.
\]

The condition (C2) is as follows,

\[
(C2) \quad \int_{A_{r,R}(q)} |\nabla \phi_{N_m,k}|^2 \, dv_g < \frac{\epsilon}{3}
\]

for all \( N_m \). In order to satisfy this condition we divide the initial annulus \( A_{r,R} \) into \( K \) sub-annuli. Since the sequence \( \phi_{N_m,k} \) is bounded in \( H^1(M) \), one can take \( K \) so large that for each \( N_m \) at least one of subannuli satisfies (C2). Since there are finitely many such subannuli one can choose a subsequence such that condition (C2) is satisfied for all members of the subsequence.

Properties (C1) and (C2) imply that for large enough \( N_m \),

\[
(C3) \quad \int_{B_r} |\nabla \phi_{N_m,k}|^2 \, dv_g + \int_{B_r} |\nabla \phi_k|^2 \, dv_g + \epsilon
\]

Indeed, condition (C1) and the last inequality in formula (3.3.2) yield

\[
\liminf \int_{B_r} |\nabla \phi_{N_m,k}|^2 \, dv_g - \int_{B_r} |\nabla \phi_k|^2 \, dv_g \geq \nu(B_r) - \int_{B_r} |\nabla \phi_k|^2 \, dv_g > 2\epsilon.
\]

Therefore, for large enough \( N_m \) one has

\[
\int_{B_r} |\nabla \phi_{N_m,k}|^2 \, dv_g \geq \int_{B_r} |\nabla \phi_k|^2 \, dv_g + 2\epsilon.
\]

At the same time, property (C2) together with the fact that \( \phi_{N_m,k} \) converge weakly in \( H^1 \) to \( \phi_k \) (and thus \( \liminf_{N_m \to \infty} \|\phi_{N_m,k}\|_{H^1} \geq \|\phi_k\|_{H^1} \)) implies that

\[
\int_{A_{r,R}} |\nabla \phi_k|^2 \, dv_g < \frac{\epsilon}{3}.
\]

Summing this up with the previous inequality yields (C3).

Finally, we would like to ensure that the annulus \( A_{r,R} \) satisfies

\[
(C4) \quad \int_{A_{r,R}} V_N \, dv_g \leq \frac{\epsilon}{9\Lambda_k d}.
\]

It is achieved in the same way as for condition (C2).
At this point we apply Corollary 3.12 to each component $u_{N,m,k}^i$ and balls $B_r \subset B_R$ to get a sequence $v_{N,m,k}^i$. We then apply Lemma 3.10 to $v_{N,m,k}^i$ and $u_{N,m,k}^i$ to get a quasi-open set $A_{N,m}^i$.

Since $B_R$ satisfies $\sigma_k$-property for all $N_m$, we can apply Lemma 3.9 with $\phi = u_{N,m,k}^i$, $\psi = v_{N,m,k}^i$, $V = V_{N,m,k}$ and $A = A_{N,m}^i$ to conclude

$$\int_{A_{N,m}^i} (|\nabla v_{N,m,k}^i|^2 - \Lambda_{N,m}^i (v_{N,m,k}^i)^2 V_{N,m,k}) \, dv_g \geq \int_{A_{N,m}^i} (|\nabla u_{N,m,k}^i|^2 - \Lambda_{N,m}^i (u_{N,m,k}^i)^2 V_{N,m,k}) \, dv_g.$$  

Rearranging yields

(4.2.2)  
$$\int_{A_{N,m}^i} |\nabla v_{N,m,k}^i|^2 \, dv_g + \Lambda_{N,m}^i \int_{A_{N,m}^i} (u_{N,m,k}^i)^2 - (v_{N,m,k}^i)^2 V_{N,m,k} \, dv_g \geq \int_{A_{N,m}^i} |\nabla u_{N,m,k}^i|^2 \, dv_g.$$  

Analyzing the term in the middle, we note that the integrand is bounded in absolute value by 3, and since $B_r \subset A_{N,m}^i \subset B_R$, condition (C4) implies

$$|\Lambda_{N,m}^i \int_{B_R \setminus \Omega_{N,m}^i} ((u_{N,m,k}^i)^2 - (v_{N,m,k}^i)^2) V_{N,m,k} \, dv_g| \leq \frac{\varepsilon}{3d}.$$  

Therefore, in inequality (4.2.2) one can replace the domain of integration in the l.h.s by $B_R$ and in the r.h.s by $B_r$, with a loss of at most $\frac{\varepsilon}{3d}$ to obtain

$$\int_{B_R} |\nabla v_{N,m,k}^i|^2 \, dv_g + \Lambda_{N,m}^i \int_{B_R} (u_{N,m,k}^i)^2 - (v_{N,m,k}^i)^2 V_{N,m,k} \, dv_g + \frac{\varepsilon}{3d} \geq \int_{B_r} |\nabla u_{N,m,k}^i|^2 \, dv_g.$$  

Recall that $v_{N,m,k}^i$ were constructed using Corollary 3.12. By properties 1) and 5) for large enough $N_m$ one can replace $v_{N,m,k}^i$ by $u_k^i$ in the left hand side of the previous inequality again with a loss of at most $\frac{\varepsilon}{3d}$ to obtain

$$\int_{B_R} |\nabla u_k^i|^2 \, dv_g + \Lambda_{N,m}^i \int_{B_R} (u_k^i)^2 - (u_k^i)^2 V_{N,m,k} \, dv_g + \frac{2\varepsilon}{3d} \geq \int_{B_r} |\nabla u_{N,m,k}^i|^2 \, dv_g.$$  

Finally, we sum this inequality over all $i$ and use that $|\phi_{N,m,k}| \leq |\phi_k| = 1 \, dv_g$-a.e., which implies that the middle term on the left-hand side is nonpositive. Therefore, we obtain

$$\int_{B_R} |\nabla \phi_k|^2 \, dv_g + \frac{2\varepsilon}{3} \geq \int_{B_r} |\nabla \phi_{N,m,k}|^2 \, dv_g.$$  

Combining it with property (C3) we arrive at a contradiction. \qed
Corollary 4.9. Let \( p \in M \) be a good point. Then there exists a subsequence \( N_m \to \infty \) such that for any \( \varepsilon > 0 \) there exists a set \( E_\varepsilon \subset B_r(p) \subset \Omega \) with \( \text{Cap}(E_\varepsilon, \Omega) < \varepsilon \) such that \( \phi_{N_m,k} \rightharpoonup \phi_k \) in \( B_r(p) \setminus E_\varepsilon \).

Proof. The result follows immediately from Proposition 4.7 and Corollary 3.5.

Recall that \( G \) denotes the open set of all good points on \( M \).

Proposition 4.10. Let \( \psi \in C^\infty_0(G) \). Then for any \( i = 1, \ldots, d \), one has

\[
(4.2.3) \quad \int_G \nabla \psi \cdot \nabla u^i_k \, dv_g = \Lambda_k \int_G \psi u^i_k \, d\mu_k.
\]

Remark 4.11. Proposition 4.10 means that the functions \( u^i \) are weak solutions in \( G \) of the equation

\[
\Delta_g u^i_k \, dv_g = \Lambda_k u^i_k \, d\mu_k.
\]

Proof. Applying partition of unity, it is enough to prove the proposition for \( \psi \) with support in a small neighbourhood of a good point. In particular, for any point \( p \in G \), let \( E_\varepsilon \subset B_r(p) \) be a pair of neighbourhoods such that Proposition 4.7 holds. We set \( X = E_\varepsilon \) and \( Y = B_r(p) \). Without loss of generality, \( \sigma_k \)-property holds on \( Y \) for all large \( N \). Fix \( \varepsilon > 0 \) and let \( \{N_m\} \) and \( E_\varepsilon \subset W \) denote the corresponding subsequence and the subset. Assume \( \supp \psi \subset X \).

Let \( \beta_\varepsilon \in C^\infty_0(\Omega) \) be a smooth function such that \( 0 \leq \beta_\varepsilon \leq 1 \), \( \beta_\varepsilon = 1 \) on \( X \) and

\[
(4.2.4) \quad \int_\Omega |\nabla \beta_\varepsilon|^2 \, dv_g = \varepsilon;
\]

the latter is possible by Corollary 4.9. Recall that \( \Delta \phi_{N_m,k} = \Lambda_k^{N_m} V_{N_m,k} \phi_{N_m,k} \). Pairing it with \( \psi(1 - \beta_\varepsilon) \) we obtain

\[
\int_X \nabla u^i_{N_m,k} \cdot \nabla (\psi(1 - \beta_\varepsilon)) \, dv_g = \Lambda_k^{N_m} \int_X \psi(1 - \beta_\varepsilon) u^i_{N_m,k} V_{N_m,k} \, dv_g.
\]

We pass to the limit \( N_m \to \infty \). The limit of the l.h.s is easy, since \( \phi_{N_m,k} \rightharpoonup \phi_k \) in \( H^1(M) \). For the r.h.s. we write

\[
\left| \int_X \psi(1 - \beta_\varepsilon) u^i_{N_m,k} V_{N_m,k} \, dv_g - \Lambda_k \int_X \psi(1 - \beta_\varepsilon) u^i_k \, d\mu_k \right| \leq
\]

\[
\left| \int_X \psi(1 - \beta_\varepsilon)(\Lambda_k^{N_m} u^i_{N_m,k} - \Lambda_k u^i_k) V_{N_m,k} \, dv_g \right| + \left| \int_X \psi(1 - \beta_\varepsilon) \Lambda_k u^i_k (V_{N_m,k} \, dv_g - d\mu_k) \right|.
\]

The first summand tends to zero, because on \( \supp(\psi(1 - \beta_\varepsilon)) \) one has \( \Lambda_k^{N_m} u^i_{N_m,k} \rightharpoonup \Lambda_k u^i_k \) by Proposition 4.7. The second summand tends to zero by the definition of the *-weak convergence of measures (since \( u^i \) are continuous on \( \supp(\psi(1 - \beta_\varepsilon)) \)). Thus, we obtain

\[
(4.2.5) \quad \int_X \nabla u^i \cdot \nabla (\psi(1 - \beta_\varepsilon)) \, dv_g = \Lambda_k \int_X u^i \psi(1 - \beta_\varepsilon) \, d\mu_k.
\]
We claim that passing to the limit as $\varepsilon \to 0$ in (4.2.5) yields (4.2.3). We prove this in two steps. First, note that

\begin{equation}
\int_X \nabla u_k \cdot \nabla (\beta \varepsilon \psi) \, dv_g \to 0.
\end{equation}

Indeed,

\begin{equation}
\left| \int_X \nabla u_k \cdot \nabla (\beta \varepsilon \psi) \, dv_g \right| \leq ||\nabla u_k||_{L^2(X)} (\sup |\psi||\nabla \beta\varepsilon||_{L^2(X)} + \sup |\nabla \psi||\beta \varepsilon||_{L^2(X)}),
\end{equation}

which tends to zero as $\varepsilon \to 0$ in view of (4.2.4) and the Friedrichs inequality.

Second, we claim that

\begin{equation}
\int_X u^k \psi \beta \varepsilon \, d\mu_k \to 0.
\end{equation}

Since $|u^i\psi|$ is bounded, it is sufficient to show that

\begin{equation}
\int_{\Omega} |\beta \varepsilon| \, d\mu_k \to 0.
\end{equation}

Using the $\sigma_k$-property and the upper semicontinuity of eigenvalues, one obtains $\lambda^k_1(Y, \mu_k) \geq \Lambda_k$. Therefore, the limit (4.2.7) follows Proposition 3.13.

Combining (4.2.6) and (4.2.7) we obtain (4.2.3) from (4.2.5), and this completes the proof of the proposition.

\[ \square \]

Recall that $|\phi_k|^2 \equiv 1$ $dv_g$-a.e. If we informally apply $\Delta$ to this equality, using Proposition 4.10 we obtain

\[ |\nabla \phi_k|^2 dv_g = \Lambda_k \, d\mu_k \]

weakly on $G$. The goal of the next proposition is to make this computation rigorous.

**Proposition 4.12.** One has on $G$

\[ d\mu_k = \frac{|\nabla \phi_k|^2}{\Lambda_k} \, dv_g. \]

**Proof.** Let $V \subset U \subset G$ be such that $U$ satisfies $\sigma_k$-condition for all large enough $N$. It is sufficient to check that for any $\psi \in C^\infty_0(Y)$ one has

\[ \Lambda_k \int_V \psi \, d\mu_k = \int_V \psi |\nabla \phi_k|^2 \, dv_g. \]

Let $\rho_{m,i} \in C^\infty_0(U)$ be such that their restrictions to $V$ converge in $H^1(V)$ to $u_i |V$. Moreover, the family $\{\rho_{m,i}\}$ can be chosen to be equibounded. Then, by Proposition 3.13 $\rho_{m,i} |V$ converge to $u_i$ in $L^2(V, d\mu_k)$. Moreover, since $|\psi|$ and $|\nabla \psi|$ are bounded one has $\rho_{m,i} \psi \to u_i \psi$ in $H^1_0(V)$ and in $L^2(V, d\mu_k)$. Therefore, applying (4.2.3) with test function $\rho_{m,i} \psi$ and passing to the limit $m \to \infty$ yields

\[ \int_V \nabla u_i \cdot \nabla (u_i \psi) \, dv_g = \Lambda_k \int_V u_i^2 \psi \, d\mu_k \]
We then have
\[ \int_V \nabla u_i \cdot \nabla (u_i \psi) \, dv_g = \int_V |\nabla u_i|^2 \psi \, dv_g + \frac{1}{2} \int_V \nabla (u_i^2) \cdot \nabla \psi \, dv_g. \]
Summing up over \( i \) we obtain
\[ \int_V |\nabla \phi_k|^2 \psi \, dv_g + \frac{1}{2} \int_V \nabla (|\phi_k|^2) \cdot \nabla \psi \, dv_g = \Lambda_k \int_V |\phi_k|^2 \psi \, d\mu_k. \]
As \(|\phi_k|^2 = 1\) \( dv_g \)-a.e. for the second summand on the l.h.s we have
\[ \int_V \nabla (|\phi_k|^2) \cdot \nabla \psi \, dv_g = \int_V \Delta \psi \, dv_g = 0, \]
since \( \psi \in C_0^\infty (V) \). Thus we arrive at
\[ \int_V |\nabla \phi_k|^2 \psi \, dv_g = \Lambda_k \int_V |\phi_k|^2 \psi \, d\mu_k. \]
Finally, we note that by the isocapacitory inequality and \( \sigma_k \) condition, we have that for any \( F \subset V \) one has
\[ \mu_k (F) \leq \frac{1}{\Lambda_k} \text{Cap}(F, U). \]
Since \( \phi_k \) is quasicontinuous we have that \(|\phi_k|^2 = 1\) q.e. and we conclude that \(|\phi_k|^2 = 1\) \( d\mu_k \)-a.e. on \( V \), which concludes the proof. \( \square \)

**Proof of Theorem 4.1**

Substituting the expression for \( d\mu_k \) obtained in Proposition 4.12 into formula (4.2.3) we show that on the set \( G \) of good points, the map \( \phi_k \) is a weak solution of
\[ \Delta \phi_k = \frac{|\nabla \phi_k|^2}{\Lambda_k} \phi_k, \]
i.e. a weakly harmonic map to \( S^{d-1} \). By a regularity theorem of Hélein [Hel] this implies that \( \phi_k \in C^\infty (G, S^{d-1}) \).

Since \( G \) is equal to \( M \) without a finite number of points, one can apply the removable singularity theorem for harmonic maps [SU] to obtain a harmonic map \( \phi_k : M \to S^{d-1} \). Therefore,
\[ d\mu_k = \frac{|\nabla \phi_k|^2}{\Lambda_k} \, dv_g + \sum_{i=1}^k w_i \delta_{p_i}, \]
where \( p_i \) are the bad points from Proposition 4.6. This completes the proof of Theorem 4.1. \( \square \)

5. Atoms

In this section we focus on atoms arising at bad points \( p_i \). We perform a procedure reminiscent of the bubble tree construction, see e.g. [Par].

Fix a bad point \( p_i \) of weight \( w_i \). Choose a small renormalization constant \( C_R > 0 \) which will be specified later. To simplify notation, in the following we omit the subscript \( i \). Recall that we have a sequence \( N_m \to \infty \) and the
corresponding maps $\phi_{N_m,k}$. Denote by $d\nu^r$ the regular part of the measure $d\mu_k$.

5.1. **Bubble tree construction.** Assume $w > C_R$. We work in a small neighbourhood of $p$, where the metric $g$ is conformally flat. In what follows, the distances in this neighbourhood are measured with respect to the flat metric $g_0$.

Let $1 \gg \varepsilon_m > 0$ be a sequence of numbers, where $a_m \gg b_m$ means that $\frac{b_m}{a_m} \to 0$. Without loss of generality we may assume that the ball $B_m := B_{2\varepsilon_m}(p)$ can be identified with a subset of $\mathbb{R}^2$. We define $c_m = (c_m^1, c_m^2)$ to be a center of mass on the ball $B_m$

$$c_m^i = \frac{\int_{B_m} x^i d\mu_{N_m,k}}{\mu_{N_m,k}(B_m)}$$

and the scale $\alpha_m$ to be the largest number $\alpha$ such that

$$\mu_{N_m,k}(B_m \setminus B_{\alpha}(c_m)) \geq C_R.$$

**Lemma 5.1.** Up to a choice of a subsequence there exists $\delta'_m$ (see Figure 1, left) such that

- $1 \gg \varepsilon_m \gg \delta'_m \gg \alpha_m$ and $B_{\varepsilon_m}(c_m) \subset B_m$;
- $\mu_{N_m,k}(B_m) = w + o(1)$; $\mu_{N_m,k}(B_m \setminus B_{\delta'_m}(c_m)) = o(1)$.

**Proof.** Let $a_m = \frac{1}{w} \nu^r(B_m) \ll 1$ and $\delta'_m = a_m \varepsilon_m \ll \varepsilon_m$. Then $(\nu_r + w\delta_p)(B_m) = w(1 + a_m)$. Thus, for a fixed $n$ there exists $m_n$ such that for all $m \geq m_n$ one has

$$w(1 - a_m) \leq \mu_{N_m,k}(B_{\delta'_m}(p)) \leq w(1 + a_m);$$

$$\mu_{N_m,k}(B_m \setminus B_{\delta'_m}(p)) \leq 3w a_m.$$

We define a subsequence $n_l = \max(m_l, n_{l-1} + 1)$, which we rename $\{m\}$ to simplify notation. For this subsequence one has

$$w(1 - a_m) \leq \mu_{N_m,k}(B_{\delta'_m}(p)) \leq w(1 + a_m);$$

$$\mu_{N_m,k}(B_m \setminus B_{\delta'_m}(p)) \leq 3w a_m.$$

Then one has

$$\int_{B_m} |x| d\mu_{m,k} \leq \delta'_m w(1 + a_m) + 6\varepsilon_m w a_m = w(\delta'_m + \delta'_m a_m + 6\varepsilon_m a_m),$$

and, therefore,

$$|c_m| \leq \frac{\delta'_m + \delta'_m a_m + 6\varepsilon_m a_m}{1 - a_m} = b_m \ll \varepsilon_m.$$

Therefore, $c_m \in B_{\varepsilon_m}(p)$ and $B_{\varepsilon_m}(c_m) \subset B_m$.

Moreover, $b_m \leq 8\delta'_m$. In particular, $B_m \supset B_{9b_m}(c_m) \supset B_{\delta'_m}(p)$. As a result,

$$\mu_{N_m,k}(B_m \setminus B_{9b_m}(c_m)) \leq \mu_{N_m,k}(B_m \setminus B_{\delta'_m}(p)) \leq 3w a_m \ll 1.$$
Therefore, $\alpha_m \leq 9 \beta_m \ll \varepsilon_m$. Replacing $\delta'_m$ by $\max(\delta'_m, \sqrt{9 \beta_m \varepsilon_m})$ guarantees that $\alpha_m \ll \delta'_m$. □

Define $\delta_m = \sqrt{\delta'_m \varepsilon_m}$. We then have a map $R_m$ defined on $B_m$ as follows:

$$R_m(x) = \pi(\alpha_m^{-1}(x - c_m)),$$

where $\pi$ is the inverse stereographic projection from the south pole to the equatorial plane, so that $R_m(B_{\alpha_m}(c_m))$ is the northern hemisphere (see Figure 1, right). Let $\Omega_m \subset S^2$ be the image of $B_{\delta_m}(c_m)$ under $R_m$. Since $\varepsilon_m \gg \alpha_m$ one has that $\bigcup_m \Omega_m = S^2 \setminus \{S\}$, where $S$ is the south pole.

We further push-forward the measures $\mu_{N_m,k}$ by $(R_m)_*$ to measures $\tilde{\mu}_{N_m,k} = \tilde{V}_{N_m,k} d\tilde{g}_{S^2}$ and pull-back the maps $\phi_{N_m,k}$ to maps $\tilde{\phi}_{N_m,k}$ on $\Omega_m$ satisfying

$$(5.1.1) \Delta_{g_{S^2}} \tilde{\phi}_{N_m,k} = \Lambda_{k}^{N_m} \tilde{V}_{N_m,k} \tilde{\phi}_{N_m,k}.$$ 

Extend $\tilde{\mu}_{N_m,k}$ by 0 to the whole $S^2$. Let $\tilde{\mu}$ be a $*$-weak limit of $\tilde{\mu}_{N_m,k}$.

**Lemma 5.2.** The measure $\tilde{\mu}$ satisfies $\tilde{\mu}(S^2) = w$, the center of mass of $\tilde{\mu}$ is on z-axis and $\tilde{\mu}$-measure of the southern hemisphere is at least $C_R$.

**Proof.** The statement follows from Lemma 5.1 after noting the following facts. First, the center of mass for $(R_m)_*(\mu_{N_m,k}|B_m)$ is on z-axis for any $m$. Second, since $\mu_{N_m,k}(B_m \setminus B_{\delta_m}(c_m)) = o(1)$, the measures $(R_m)_*(\mu_{N_m,k}|B_m)$ and $\tilde{\mu}_{N_m,k}$ have the same $*$-weak limit. □

Define $\tau_S = \tilde{\mu}(S)$.
Lemma 5.3. Assume $\tau_S \neq 0$. Then up to a choice of a subsequence there exists $\gamma_m', \beta_m$ such that

- $\alpha_m \leq \beta_m \leq \gamma_m' \leq \delta_m'$,
- $\mu_{N_m,k}(B_{\delta_m}(c_m) \setminus B_{\gamma_m'}(c_m)) = \tau_S + o(1)$;
- $\mu_{N_m,k}(B_{\gamma_m'}(c_m) \setminus B_{\beta_m}(c_m)) = o(1)$.

Proof. Let $\bar{B}_p(S)$ be a neighbourhood of the south pole $S \in S^2$ defined as the complement of $B_{r-1}(N)$, where the distance is measured in the metric $(\pi^{-1})^* g_{\mathbb{R}^2}$.

Let $1 \gg \bar{\beta}_m \gg \gamma_m'$ and let $a_m = \bar{\mu}(\bar{B}_{\bar{\beta}_m}(S)) - \tau_S \ll 1$. Then for a fixed $n$ there exists $m_n$ such that for all $m \geq m_n$ one has

$$n\frac{\alpha_m}{\delta_m} \leq \gamma_m'$$

$$\tau_S - a_m \leq \bar{\mu}_{N_m,k}(\bar{B}_{\gamma_m'}(S)) \leq \tau_S + a_m$$

$$\bar{\mu}_{N_m,k}(\bar{B}_{\gamma_m'}(S) \setminus \bar{B}_{\bar{\beta}_m}(S)) \leq 3a_m$$

Define a subsequence $j_l = \max(m_l, j_l-1 + 1)$ and set $\beta_m = \frac{\alpha_m}{\bar{\beta}_m}$, $\gamma_m' = \frac{\alpha_m}{\bar{\gamma}_m}$. Then one has,

$$\gamma_m' = \frac{\alpha_{j_l}}{\bar{\gamma}_{j_l}} \leq \frac{\delta_{j_l}}{1};$$

$$\int_{B_{\beta_m}(c_m) \setminus B_{\gamma_m'}(c_m)} V_{N_{j_l},k} \, dv_g = \bar{\mu}_{N_{j_l},k}(\bar{B}_{\gamma_m'}(S)) = \tau_S + o(1);$$

$$\int_{B_{\gamma_m'}(c_m) \setminus B_{\beta_m}(c_m)} V_{N_{j_l},k} \, dv_g = \bar{\mu}_{N_{j_l},k}(\bar{B}_{\beta_m}(S) \setminus \bar{B}_{\gamma_m'}(S)) = o(1).$$

Renaming $\{j_l\}$ to $\{m\}$ completes the proof of the lemma. 

Set $\gamma_m = \sqrt{\gamma_m' \beta_m}$. We illustrate the construction presented above by Figure 2.

Next, we study the regularity of the measure $\bar{\mu}$. It turns out that there are two cases depending on the behaviour of the quantity $\alpha^2_m N_m$. Fix an open subset $U \subset \mathbb{S}^2 \setminus \{S\}$. We claim that if

$$\alpha^2_m N_m \to \infty,$$

then up to a choice of a subsequence, an analogue of Theorem 2.14 holds for the restrictions of $\hat{V}_{m,k}$ and $\hat{\phi}_{m,k}$ to $U$.

Proposition 5.4. Assume that the bubble $p$ is such that condition (5.1.2) holds for a strictly increasing subsequence $N_m$, $m = 1, 2, \ldots$. Then for any given open set $U \subset \mathbb{S}^2 \setminus \{S\}$ one has:

1. $\Delta_{\mathbb{S}^2} \hat{\phi}_{N_m,k} = \Lambda^N_k \hat{V}_{N_m,k} \hat{\phi}_{N_m,k}$. 
Figure 2. Decomposition of the disk $B_{δ_m}(c_m)$. The neck region (shown in green) is collapsing into the south pole as $m → ∞$ and creates the mass $τ_S$ there. The bubble region $B_{γ_m}(c_m)$ is shown in pink.

(2) The $(k + 1)$-st Dirichlet eigenvalue of the Schrödinger operator

\[ \Delta_{g^{\otimes 2}} - \Lambda^N_{V_{N,m,k}} \]

on $U$ is non-negative.

(3) $||\tilde{V}_{N,m,k}||_{L^\infty} \leq CN_m, ||\tilde{V}_{N,m,k}||_{L^1} \leq 1$.

(4) There exists a weak limit $\tilde{ϕ}_{N,m,k} → \tilde{ϕ}_k$ in $H^1(U)$ and $\tilde{ϕ}_{N_m,k} → \tilde{ϕ}_k$ in $L^2(U)$.

(5) $|\tilde{ϕ}_{N_m,k}| \leq 1$ and $|\tilde{ϕ}_k| = 1$ $dv_{g^{\otimes 2}}$-a.e.

(6) $\tilde{V}_{N_m,k} dv_{g^{\otimes 2}} \rightharpoonup^* d\tilde{μ}_U$ for some probability measure $d\tilde{μ}_U$ on $U$.

Proof. The first property is simply (5.1.1). Property (2) follows from the fact that the operator (5.1.3) on $U$ is unitary equivalent to the Schrödinger operator $\Delta - \Lambda^N_{k} V_{N,m,k}$ on $B_m$. Since the $(k + 1)$-st eigenvalue of the latter operator on $M$ is zero, by the Dirichlet bracketing the $(k + 1)$-st Dirichlet eigenvalue of (5.1.3) is non-negative.

The map $R_m$ introduces the conformal factor

\[ g^{\otimes 2} = \left( \frac{\alpha_m}{\alpha_m^2 + (x - c_m)^2} \right)^2 g_0, \]

where $g_0$ is the flat metric, locally conformal to $g$. Therefore,

\[ \tilde{V}_{N_m,k} = \left( \frac{\alpha_m}{\alpha_m^2 + (x - c_m)^2} \right)^{-2} V_{N,m,k}. \]

At the same time, since $U$ is a compact set away from the south pole,

\[ \frac{(x - c_m)}{\alpha_m} < C_U. \]
Therefore,

\[(5.1.5) \quad \left| \tilde{V}_{N_m,k} \right| \leq \alpha_m^2 V_{N_m,k},\]

and property (3) follows immediately from the analogous property in Theorem 2.14. The same is true about property (4). In property (5), the only condition to check is that \(|\tilde{\phi}_k| = 1\) holds almost everywhere in the new measure, i.e. \(dv_{g_2}\)-a.e. Indeed, the conformal factor (5.1.4) satisfies the following bound:

\[\left( \frac{\alpha_m^2}{\alpha_m^2 + (x - c_m)^2} \right)^2 \leq \alpha_m^{-2}.\]

Recall the definition (2.3.3) of the set \(E_{N_m,k}\). This set has the property that \(|\phi_k| = 1\) on its complement, and by (2.3.12) one has that \(dv_{g_0}(E_{N_m,k}) \leq C N_m^{-1}\).

Therefore, \(dv_{g_2}(U \cap R_m(B_m \cap E_{N_m})) \leq C(N_m \alpha_m^2)^{-1}\), which tends to 0 by (5.1.2).

Finally, property (6) easily follows from the compactness of the space of measures. □

We claim that Proposition 5.4 allows us to apply the regularity results of Section 4 to the measure \(\tilde{\mu}_U\). Indeed, the definitions of good and bad points are purely local as are the proofs of Propositions 4.7, 4.10 and 4.12. The only statement that is not immediate is Proposition 4.6. However, its proof can be easily modified to make use of assertion (2) of Proposition 5.4.

Thus, we can choose a subsequence such that \(\tilde{\mu}_{N_m,k}|_U \rightharpoonup \tilde{\mu}_U\), where \(\tilde{\mu}_U\) is regular outside a finite collection of points. Picking a diagonal subsequence over an exhaustion of \(S^2 \setminus S\), we have that \(\tilde{\mu} = \tilde{\mu}^r + \sum_j \tilde{w}_j \delta_{\tilde{q}_j} + \tau_S \delta_S\), \(\tilde{\mu}^r = \tilde{V}_\infty dv_{g_2}\) is a regular measure whose density is the energy density of a harmonic map to a sphere, i.e. \(\tilde{V}_\infty \in C^\infty(S^2)\). We call \(\tilde{q}_j\) secondary bubble points. Note that there are at most \(k + 1\) secondary bubbles.

We continue this procedure inductively at secondary bubbles \(\tilde{q}_j\) until one of the two things happen, either the weight \(\tilde{w}_j < C_R\) or the condition (5.1.2) fails to hold. In the former case we call \(\tilde{q}_j\) a terminal bubble. The following lemma guarantees that this process terminates after finitely many steps.

**Lemma 5.5.** One has \(\tau_S \leq C_R\), and the \(\tilde{\mu}\)-mass of the closed southern hemisphere is exactly \(C_R\) unless there are secondary bubbles on the equator. Furthermore, all secondary bubbles have mass at most \(\max(C_R, w - C_R)\).

**Proof.** By the construction of \(\alpha_m\), the mass of the open southern hemisphere is at most \(C_R\). Therefore, \(\tau_S \leq C_R\) and the mass of the closed southern hemisphere is exactly \(C_R\) unless there exists a secondary bubble \(q\) on the equator. Assume that its mass is strictly greater than \(\max(C_R, w - C_R)\).

Let \(H_q\) be an open hemisphere with center at \(q\). Since the center of mass lies on the \(z\)-axis contained in the equatorial plane generated by \(\partial H_q\), one has that the mass of the opposite hemisphere \(S^2 \setminus \overline{H_q}\) is at least the mass...
of the bubble \( q \), i.e. the total mass \( w = \tilde{\mu}(S^2) > 2 \max(C_R, w - C_R) > w \), which is a contradiction.

Assume that there is a secondary bubble of mass strictly greater than \( \max(C_R, w - C_R) \) somewhere. Then it cannot be in the open southern hemisphere since its mass is at most \( C_R \). The previous argument shows that it cannot be on the equator. Thus, it is in the open northern hemisphere. But the mass of the closed southern hemisphere is at least \( C_R \), so we obtain a contradiction with the fact that the total mass of the bubble is equal to \( w \). \( \square \)

Let us now assume that the initial bubble \( p \) does not satisfy the condition (5.1.2), i.e. up to a choice of a subsequence \( \alpha^2 m N_m = O(1) \). In this case by inequality (5.1.5) the potentials \( \tilde{V}_{N_m,k} \) are uniformly bounded on any given open set \( U \subset S^2 \setminus \{S\} \). Therefore, once again one could choose a diagonal subsequence and imply that there exists a \(*\)-weak limit \( \tilde{V}_\infty \in L^1(S^2) \) such that \( \tilde{V}_{N_m,k} \to ^* \tilde{V}_\infty \) for all \( U \subset S^2 \setminus \{S\} \). In particular, the bubble tree construction stops at such bubbles since there are no secondary bubbles, only a possible mass concentration near the south pole. We see that at any non-terminal bubble (regardless the behaviour of \( \alpha^2 m N_m \)) the measure \( \tilde{\mu} \) is regular up to possible concentration at finitely many atoms.

Let us now describe the construction of the bubble tree. The root of the tree is the surface \( M \), and its direct descendants are the atoms \( p_i \). As described above, each atom gives rise to bubbles, and each bubble, after appropriate rescaling may give rise to secondary bubble points, and so on. Each branch of the tree stops at a terminal bubble, and in view of Lemma 5.5 the bubble tree is finite. We summarize its properties in the following theorem.

**Theorem 5.6 (Bubble tree).** For any non-terminal bubble \( b \) there exists a point \( p^b \in M \), a sequence of points \( c^b_m \to p^b \) and a sequence of scales

\[
\alpha^b_m \ll \gamma^b_m \ll \delta^b_m \ll \varepsilon^b_m \ll 1
\]

and for any terminal bubble \( b \) there exists a sequence of sequence of points \( c^b_m \to p^b \) and a sequence of scales

\[
\delta^b_m \ll \varepsilon^b_m \ll 1
\]

such that

1) Any two bubbles \( b_1, b_2 \) are either away from one another or one of them is a descendent of the other. In the former case one has that the intersection \( B_{\varepsilon^b_m}(c^b_m) \cap B_{\varepsilon^b_m}(c^b'_m) \) is empty. In the latter case, \( b_1 \) is secondary to \( b_2 \) or \( b_1 \prec b_2 \) if \( p^{b_1} = p^{b_2}, \varepsilon^b_m \ll \alpha^b_m \) and \( B_{\varepsilon^b_m}(c^b_m) \subset B_{\beta^b_m}(c^b'_m) \).
2) As $m \to \infty$, the following asymptotic relations hold:
\[
\mu_{m,k}(B_{\gamma_m}(c_m) \setminus B_{\beta_m}(c_m) \cup B_{\delta_m}(c_m) \setminus B_{\epsilon_m}(c_m)) = o(1),
\]
\[
\mu_{m,k}(B_{\delta_m}(c_m) \setminus B_{\gamma_m}(c_m)) = \tau_{S} + o(1),
\]
where $\tau_{S} \leq C_R$.

3) Let $M_m = M \setminus \bigcup_b B_{\delta_m}(c_m)$. Then
\[
\mu_{m,k}|_{M_m} \rightharpoonup^* V_\infty dv_g,
\]
where $V_\infty \in C^\infty(M)$. We will refer to $M_m$ as the regular region.

4) Set $R_m^b(x) = \pi((a_m^b)^{-1}(x-c_m^b))$ and define the bubble region $B_m(b) = B_{\gamma_m}(c_m) \setminus \bigcup_{a^b < b} B_{\delta_m}(c_m)$. Then
\begin{equation}
(R_m^b)^* \mu_{m,k}|_{B_m(b)} \rightharpoonup^* V_\infty^b dv_{g_2},
\end{equation}
where $V_\infty^b \in L^1(S^2)$ and for any $U \Subset S^2 \setminus \{S\}$ one has $V_\infty^b|_U \in L^\infty(U)$.

**Definition 5.7.** We say that the bubble $b$ is of type I if $V_\infty^b \in L^\infty(S^2)$. Otherwise, we say that the bubble $b$ is of type II.

**Remark 5.8.** The real difference between type I and type II bubbles arises if $V_\infty^b \notin L^p(S^2)$ for any $p > 1$, since in this case one can not guarantee that the spectrum of the corresponding Laplacian is discrete (see [Kok2, Section 2.3] for a discussion).

For Type II bubbles one needs to modify the scales obtained in Proposition 5.6 in the way described below, see also Figure 3 for an illustration.

![Figure 3. Fine structure of a type II bubble. The outer ring $A_m^b$ contains an amount of mass bounded below by (5.1.8).](image-url)
Proposition 5.9. Let \( b \) be a bubble of type II. Then one can redefine \( \beta_m^b \) and additionally find \( \omega_m^b \) such that
\[
\alpha_m^b \ll \omega_m^b \ll \beta_m^b \ll \gamma_m^b
\]
and the following holds. Define \( A_1^b(m) = B_{\alpha_m^b}(c_{m}^b) \setminus B_{\omega_m^b}(c_{m}^b) \), which is a part of the bubble region, and a “collar region” \( A_2^b(m) = B_{\gamma_m^b}(c_{m}^b) \setminus B_{\beta_m^b}(c_{m}^b) \). Then
\[
(5.1.7) \quad \mu_{m,k}(A_i^b(m)) = o(1)
\]
for \( i = 1, 2 \) as \( m \to \infty \), and
\[
(5.1.8) \quad \mu_{m,k}(A_2^b(m)) \gg \sum a \left( \frac{1}{\sqrt{\ln \gamma_m^{a^b} / \omega_m^{a^b}}} + \frac{1}{\sqrt{\ln \delta_m^{a^b} / \gamma_m^{a^b}}} + \frac{1}{\sqrt{\ln \varepsilon_m^{a^b} / \delta_m^{a^b}}} \right) + \sum a \text{ is of type I} \frac{1}{\sqrt{\ln \gamma_m^{a^b} / \beta_m^{a^b}}}.
\]

Proof. Let \( \tilde{B}_r(S) \) be a neighbourhood of the south pole \( S \in S^2 \) defined as the complement of \( B_{r-1}(N) \), where the distance is measured in the metric \( (\pi^{-1})^* g_{S^2} \). Set
\[
f(r) = \int_{\tilde{B}_r(S)} \tilde{V}_b^b \, dv_{g_{S^2}}.
\]
Since \( \tilde{V}^b_{\infty} \notin L^\infty(\tilde{B}_r(S)) \) for any \( r \), it is nonzero almost everywhere is some neighborhood of \( S \), and therefore \( f \) is a non-decreasing function satisfying \( f(r) > 0 \) for \( r > 0 \). Fix a small \( r_0 > 0 \). Let \( \nu_m \) be the square root of the r.h.s of (5.1.8), then \( \nu_m = o(1) \) and for large enough \( m \) one has \( \nu_m \leq f(r_0) \).

For such \( m \) we define
\[
\tilde{\beta}_m = \min \{ r \mid f(r) = \nu_m \}
\]
and set \( \tilde{\omega}_m = \sqrt{\tilde{\beta}_m} \). Then \( 1 \gg \tilde{\omega}_m \gg \tilde{\beta}_m \). Set \( \tilde{\gamma}_m = \alpha_m^b / \tilde{\beta}_m \) so that \( \partial \tilde{B}_{\tilde{\gamma}_m}(S) = \partial R_m(\tilde{B}_{\omega_m^b}(c_{m}^b)) \). For a fixed \( n \) there exists \( m_n \) such that for all \( m \geq m_n \) one has the following,
\[
n \tilde{\gamma}_m \leq \tilde{\beta}_n;
\]
\[
\tilde{\mu}_{n,m,k}(\tilde{B}_{\tilde{\beta}_n}(S) \setminus \tilde{B}_{\tilde{\gamma}_m}(S)) \geq \frac{1}{2} \int_{\tilde{B}_{\tilde{\beta}_n}(S)} \tilde{V}_b^b \, dv_{g_{S^2}} = \frac{1}{2} \nu_n \geq \nu_m;
\]
\[
\tilde{\mu}_{n,m,k}(\tilde{B}_{\tilde{\omega}_n}(S) \setminus \tilde{B}_{\tilde{\gamma}_m}(S)) \leq 2 \int_{\tilde{B}_{\tilde{\omega}_n}(S)} \tilde{V}_b^b \, dv_{g_{S^2}} \xrightarrow{n \to \infty} 0
\]
Define a subsequence \( j_l = \max(m_l, j_{l-1} + 1) \) and set \( \beta_{j_l}^b = \frac{\alpha_{j_l}^b}{\beta_l}, \omega_{j_l}^b = \frac{\alpha_{j_l}^b}{\omega_l} \).

After elementary calculations, the previous inequalities become

\[
(5.1.9) \quad l\beta_{j_l}^b \leq \gamma_{j_l}^b
\]

\[
(5.1.10) \quad \mu_{j_l,k}(A_{j_l}^2(b)) \geq l_{j_l}
\]

\[
(5.1.11) \quad \mu_{j_l,k}(A_{j_l}^1(b) \cup A_{j_l}^2(b)) \xrightarrow{\ell \to \infty} 0
\]

Let us rename the subsequence \( \{j_l\} \) to \( \{m_l\} \). Then (5.1.9) implies that \( \gamma_m \gg \beta_m \). (5.1.10) implies (5.1.8) and (5.1.11) implies (5.1.7). This completes the proof of the proposition. \( \square \)

5.2. Construction of test-functions. In this section we describe the test-space for \( \lambda_i(V_{N_m,k}) \). Let us introduce some notation. In addition to the bubble region \( \mathcal{B}_m(b) \) and the regular region \( M_m \) introduced in Theorem 5.6, we set \( M'_m = M \setminus \bigcup_b B_{\gamma_m}(c_m^b), \mathcal{B}'_m(b) = B_{\rho_m}(c_m^b) \setminus \bigcup_b B_{\epsilon_m}(c_m^b) \), and introduce the neck regions \( \mathcal{A}_m(b) = B_{\delta_m}(c_m^b) \setminus B_{\epsilon_m}(c_m^b), \mathcal{A}'_m(b) = B_{\delta_m}(c_m^b) \setminus B_{\epsilon_m}(c_m^b) \). For terminal bubbles we set \( \mathcal{A}_m(b) = \mathcal{B}_m(b) = B_{\rho_m}(c_m^b) \) and \( \mathcal{A}'_m(b) = \mathcal{B}'_m(b) = B_{\rho_m}(c_m^b) \).

First, we construct test-functions supported in \( M_m \). For that we take the eigenfunctions for \( (M, V_{\infty}) \) and multiply them by a logarithmic cut-off function \( \rho_m^M \in C_0^\infty(M_m) \) equal to 1 on \( M'_m \). We denote such a space of test-functions constructed from the first \( j \) eigenfunctions (including constants) by \( F_j^M \).

Similarly, we define test-functions supported in the bubble region \( \mathcal{B}_m(b) \) for a type I bubble \( b \). We take the eigenfunctions for \( (S^2, V_{b}^1) \), transplant them to \( M \) and multiply them by a logarithmic cut-off function \( \rho_m^b \in C_0^\infty(B_m(b)) \) equal to 1 on \( \mathcal{B}_m(b) \). We denote such a space of test-functions constructed from the first \( j \) eigenfunctions (including constants) by \( F_j^b \).

For each terminal bubble \( b \) we simply use the logarithmic cut-off function \( \rho_m^b \in C_0^\infty(\mathcal{A}_m(b)) \) equal to 1 on \( \mathcal{A}'_m(b) \). Similarly, for each neck region with non-zero mass on any bubble \( b \) we use the logarithmic cut-off \( \tau_m^b \in C_0^\infty(\mathcal{A}_m(b)) \) equal to 1 on \( \mathcal{A}'_m(b) \). We denote the space spanned by these functions by \( F_{\text{neck}} \). Note that \( \dim F_{\text{neck}} \) is equal to the number \( t \) of terminal bubbles and necks of non-zero mass.

The situation for type II bubbles is more complicated. In particular, the test-functions associated with type II bubbles are not supported on that bubble, but rather equal constant outside the bubble. Let \( b \) a type II bubble. First of all we modify the potential \( V_{N_m,k} \) to be equal to 0 on \( A_{N_m,k}^1(b) \). This only increases the eigenvalues and does not change the behaviour as \( m \to \infty \) since \( \mu_{N_m,k}(A_{N_m,k}^1(b)) \to 0 \).
Set $\mathcal{B}_m''(b) = B_{\omega_m}(c_m^b)$. Let $\tilde{V}_m^b$ be a potential on $S^2$ defined by

\begin{equation}
(5.2.1) \quad \tilde{V}_m^b dv_{S^2} = \begin{cases} (R^b_m)_*(V_{N_m,k} \, dv_g) & \text{on } R_m^b(\mathcal{B}_m''(b)) \\ 0 & \text{otherwise} \end{cases}
\end{equation}

Let $\psi^b_m$ be a linear combination of the eigenfunctions of $(S^2, \tilde{V}_m^b)$. In particular, $\psi^b_m$ is harmonic on the complement to $R_m^b(\mathcal{B}_m''(b))$. Let $\theta^b_m \in C_0^\infty(R_m^b(B_{\beta_m}(c_m^b)))$ be a cut-off function equal to 1 on $R_m^b(B_{2\omega_m}(c_m^b))$.

Define

\begin{equation}
(5.2.2) \quad \tilde{\psi}_m^b = (\psi^b_m - \psi^b_m(S))\theta^b_m + \psi^b_m(S),
\end{equation}

where $S$ is the South pole.

The following proposition shows that the Rayleigh quotients of the functions $\tilde{\psi}_m^b$ and $\psi^b_m$ are close as $m \to \infty$.

**Proposition 5.10.** As $m \to \infty$, we have the inequality

\begin{equation}
(5.2.3) \quad \int_{S^2} |\nabla \tilde{\psi}_m^b|^2 \leq (1 + o(1)) \int_{S^2} |\nabla \psi^b_m|^2.
\end{equation}

Also, for any $m$,

\begin{equation}
(5.2.4) \quad \int_{S^2} (\tilde{\psi}_m^b)^2 \tilde{V}_m^b dv_{S^2} = \int_{S^2} (\psi^b_m)^2 \tilde{V}_m^b dv_{S^2}.
\end{equation}

**Proof.** The equality (5.2.4) is immediate, since $\tilde{\psi}_m^b = \psi^b_m$ on the support of $\tilde{V}_m^b$. To prove the inequality we note that

\begin{equation}
(5.2.5) \quad u = \psi^b_m - \psi^b_m(S)
\end{equation}

is harmonic on the annulus $R_m^b(A^1_m(b))$. The nodal line of $u$ passes through $S$. By maximum principle the nodal set can not contain a closed arc outside $R_m^b(\mathcal{B}_m''(b))$, therefore the nodal set goes all the way from $S$ to $R_m^b(\partial \mathcal{B}_m''(b))$. We will use the following lemma.

**Lemma 5.11.** There exists a universal constant $C$ such that

\begin{equation}
\|u\|_{L^\infty(\bar{A}^1_m(b))}^2 \leq C \int_{A^1_m(b)} |\nabla u|^2,
\end{equation}

where $\bar{A}^1_m(b) = B_{2\omega_m}(c_m^b) \setminus B_{\beta_m}(c_m^b) \subset A^1_m(b)$.

**Proof of Lemma 5.11.** Let $x$ be a point where $|u|$ achieves the maximum on $\bar{A}^1_m(b)$. Assume for simplicity of notations that the coordinates are chosen in such a way that $c_m^b = 0$. Then the nodal line of $u$ intersects both boundary components of the annulus $B_{2|x|}(0) \setminus B_{\frac{1}{2}|x|}(0)$. We will show that

\begin{equation}
(5.2.6) \quad |u(x)| \leq C \int_{B_{2|x|}(0) \setminus B_{\frac{1}{2}|x|}(0)} |\nabla u|^2,
\end{equation}

which obviously implies the required inequality.
Note that both sides of the inequality (5.2.6) are scale-invariant. Therefore, without loss of generality, we may assume that \(|x| = 2\). Since the nodal line intersects both boundary components, one has that

\[
\int_{B_4(0) \setminus B_1(0)} u^2 \leq C \int_{B_4(0) \setminus B_1(0)} |\nabla u|^2.
\]

Indeed, for each \(\rho \in [1, 4]\) let \(x_\rho \in \partial B_\rho\) be a point such that \(u(x_\rho) = 0\). Let \(s\) be a natural parameter along \(\partial B_\rho\), i.e. \(s = \frac{\rho}{2\pi}\) in polar coordinates. Then one has

\[
\int_{S_\rho} u^2 = \int_{S_\rho} \left( \int_{x_\rho}^s \partial_s u(\rho, s) \, ds \right)^2 \leq \int_{S_\rho} \left( 2\pi \rho \int_{S_\rho} |\partial_s u(\rho, s)|^2 \, ds \right) \leq (2\pi)^2 \int_{S_\rho} |\nabla u|^2.
\]

Therefore, one has on \(A = B_4 \setminus B_1\) that

\[
\int_A u^2 = \int_1^4 \left( \int_{S_\rho} u^2 \right) \, d\rho \leq \int_1^4 (2\pi \rho)^2 \int_{S_\rho} |\nabla u|^2 \, d\rho \leq 64\pi^2 \int_A |\nabla u|^2,
\]

which proves inequality (5.2.7).

As was mentioned above, \(u\) is harmonic in \(A_1^{1m}(b)\). Therefore, \(u^2\) is subharmonic, and hence

\[
u^2(x) \leq \frac{1}{\pi} \int_{B_1(x)} u^2 \leq \frac{1}{\pi} \int_{B_4(0) \setminus B_1(0)} u^2 \leq C \int_{B_4(0) \setminus B_1(0)} |\nabla u|^2.
\]

Here in the first inequality we used the mean value theorem, and in the second inequality the inclusion \(B_1(x) \subset B_4(0) \setminus B_1(0)\), which follows from the normalization \(|x| = 2\). This completes the proof of Lemma 5.11. \(\square\)

Let us continue with the proof of Proposition 5.10. Let \(\alpha_m > 0\) be a number to be chosen later. Combining the Cauchy-Schwarz inequality with the arithmetic-geometric mean inequality and using (5.2.2), we obtain for any \(\alpha_m > 0\):

\[
(5.2.8) \quad \int_{S^2} |\nabla \psi^b_m|^2 \leq (1 + \alpha_m) \int |\nabla \psi^b_m|^2 (\theta^b_m)^2 + \left( 1 + \frac{1}{\alpha_m} \right) \int u^2 |\nabla \theta^b_m|^2,
\]

where \(u\) is defined by (5.2.5). Note that by construction \(\text{supp}(\nabla \theta^b_m) \subset \bar{A}_m^{1m}(b)\). Therefore, using Lemma 5.11 to estimate the second term and taking into account that \(\theta^b_m \leq 1\) to estimate the first one, we get:

\[
\int_{S^2} |\nabla \psi^b_m|^2 \leq \left( 1 + a_m + C \left( 1 + \frac{1}{\alpha_m} \right) \int |\nabla \theta^b_m|^2 \right) \int |\nabla \psi^b_m|^2.
\]

Setting \(\alpha_m = (\int |\nabla \theta^b_m|^2)^{1/2}\), and noting that with this choice \(\alpha_m = o(1)\) by Section 3.4 completes the proof of Proposition 5.10. \(\square\)
Let us now define the space of test-functions associated with a type II bubble. We denote by $E^b_j$ the space of test-functions $\tilde{\psi}_m^b$ constructed from the functions $\psi_m^b$ which are represented as linear combinations of the first $j$ eigenfunctions orthogonal to constants. Note that by our construction, if one takes the constant function on the type II bubble, then it yields a constant function on $M$, i.e. constant test-functions on different type II bubbles yield the same test-function on $M$. To compensate for that we need to add $(s-1)$ functions, where $s$ is the number of type II bubbles. For $(s-1)$ of those bubbles we add a logarithmic cut-off $\rho_m^b \in C_0^\infty(B_{\gamma_m}(c_m^b))$ which is equal to 1 on $B_{\gamma_m}(c_m^b)$. We denote by $\tilde{a}$ the remaining type II bubble and by $E$ the $s$-dimensional space spanned by 1 and these $(s-1)$ functions.

5.3. Eigenvalue bounds. In the notation of the previous subsection, let

$$F = F_{j+1}^M \bigoplus_{b \text{ of type I}} F_{j+1}^b \bigoplus_{a \text{ of type II}} E^a_j \oplus F_{\text{neck}} \oplus E$$

for some fixed natural numbers $j, j_a$ and $j_b$, where the index $b$ runs over all bubbles of type I, and the index $a$ runs over all bubbles of type II.

Proposition 5.12. For any given given natural numbers $k, j, j_a, j_b$, where the index $b$ runs over all bubbles of type I, and the index $a$ runs over all bubbles of type II,

$$\lambda_{\dim F - 1}(M, V_{N_m, k}) \leq \max_{b \text{ of type I}, a \text{ of type II}} \{\lambda_j(M, V_{\infty}), \lambda_{j_b}(S^2, \tilde{V}_b^\infty), \lambda_{j_a}(S^2, \tilde{V}_a^\infty)\} + o(1).$$

Proof. Let $u \in F$. Then there exists a constant $D_m$ such that for any bubble $b$ of type I

$$u_m = \begin{cases} 
\psi^M_m & \text{on } M'_m \\
\rho^M_m \psi^M_m + (1 - \rho^M_m) D_m & \text{on } M_m \setminus M'_m \\
\psi^b_m & \text{on } B_{\rho'_m}(b) \\
\rho^b_m \psi^b_m + (1 - \rho^b_m) D_m & \text{on } B_m(b) \setminus B'_m(b),
\end{cases}$$

where $\psi^M$ and $\psi^b$ are linear combinations of the first $j + 1$ eigenfunctions of $(M, V_\infty)$ and the first $j_b + 1$ eigenfunctions of $(S^2, \tilde{V}_b^\infty)$, respectively (in both cases, the constants are included). Furthermore, for any bubble $b$ of type I with neck of non-zero mass or a terminal bubble one has

$$u_m = \begin{cases} 
C^b_m & \text{on } A'_m(b) \\
\tau^b_m C^b_m + (1 - \tau^b_m) D_m & \text{on } A_m(b) \setminus A'_m(b),
\end{cases}$$
where \( C^b \) are some constants. If the neck mass is zero, then \( u = D_m \) on \( A_m(b) \). Finally, for type II bubbles \( a \) with non-zero mass neck one has

\[
(5.3.3) \quad u_m = \begin{cases} 
\tilde{\psi}_m^a & \text{on } B'_m(a) \\
D_m^a & \text{on } A^2_m(a) \\
C^a \rho_m^a + D_m^a(1 - \rho_m^a) & \text{on } B_{\gamma_m}(c_m^a) \setminus B_{\gamma_m}(e_m^a) \\
C^a \tau_m^a + D_m(1 - \tau_m^a) & \text{on } B_{\gamma_m}(c_m^a) \setminus B_{\gamma_m}(e_m^a),
\end{cases}
\]

where \( D_m^a = D_m \) and \( \tilde{\psi}_m^a \) is obtained by the cut-off construction from a linear combination \( \psi_m^a \) of the first \( j_a + 1 \) eigenfunctions of \((S^2, \tilde{V}_m^a)\) defined by \([5.2.2]\). Finally, for type II bubble \( a \) with zero mass neck one has

\[
(5.3.4) \quad u_m = \begin{cases} 
\tilde{\psi}_m^a & \text{on } B'_m(a) \\
D_m^a & \text{on } A^2_m(a) \\
D_m \rho_m^a + D_m^a(1 - \rho_m^a) & \text{on } B_{\gamma_m}(c_m^a) \setminus B_{\gamma_m}(e_m^a).
\end{cases}
\]

We are now ready to estimate the Rayleigh quotient of \( u \). We do it step by step.

1. **On** \( M_m \). Since the space \( F^{M}_{j+1} \) is finite dimensional, there exists a constant \( C_j \) such that for any \( x \in M_m \),

\[
(5.3.5) \quad |\psi^M(x)|^2 \leq C_j \int_M (\psi^M)^2 V_\infty.
\]

Then we have for any \( 0 \leq \delta \leq 1 \):

\[
\int_{M_m \setminus M_m'} |\nabla u|^2 \leq
\int_{M_m \setminus M_m'} (1 + 2\delta)(\rho_m^M)^2 |\nabla \psi^M|^2 + (1 + \delta + \frac{1}{\delta})(\psi^M)^2 |\nabla \rho_m^M|^2 + (1 + \frac{2}{\delta}) D_m^2 |\nabla \rho_m^M|^2 \leq
(1 + 2\delta) \int_{M_m \setminus M_m'} |\nabla \psi^M|^2 + (1 + \frac{2}{\delta}) \int_{M_m \setminus M_m'} |\nabla \rho_m^M|^2 C \int_M (\psi^M)^2 V_\infty + (1 + \frac{2}{\delta}) D_m^2 \int |\nabla \rho_m^M|^2
\]

Here the first inequality follows, similarly to \([5.2.8]\), from the Cauchy-Schwarz inequality combined with the arithmetic-geometric mean inequality. Set \( \delta = \sqrt{\int |\nabla \rho_m|^2} = o(1) \). This yields

\[
\int_{M_m} |\nabla u|^2 \leq (1 + o(1)) \int_{M_m} |\nabla \psi^M|^2 + o(1) \int_M (\psi^M)^2 V_\infty + (2 + o(1)) D_m^2 \sqrt{\int |\nabla \rho_m^M|^2} \leq \lambda_j(M, V_\infty)(1 + o(1)) \int_M (\psi^M)^2 V_\infty + I_m^M,
\]
where
\[ I_m^M = (2 + o(1))D^2_m \sqrt{\int |\nabla \rho^M_m|^2}. \]

Note that by construction the space \( F_{j+1} \) is generated by the first \( j + 1 \) eigenfunctions including constants, and hence the \( j \)-th nonzero eigenvalue \( \lambda_j \) appears on the right-hand side of the inequality. At the same time, using (5.3.5) one has

\[
(5.3.6) \left| \int_M (\psi^M)^2 V_\infty - \int_{M'_m} (\psi^M)^2 V_{N_m,k} \right| \leq 
\left( C_j \int_M (\psi^M)^2 V_\infty \right) \left| \int_M V_\infty - \int_{M'_m} V_{N_m,k} \right| \leq o(1) \int_M (\psi^M)^2 V_\infty
\]

Here in the last inequality we used the third assertion of Theorem 5.6 as well as the fact that by construction \( \mu_{m,k}(M_m \setminus M'_m) = o(1) \). Putting everything together and taking into account that \( u|_{M'_m} = \psi^M \), we have that

\[
\int_{M_m} |\nabla u|^2 \leq \lambda_j(M, V_\infty)(1 + o(1)) \int_{M_m} u^2 V_{N_m,k} + I_m^M.
\]

The term \( I_m^M \) will be dealt with later.

2. On \( B_m(b) \). The same argument follows through on \( B_m(b) \) for type I bubbles \( b \). One has

\[
\int_{B_m(b)} |\nabla u|^2 \leq \lambda_j(S^2, V_\infty^b)(1 + o(1)) \int_{B_m(b)} u^2 V_{N_m,k} + I^b_m,
\]

where
\[ I^b_m = (2 + o(1))D^2_m \sqrt{\int |\nabla \rho^b_m|^2}. \]

3. On \( A_m(b) \) for type I bubbles. On the neck regions \( A_m(b) \) of nonzero mass for type I bubbles and terminal bubbles one has

\[
\int_{A_m(b)} |\nabla u|^2 \leq (1 + \delta)(C^b)^2 \int |\nabla \tau^b_m|^2 + \left( 1 + \frac{1}{\delta} \right) D^2_m \int |\nabla \tau^b_m|^2.
\]

Since
\[
\int_{A'_m(b)} u^2 V_{N_m,k} = (C^b)^2(\tau^b_S + o(1)).
\]
Setting $\delta = \sqrt{\int |\nabla \tau^b_m|^2}$ one has
\[
\int_{A_m(b)} |\nabla u|^2 \leq o(1) \int_{A_m(b)} u^2 V_{N_m,k} + J^b_m,
\]
where
\[
J^b_m = (2 + o(1)) D^2_m \sqrt{\int |\nabla \tau^b_m|^2}.
\]

4. On $A_m(a)$ for type II bubbles. Similar argument on the neck regions $A_m(a)$ for type II bubbles (this bound holds for both zero and non-zero mass of the neck) yields
\[
\int_{A_m(a)} |\nabla u|^2 \leq o(1) \int_{A_m(a)} u^2 V_{N_m,k} + J^a_m + K^a_m,
\]
where
\[
J^a_m = (2 + o(1)) D^2_m \sqrt{\int |\nabla \tau^a_m|^2}; \quad K^a_m = (2 + o(1)) (D^2_m)^2 \sqrt{\int |\nabla \rho^a_m|^2}.
\]

5. On $B'_m(a)$ for type II bubbles. By the construction of test-functions one has
\[
\int_{B'_m(a)} |\nabla u|^2 \leq (\lambda_j (S^2, \tilde{V}^a_m) + 1) \int_{B'_m(a)} u^2 V_{N_m,k}
\]

6. Dealing with $I, J, K$ terms. We note that by condition (5.1.8) and the estimate in Section 3.4 one has
\[
\sum_a (I^a_m + J^a_m) + K^a_m \ll D^2_m \int_{A^2_m(a)} V_{N_m,k} = \int_{A^2_m(a)} u^2 V_{N_m,k}.
\]
Similarly, for type II bubble $a \neq \tilde{a}$ one has
\[
K^a_m \ll (D^2_m)^2 \int_{A^2_m(a)} V_{N_m,k} = \int_{A^2_m(a)} u^2 V_{N_m,k}.
\]

Summing all these terms together completes the proof of Proposition 5.12.

Let $w_M = \int_M V_\infty$ be the area of the regular part of the surface $M$. If $w_M \neq 0$, then define $d_M$ by
\[
\lambda_{d_M}(M, V_\infty) < \Lambda_k(M, C) \leq \lambda_{d_{M+1}}(M, V_\infty).
\]
Similarly, for all type I bubbles $b$ we set $w_b = \int_{S^2} \tilde{V}^b_\infty dv_{g_2}$, where $\tilde{V}^b_\infty$ is defined by (5.1.6). For each $b$ such that $w_b > 0$, define $d_b$ by
\[
\lambda_{d_b}(S^2, \tilde{V}^b_\infty) < \Lambda_k(M, C) \leq \lambda_{d_{b+1}}(S^2, \tilde{V}^b_\infty).
\]
Finally, for any type II bubble $a$ let $w_a^m = \int_{\mathbb{S}^2} \tilde{V}_m^a \, dv_{g_2}$, where $\tilde{V}_m^a$ is defined by (5.2.1). Set $w_a = \lim_{m \to \infty} w_a^m$; note that the limit exists due to (5.1.7).

For any type II bubble $a$ such that $w_a > 0$, define $d_a$ by

\[(5.3.8) \quad \limsup_{m \to \infty} \lambda_{d_a}(\mathbb{S}^2, \tilde{V}_m^a) < \Lambda_k(M, C) \leq \limsup_{m \to \infty} \lambda_{d_a+1}(\mathbb{S}^2, \tilde{V}_m^a).\]

Let $t$ be the number of necks of non-zero mass and terminal bubbles, and recall that we have assumed that the total area of the surface $M$ is equal to one.

**Proposition 5.13.** One has

\[(d_M + 1) + \sum_{b: \ w^b \neq 0} (d_b + 1) + \sum_{a: \ w^a \neq 0} (d_a + 1) + t \leq k.\]

In particular, $t \leq k$.

**Proof.** We argue by contradiction. Assume that

\[(d_M + 1) + \sum_{b: \ w^b \neq 0} (d_b + 1) + \sum_{a: \ w^a \neq 0} (d_a + 1) + t > k + 1.\]

Then by Proposition 5.12 one has

\[\lambda_k(M, V_{N_m,k}) \leq \max\{\lambda_{d_M}(M, V_\infty), \lambda_{d_b}(\mathbb{S}^2, \tilde{V}_\infty^b), \lambda_{d_a}(\mathbb{S}^2, \tilde{V}_m^a)\} + o(1).\]

Passing to the lim sup as $m \to \infty$ and using the definition of $d_M, d_a, d_b$ one has

\[\Lambda_k(M, C) \leq \max\{\lambda_{d_M}(M, V_\infty), \lambda_{d_b}(\mathbb{S}^2, \tilde{V}_\infty^b), \limsup \lambda_{d_a}(\mathbb{S}^2, \tilde{V}_m^a)\} < \Lambda_k(M, C).\]

We can now complete the proof of the main result of the paper.

**Proof of Theorem 1.1.** Let, as before, $M$ be a surface with a fixed conformal class $C$. Using the fact that $t \leq k$ one has

\[w_M + \sum_{b \text{ is not terminal}} w_b + \sum_{a \text{ is not terminal}} w_a \geq 1 - kC_R.\]

Thus, summing up the inequalities

\[w_M \Lambda_k(M, C) \leq w_M \lambda_{d_M+1}(M, V_\infty) \leq \Lambda_{d_M+1}(M, C)\]
\[w_b \Lambda_k(M, C) \leq w_b \lambda_{d_b+1}(\mathbb{S}^2, \tilde{V}_\infty^b) \leq \Lambda_{d_b+1}(\mathbb{S}^2)\]
\[w_a \Lambda_k(M, C) \leq w_a \limsup \lambda_{d_a+1}(\mathbb{S}^2, \tilde{V}_m^a) \leq \Lambda_{d_a+1}(\mathbb{S}^2).\]

yields, provided $w_M > 0$,

\[(1 - kC_R) \Lambda_k(M, C) \leq \Lambda_{d_M+1}(M, C) + \sum_{b: \ w^b \neq 0} \Lambda_{d_b+1}(\mathbb{S}^2) + \sum_{a: \ w^a \neq 0} \Lambda_{d_a+1}(\mathbb{S}^2) \leq \max \{\Lambda_k(M) + \Lambda_{k-k'}(\mathbb{S}^2)\},\]
where \(1 \leq k' < k\) if there is at least one bubble of non-zero mass. Since the choice of \(C_R\) is arbitrary, passing to the limit \(C_R \to 0\) we obtain:

\[
(5.3.9) \quad \Lambda_k(M) \leq \max_{1 \leq k' < k} \{ \Lambda_{k'}(M) + \Lambda_{k-k'}(S^2) \}.
\]

At the same time, it was shown in [KNPP] that \(\Lambda_j(S^2) = 8\pi j\) for any \(j \geq 1\). Thus, if

\[
\Lambda_k(M, C) > \max_{k' < k} \{ \Lambda_{k'}(M, C) + 8\pi(k - k') \} = \Lambda_{k-1}(M, C) + 8\pi
\]

then there are no bubbles and hence there exists a metric \(h\) smooth outside of isolated conical singularities such that \(\Lambda_k(M) = \hat{\lambda}_k(M, h)\). This proves the second assertion of Theorem 1.1 provided \(w_M > 0\). If \(w_M = 0\) then instead of (5.3.9) we would get

\[
(5.3.10) \quad \Lambda_k(M) \leq 8\pi k.
\]

In view of (1.1.5) and [CES, Theorem B] it follows that \(M\) is a sphere and (5.3.10) is an equality. Moreover, it follows from the results of [KNPP] that (1.1.3) holds.

Finally, for \(k = 1\), Proposition 5.13 implies that only one of the weights \(w_M, w_b, w_a\) could possibly be non-zero. If \(w_M \neq 0\), then there are no bubbles and we obtain the existence of a regular conformally maximal metric. If one of the bubbles has a non-zero mass, then by (5.3.10) one has

\[
\Lambda_1(M, C) \leq 8\pi,
\]

which once again implies that \(M\) is a sphere. This completes the proof of Theorem 1.1.

\[\square\]
