Constrained rough paths

Thomas Cass, Bruce K. Driver and Christian Litterer

Abstract
We introduce a notion of rough paths on embedded submanifolds and demonstrate that this class of rough paths is natural. On the way, we develop a notion of rough integration and an efficient and intrinsic theory of rough differential equations (RDEs) on manifolds. The theory of RDEs is then used to construct parallel translation along manifold-valued rough paths. Finally, this framework is used to show that there is a one-to-one correspondence between rough paths on a \( d \)-dimensional manifold and rough paths on \( d \)-dimensional Euclidean space. This last result is a rough path analogue of Cartan’s development map and its stochastic version which was developed by Eells and Elworthy and Malliavin.

1. Introduction

In the series of papers [23–25], Lyons introduced and began the development of the theory of rough paths on a Banach space \( W \). This theory allows us to model the evolution of interacting systems, driven by highly irregular non-differentiable inputs, modelled as differential equations driven by a rough path \( X \). The theory of rough paths provides existence and uniqueness of solutions to such equations; moreover, the solutions depend continuously on the driver \( X \). Among the many applications arising from the interplay of rough paths and stochastic analysis are the study of solutions to stochastic differential equations driven by Gaussian signals; see, for example, [2–4, 6, 15] and the analysis of broad classes of stochastic partial differential equations (PDEs) \([1, 8, 19, 20]\). Rough paths also provide us with alternative ways to think about and encode the information presented in a dynamical system.
A rough path of order $p \in [2, 3]$ on $[0, T]$ with values in a Banach space $(W, |\cdot|)$ is a pair of functions

$$X_{s,t} := (x_{s,t}, X_{s,t}) \in W \oplus W \otimes W,$$

which may be thought of as the increments of the path itself and a second-order term $X_{s,t}$. Rough paths are characterised by an algebraic property analogous to the homomorphism property of the Chen series of a path (also known as the multiplicative property) and an analytic $p$-variation type constraint on $X$. A great variety of stochastic classical processes may be lifted to rough paths. For example, every $\mathbb{R}^d$-valued continuous semi-martingale $(x_s)_{0 \leq s \leq T}$ (for example, Brownian motion) and large classes of Gaussian processes including fractional Brownian motion (fBM) with Hurst parameter $H > 1/4$ may almost surely be augmented by a process $X_{s,t}$. For continuous semi-martingales, for example, one may define

$$X_{s,t} := \int_{s \leq \tau \leq t} x_{s,\tau} \otimes dx_{\tau},$$

where the integral can either be interpreted as an Itô integral or a Fisk–Stratonovich integral. The resulting $X_{s,t}$ typically does depend on which integral is used.

In view of the fact that many (if not most) natural dynamical systems come with geometric constraints, it is natural and necessary to develop a theory of constrained rough paths, that is, rough paths on a manifold, $M$. There is some literature in this direction (see, for example, [17, 26, 27]) in which rough paths theory is used to define certain stochastic evolutions on a manifold. Nevertheless, these papers sidestep the issue of actually defining the notion of a rough path in a manifold. The analogue of the approach of these papers in the smooth category would be to proceed as follows. First, consider $M^d$ as an embedded submanifold in $\mathbb{R}^N$ for some $N$ and then only consider curves $\sigma : [0, 1] \rightarrow M$ that satisfy a differential equation in the ambient space $(\mathbb{R}^N)$ of the form

$$\dot{\sigma}(t) = \sum_{i=1}^D V_i(\sigma(t)) \dot{z}_i(t), \quad (1.1)$$

where $z : [0,1] \rightarrow \mathbb{R}^D$ is a smooth curve, and $\{V_i\}_{i=1}^D$ are smooth vector fields on $\mathbb{R}^N$ such that $V_i(x) \in T_x M$ for all $x \in M$. As a consequence, only after one has figured out how to present $\sigma$ in the form of equation (1.1) is one allowed to talk about integration along a 1-form, parallel translation, unrolling, etc. For example, if $\alpha$ is a 1-form on $M$, then the approach above would define the path integral of a 1-form $\alpha$ along $\sigma$ by

$$\int_{\sigma} \alpha := \int_0^1 \sum_{i=1}^D \alpha(V_i(\sigma(t))) \dot{z}_i(t) \, dt. \quad (1.2)$$

Clearly, this is unsatisfactory. For example, we certainly would like to know the integral is independent of the chosen presentation of $\sigma$ in equation (1.1). Moreover, from a practical and computational point of view, carrying around all of this extra structure would at best be very cumbersome and at worst would be an obstruction to developing analysis on paths and loops into a manifold, which are so prevalent in the context of Riemannian geometry and geometric PDEs.

The paper [5] is the first (and until now the only) paper which develops a consistent theory of rough paths on a manifold by viewing them as a sort of non-linear current space. The theory developed in [5] has the advantage of being global and intrinsic, but it does require a rather stringent condition that the manifold be ‘Lip-$\gamma$’. In this paper, we will remove this assumption and at the same time provide a concrete realisation of the currents appearing in [5]. Moreover,
it is our goal to carefully develop the tools needed to make the calculus of rough paths on manifolds effective and practical for future applications.

In this paper, we suppose that $M^d$ is a $d$-dimensional smooth manifold which has been embedded into some Euclidean space $E = \mathbb{R}^N$. Our first order of business is to ‘identify’ those weakly geometric rough paths $X = \{(x_s, X_{st}) : 0 \leq s \leq t \leq T\} \subset E \oplus E \otimes E$ which are ‘constrained’ to lie in $M$. This point is a bit subtle as the ‘obvious’ definition that $x_s \in M$ and $X_{st} \in T_x M \otimes T_x M$ is not the correct notion. Indeed, the condition that $X_{st} \in T_x M \otimes T_x M$ is too strict and will essentially only hold for constant rough paths. The key starting point of this paper is Definition 3.15, which basically states that a weakly geometric rough path $X = (x_s, X_{st}) \in E \oplus E \otimes E$ is constrained to $M$ if and only if 1-forms on $M$ can consistently be integrated along $X$. It is then shown in Section 3 that this condition is equivalent to $X_{st}$ being ‘approximately’ in $T_x M \otimes T_x M$; see Corollary 3.32. A number of other equivalent characterisations of Definition 3.15 are also given in Section 3.

Our definition of a rough path is natural in that it is the maximal class that permits a consistent definition of rough integration and, though our proofs and definitions will sometimes depend on the embedding, we will however show that the choice of embedding is not important; see Corollaries 3.40, 3.41, and Definition 3.42. In fact, the theory is intrinsic to the manifolds; in a forthcoming paper we clarify the relations of intrinsic and embedded definitions of rough paths on manifolds.

In the flat finite-dimensional setting it is known that the notions of weakly geometric and geometric rough paths are essentially equivalent. On the other hand, in the manifold setting presented here, the analogous result is not a priori known, and must be proved, which is not done until Theorem 4.17. After this point it would be possible to replace some of our proofs with smooth approximation arguments. However, we choose to avoid doing so as these approximation arguments obscure the interesting second-order differential geometric identities which underlie the theory. We believe this is important as the smooth approximation arguments will not be available when, in the future, one goes to transfer these results to infinite-dimensional settings.

The paper is organised as follows. Section 2 is devoted to introducing fundamental definitions and some preliminary results in Banach space-valued rough path theory. Section 3, as described above, is where we define a rough path in an embedded manifold.

Section 4 is devoted to the notion rough differential equations (RDEs) on $M$. Theorem 4.2 shows that one may solve a RDE on $M$ by extending the vector fields defining the differential equation to the ambient space, and then applying the Euclidean rough path theory to the resulting dynamical system. The output is a weakly geometric rough path in $M$ which does not depend on any of the choices made in the extensions. Later in Theorem 4.5, we derive an equivalent intrinsic characterisation of these solutions.

Section 5 develops the notion of rough parallel translation along manifold-valued rough paths. Parallel translation along a rough path $X$ in $M$ is defined as a rough path $U$ in the orthogonal frame bundle $O(M)$ over $M$ which solves a prescribed RDE on $O(M)$ driven by $X$; see Definition 5.13. It is shown in Proposition 5.15 that the RDE defining $U$ does not explode and so $U$ exists on the full time interval, $[0, T]$. It is then shown in Theorems 5.16 and 5.17 that two natural classes of RDE’s on $O(M)$ give rise to an element $U \in WG_p(O(M))$ each of which is parallel translation along $X := \pi_*(U)$, where $\pi : O(M) \to M$ is the natural projection map on $O(M)$. Here $\pi_*(U)$ denotes the pushforward of $U$ by $\pi$; see Proposition 3.38.

In Section 6, we show in Corollary 6.12 that there is (similar to the smooth theory) a one-to-one correspondence between rough paths on the orthogonal frame bundle $O(M)$ to and rough paths on the Euclidean space $\mathbb{R}^d \times so(d)$. Furthermore, Theorem 6.18, and Corollary 6.19 show there are one-to-one correspondence between rough paths on $M$, ‘horizontal’ rough paths on $O(M)$ (see Definition 6.14), and rough paths on $\mathbb{R}^d$. These results are rough path versions of the stochastic rolling construction of Brownian motion on a manifold via the orthogonal frame bundle as first appeared in Eells and Elworthy [10] and then further developed in Elworthy.
and in Malliavin [30]. We expect that the results of this paper will help lay the foundation of future work that explores the properties of manifold-valued solutions to stochastic differential equations driven by Gaussian processes such as fBMs.

The paper is completed with two appendices. In Appendix A, we gather together some needed results of the Banach space-valued rough path theory, while Appendix B explains a few details on how to view $O(M)$ as an embedded submanifold which are needed in Section 6 of the paper.

2. Background rough path results

2.1. Basic notations

In this section, we introduce some basic notations for rough paths on Banach spaces. In addition, we gather some elementary preliminary results that will prove useful in the sequel. Some additional rough path theory results on Banach spaces needed in this paper may also be found in Appendix A. Throughout this section, $V$, $W$, and $U$ will denote real Banach spaces. For simplicity in this paper, we will typically assume that all Banach spaces are finite-dimensional. If $(V, |·|)$ is a Banach space, then we will abuse notation and write $|·|$ for one of the tenor norms on $V \otimes V$. Because $\dim V < \infty$, the choice of tensor norm on $V \otimes V$ is unimportant. For $X \in V \otimes V$, we denote its symmetric and anti-symmetric part to be $X_s$ and $X_a$, respectively. The following definition and (abuse of) notation will frequently be used in the sequel.

**Definition 2.1 (Truncated tensor algebra).** Let $T_2(V) := \mathbb{R} \oplus V \oplus V \otimes V$, which we make into an algebra by using the multiplication in the full tensor algebra and then disregarding any terms that appear in $V \otimes^3 V \otimes^4 \ldots$. In more detail, if $a, b \in \mathbb{R}$, $x, y \in V$, and $X, Y \in V \otimes V$, then

$$(a, x, X)(b, y, Y) := (ab, ay + bx, aY + x \otimes y + bX).$$

In the future, we will typically write $a + x + X$ for $(a, x, X)$.

**Notation 2.2.** If $B : V \times V \to W$ is a bilinear form with values in a vector space $W$, then, by the universal property of the tensor product, there is a unique linear map, $\hat{B} : V \otimes V \to W$ such that $B(a, b) = \hat{B}(a \otimes b)$ for all $a, b \in V$. Given $A \in V \otimes V$, it will be useful to abuse notation and abbreviate $\hat{B}(A)$ as $B(a, b)|_{a \otimes b = A}$. For example, if $A = \sum_{i=1}^{l} a_i \otimes b_i \in V \otimes V$, then it follows that

$$B(a, b)|_{a \otimes b = A} := \sum_{i=1}^{l} B(a_i, b_i).$$

Throughout this paper, we let $T$ denote a positive finite real number, $p$ be a fixed real number in the interval $[2, 3)$ and $\omega$ be a control whose definition we now recall.

**Definition 2.3.** A control $\omega : \Delta_{[0, T]} := \{(s, t) : 0 \leq s \leq t \leq T\} \to \mathbb{R}_+$ is a continuous non-negative function which is superadditive, positive off the diagonal, and zero on the diagonal in $\Delta_{[0, T]}$.

**Definition 2.4 (Rough paths).** For a Banach space $V$, the set of ($\omega$-controlled $V$-valued) $p$-rough paths consists of pairs $X = (x, X)$ of continuous paths

$$x : [0, T] \to V \quad \text{and} \quad X : \Delta_{[0, T]} \to V \otimes V,$$
satisfying the following conditions:

1. the Chen identity: that is,
   \[ X_{s,t} = X_{s,u} + X_{u,t} + X_{s,u} \otimes X_{u,t} \quad \forall 0 \leq s \leq u \leq t \leq T, \tag{2.1} \]

   where here, as throughout, \( x_{s,t} := x_t - x_s \) will denote the increment of the path \( x \) over \([s,t]\);

2. a \( p \)-variation regularity constraint:
   \[
   \sup_{0 \leq s < t \leq T} \frac{|x_{s,t}|}{\omega(s, t)^{1/p}} < \infty \quad \text{and} \quad \sup_{0 \leq s < t \leq T} \frac{|X_{s,t}|}{\omega(s, t)^{2/p}} < \infty. \tag{2.2}
   \]

In the following, we will refer to the path \( x \) also as the trace of the rough path. We can identify a rough path as a map taking values in the tensor algebra.

**Remark 2.5.** It is often convenient to identify a rough path, \( X = (x, X) \), with the function \( X : \Delta_{[0,T]} \to T_2(V) \) defined by

\[
X_{s,t} := 1 + x_{s,t} + X_{s,t}, \quad (s, t) \in \Delta_{[0,T]}. \]

Using this identification, Chen’s identity becomes the following multiplicative property of \( X \):

\[
X_{s,t} = X_{s,u}X_{u,t} \quad \forall 0 \leq s \leq u \leq t \leq T, \tag{2.3}
\]

where multiplication is given as in Definition 2.1.

The collection of \( V \)-valued \( p \)-rough paths controlled by \( \omega \) is denoted by \( R_p([0,T], V, \omega) \) (also denoted by \( R_p(V) \) where no confusion arises).

**Example 2.6.** Suppose \( x : [0,T] \to V \) is a continuous bounded variation path. Then a simple example of a \( p \)-rough path is the (truncated) signature \((S_2(x))_{s,t} := X_{s,t} \mid 0 \leq s < t \leq T \)

defined by

\[
X_{s,t} := 1 + x_{s,t} + X_{s,t} \in T_2(V), \tag{2.4}
\]

where

\[
X_{s,t} := \int_{s < t_1 < t_2 < t} dx_{t_1} \otimes dx_{t_2} = \int_s^t x_{s,u} \otimes dx_u \tag{2.5}
\]

and the latter integral being the Lebesgue–Stieltjes integral. For the control, we may take

\[
\omega(s, t) = |x|_{1\text{-var};[s,t]} := \sup_{D = \{t_1, \ldots, t_n \}} \sum_{i=1}^n |x_{t_{i-1}, t_i}|.
\]

In this case, \( X \) is not an extra piece of information but is in fact determined by the basic path \( x \).

**Remark 2.7.** If \( x : [0,T] \to V \) is continuous and of bounded variation and \( X \) is given as in equation (2.5), then as a consequence of the fundamental theorem of calculus the symmetric part of \( X_{st} \) satisfies

\[
X_{st}^* = \frac{1}{2} x_{s,t} \otimes x_{s,t} \quad \forall 0 \leq s \leq t \leq T. \tag{2.6}
\]

In this paper, we are interested in the following two important subsets of \( R_p(V) \).
Definition 2.8 ($WG_p(V)$ and $G_p(V)$). Let $X$ be a $V$-valued $p$-rough path, that is, $X \in R_p(V)$.

1. We say that $X$ is a geometric $p$-rough path, and write $X \in G_p(V)$ if $X$ belongs to the closure of the set

$$\{Y : Y = S_2(y), \ y \text{ continuous and of finite } 1\text{-variation} \}$$

with respect to the topology induced by the metric (A.1).

2. We say that $X$ is a weakly geometric $p$-rough path, and write $X \in W G_p(V)$ if equation (2.6) holds.

Remark 2.9. If dim$(V) < \infty$ and $p < q$, then we have the strict inclusions $G_p(V) \subset W G_p(V) \subset G_q(V)$ (see [16, Corollary 8.24]) and so one typically does not have to pay much attention to the difference between geometric and weakly geometric rough paths. However, in infinite dimensions the compactness argument used in the proof that $W G_p(V) \subset G_q(V)$ breaks down.

2.2. Approximate rough paths and integration

The following notation will be used heavily in this paper.

Notation 2.10 ($\simeq$ and $\sim_{\delta}$). Let $\omega$ be a control, and assume that $g$ and $h$ are continuous functions from $\Delta_{[0,T]}$ into some Banach space $W$. Then we will write

$$g_{s,t} \simeq h_{s,t}$$

if there exists $\delta > 0$ and a constant $C(\delta) > 0$ such that, for all $s$ and $t$ in $[0,T]$ satisfying $|s-t| \leq \delta$, then we have

$$|g_{s,t} - h_{s,t}| \leq C(\delta)\omega(s,t)^{3/p}.$$

If we wish to emphasize the dependence on $\delta$, then we will write $g_{s,t} \sim_{\delta} h_{s,t}$.

Remark 2.11. As a typical application of this notation, let us note that if $g : [0,T] \to V$ is continuous and such that $g_{s,t} \simeq 0$, then, because the increments form an additive function on $\Delta_{[0,T]}$, it must be that $g$ is constant. Indeed, if $D = \{t_i : k = 0, 1, \ldots, n\}$ is any partition of $[0, t] \subset [0, T]$ with $|D| \leq \delta$, then

$$|g_{0,t}| = \sum_{i=1}^{n} |g_{t_i, t_{i+1}}| \leq \sum_{i=1}^{n} |g_{t_i, t_{i+1}}| \leq C(\delta)|D|^{3/p-1}\omega(0,t)$$

which tends to 0 as $|D| \to 0$.

This elementary remark may be strengthened to apply to rough paths. The difficulty of course that the second (and higher) order processes are no longer additive with respect to $(s, t)$. The following lemma is due to Lyons [25], and is used to powerful effect in his Extension Theorem.

Lemma 2.12. Suppose $(x, X)$, $(y, Y) \in R_p(V)$ satisfy $a_{s,t} := x_{s,t} - y_{s,t} \simeq 0$ and $a_{s,t} := X_{s,t} - Y_{s,t} \simeq 0$. Then the two rough paths coincide, that is, $(x, X) = (y, Y)$. In particular, this taking $(y, Y)$ to be the zero rough path in $R_p(V)$, we may conclude that if $(x, X) \in R_p(V)$ satisfies $x_{s,t} \simeq 0$ and $X_{s,t} \simeq 0$, then $x_{s,t} = 0$ and $X_{s,t} = 0$ for all $0 \leq s \leq t \leq T$. 

Proof. Since $a_{s,t}$ is additive, we must have, for every partition $D$ of $[s,t]$, 
\[
|a_{s,t}| = \left| \sum_{i:t_i \in D} a_{t_i,t_{i+1}} \right| \longrightarrow 0 \quad \text{as } |D| \longrightarrow 0,
\]
and hence $x_{s,t} = y_{s,t}$. It follows from [29, Lemma 3.4] that $A_{s,t}$ is also additive and repeating
the argument with $A_{s,t}$ in place of $a_{s,t}$ yields the claim.

We say a functional $Z := (z, Z)$ defined by 
\[
Z_{s,t} := 1 + z_{s,t} + Z_{s,t} \in T_2(V) \quad \forall \ (s,t) \in \Delta_{[0,T]}
\]
is an almost rough path if it satisfies the requirements of Definition 2.4 except identity (2.1), but instead
\[
Z_{s,u} - Z_{s,t} - Z_{t,u} - z_{s,t} \otimes z_{t,u} \simeq 0,
\]
holds, that is, it approximately satisfies the multiplicative identity (2.1). The following theorem
due to Lyons is a cornerstone for the development of the integration for rough paths. It states
that, for every almost rough path, there exists a unique rough path that is ‘close.’ Note that
the uniqueness follows from Lemma 2.12.

Theorem 2.13. Let $Z := (z, Z)$ be an almost rough path on $V$. Then there exists a unique
rough path $X = (x, X) \in R_p(V)$ such that $x_{s,t} \simeq z_{s,t}$ and $Z_{s,t} \simeq X_{s,t}$.

The following result due to Lyons [25] allows us to define the integral of a rough path against
a sufficiently regular 1-form.

Theorem 2.14. Suppose that $Z \in WG_p(V)$ and $\alpha \in C^2(V, \text{End}(V,W))$ is a 1-form on $V$ with values in $W$. Then there is a unique $X \in WG_p(W)$ such that $x_0 = 0$, 
\[
X_{s,t} \simeq \alpha(z_s)Z_{s,t}^1 + \alpha'(z_s)Z_{s,t}, \quad (2.7)
\]
and 
\[
X_{s,t} \simeq \alpha(z_s) \otimes \alpha(z_s)Z_{s,t}. \quad (2.8)
\]

In the future, we will denote this $X$ by $\int \alpha(dZ)$ and use it as the definition for the rough
integral. The proof is a consequence of Theorem 2.13. The rough path integral has a number
of important properties, in particular the map taking 
\[
Z \longrightarrow \int \alpha(dZ)
\]
is continuous in the rough path metric (A.1).

2.3. Rough differential equations

The following definition of a RDE is in the spirit of Davie [7] and may be found, for example,
in Friz and Hairer [14, Proposition 8.4].

Definition 2.15 (RDE). Let $Z \in WG_p(W)$ and $Y : V \rightarrow \text{Hom}(W, V)$ be a $C^1$-map. Then
$X \in WG_p(E)$ solves the RDE 
\[
dX = Y(x)dz
\]
(2.9)
if and only if
\[ x_{s,t} \simeq Y(x_s)z_{s,t} + Y'(x_s)Y(x_s)Z_{s,t}, \]
\[ X_{s,t} \simeq [Y(x_s) \otimes Y(x_s)]Z_{s,t}, \]
where
\[ Y'(x_s)Y(x_s)[a \otimes b] := (Y'(x_s)Y(x_s)a)b = (∂Y'(x_s)aY)(x_s)b. \]
Alternatively, if we let \( Y_δ(x) := Y(x)b, \) then
\[ Y'(x_s)Y(x_s)[a \otimes b] := Y_δ'(x_s)Y_δ(x_s) = (∂Y_δ'(x_s)Y_δ)(x_s). \]

Existence and uniqueness of solutions for RDEs defined by sufficiently regular vector fields is due to Lyons [25]. The following theorem is an easy consequence of [16, Theorem 10.14].

**Theorem 2.16 (RDE existence and uniqueness).** Let \( p \in [2,3), \mathbf{Z} \in WG_p(W, [0, T]), Y : V \to \text{Hom}(W, V) \) be a smooth map and, for \( k \in \{0,1,2,\ldots\}, \) let
\[ M_Y := \max\{\|Y\|_∞, \|Y'\|_∞, \|Y''\|_∞\} < ∞, \] (2.10)
then there exists a unique \( \mathbf{X} \in WG_p(V, [0, T]) \) that solves the RDE (2.9) over \([0, T]\) in the sense of Definition 2.15. In addition, there exists a constant \( C_p \) (depending only on \( p \)) such that
\[ \|x\|_{p-\text{var}[u,v]} \leq C_p \max\{M[Y]\|Z\|_{p-\text{var}[u,v]}, M^p[Y]\|Z\|_{p-\text{var}[u,v]}^p\} \forall 0 \leq u < v \leq T. \] (2.11)

The following corollary is a localisation of Theorem 2.16 which will prove useful later.

**Corollary 2.17 (Local RDE existence).** Let \( U \subset V \) be an open neighbourhood, \( U_1 \) be a precompact open neighbourhood with closure in \( U \) and \( Y : U \to \text{Hom}(W, V) \) be a smooth map. Then there exists \( δ > 0 \) such that, for all \((x, t_0) \in U_1 \times [0, T], \)
\[ d\mathbf{X} = Y(x) d\mathbf{Z}, \quad x_{t_0} = x \] (2.12)
has a unique solution \( \mathbf{X} \in WG_p(V, [t_0, t_0 + δ \wedge T]) \) in the sense of Definition 2.15 (naturally with trace \( x_t \in U \) for all \( t \in [t_0, t_0 + δ \wedge T] \)).

**Proof.** Choose another open precompact subset, \( U_2, \) of \( V \) so that \( \bar{U}_1 \subset U_2 \subset \bar{U}_2 \subset U \) and choose \( φ \in C^∞_c(U) \) such that \( φ = 1 \) on \( \bar{U}_2 \). Let \( \bar{Y} = φY \) which we then extend to be zero outside of \( U. \) Clearly, \( M_φ < ∞, \) where \( M_φ \) is as in equation (2.10) with \( Y \) replaced by \( \bar{Y} \).

Recall that if \( u(s, t) := \|Z\|_{p-\text{var}[u,v]} \) for \((s, t) \in Δ_{0,T},\) then \( u^p(s, t) \) is a control and, in particular, \( u(s, t) \) is continuous on \( Δ_{0,T} \) and vanishes on the diagonal. Therefore, if \( ε := \text{dist}(U_1, U_2) > 0, \) then there exists (by the uniform continuity of \( u \)) a \( δ > 0 \) such that
\[ C_p \max\{M_φ[Y]\|Z\|_{p-\text{var}[t_0, t_0 + δ \wedge T]}, M^p_φ[Y]\|Z\|_{p-\text{var}[t_0, t_0 + δ \wedge T]}^p\} < ε \quad ∀ t_0 \in [0, T]. \]
By Theorem 2.16, given any \((x, t_0) \in U_1 \times [0, T],\) there exists a unique \( \mathbf{X} \in WG_p(V, [t_0, T]) \) that solves
\[ d\mathbf{X} = \bar{Y}(x) d\mathbf{Z}, \quad x_{t_0} = x. \] (2.13)
By the choice of \( δ, \) the bound in equation (2.11), and the triangle inequality, it follows that \( x_t \in U_2 \subset U \) for all \( t \in [t_0, t_0 + δ \wedge T]. \) As \( Y = \bar{Y} \) on \( U_2, \) it follows that \( \mathbf{X} \) also solves (2.12) on \([t_0, t_0 + δ \wedge T].\) \( \Box \)
The solutions of rough differential equations satisfy a universal limit theorem which states that the map taking \(X\) to the solution \(Z\) is continuous in the \(p\)-variation metric on rough paths (see [25]). We also remark that the original definition of the solution of a rough differential equation (see Lyons [25]) is given in terms of a fixed point of a rough integral on \(V \oplus W\).

Lemma 2.18 implies that, for sufficiently regular vector fields, an RDE solution blows up if and only if both the trace and the second-order process of the solution explode. In other words, it is not possible for the explosion of a solution of an RDE to be caused only by the explosion of the second-order process of the solution.

**Lemma 2.18 (Augmentations for free).** Let \(Z \in WG_p(W)\) and \(Y : V \to Hom(W, V)\) be a smooth map and consider the RDE

\[
dX = Y(x) dZ \quad \text{with} \quad x(0) = x_0,
\]

where \(x_0\) is given. Suppose that we can solve this equation for the trace part, that is,

\[
x_{s,t} \simeq Y(x_s) z_{s,t} + Y'(x_s) Y(x_s) Z_{s,t}
\]

holds for \(0 \leq s, t \leq T\). Then there exists a lift \(X \in WG_p(V)\) of \(x\) that solves (2.14) over \([0, T]\).

**Proof.** We can augment the trace solution \(x\) to a full rough path solution \(X := (x, \mathcal{X})\) as follows. Let

\[
\mathcal{A}_{s,t} := [Y(x_s) \otimes Y(x_s)] Z_{s,t} \quad \text{and} \quad \mathcal{A}_{s,t} := 1 + x_{s,t} + \mathcal{A}_{s,t}.
\]

Note that \(Y\) is bounded on \(x\) and therefore \(\mathcal{A}\) has finite \(p\)-variation in the sense of (2.2). It now suffices to check that \(\mathcal{A}\) is an almost multiplicative functional in the language of Lyons. For this, it will be enough to check that \(\mathcal{A}\) approximately (in the sense of Notation 2.10) satisfies Chen’s identity, which we now do. If \(0 \leq s \leq t \leq u \leq T\), then

\[
\mathcal{A}_{s,u} = [Y(x_s) \otimes Y(x_t)] Z_{s,u} \simeq [Y(x_s) \otimes Y(x_s)] Z_{s,u}
\]

so that

\[
\mathcal{A}_{s,u} - \mathcal{A}_{s,t} - \mathcal{A}_{t,u} \simeq [Y(x_s) \otimes Y(x_s)] [Z_{s,u} - Z_{s,t} - Z_{t,u}]
= [Y(x_s) \otimes Y(x_s)] [z_{s,t} \otimes z_{t,u}].
\]

Similarly, we have

\[
x_{s,t} \otimes x_{t,u} \simeq Y(x_s) z_{s,t} \otimes Y(x_t) z_{t,u} \simeq Y(x_s) z_{s,t} \otimes Y(x_s) z_{t,u},
\]

which combined with equation (2.16) shows

\[
\mathcal{A}_{s,u} - \mathcal{A}_{s,t} - \mathcal{A}_{t,u} - x_{s,t} \otimes x_{t,u} \simeq 0
\]

which is to say that \(\mathcal{A}_{s,t}\) is an almost multiplicative functional. Thus by Theorem 2.13 there exists \(\mathcal{X}_{s,t}\) such that \(\mathcal{X}_{s,t} \simeq \mathcal{A}_{s,t}\) and \(X_{s,t} = 1 + x_{s,t} + \mathcal{X}_{s,t}\) solves the RDE in equation (2.14).

\[\square\]

3. **Geometric and weakly geometric rough paths on manifolds**

In this section, we will introduce the notions of geometric and weakly geometric rough paths on manifolds. The section is split in four parts. Subsection 3.1 introduces the basic geometric notations and facts needed for the rest of the paper. The definitions of constrained rough paths (now called geometric and weakly geometric rough paths) and their path integrals
are introduced in Subsection 3.2; see Definitions 3.15, 3.17, and 3.24. Basic properties of these definitions are then established. The main result of Subsection 3.3, is Proposition 3.35, which gives a more effective criterion for checking that an ambient rough path is in fact a weakly geometric rough path. The final Subsection 3.4 explores the behaviour of constrained rough paths under change of coordinates and more general smooth transformations; see Proposition 3.38. This result is then used to demonstrate that our constrained rough paths may be formulated to be independent of the choice of embedding; see Corollaries 3.40, 3.41, and Definition 3.42.

3.1. Basic geometric definitions

Let $E = \mathbb{R}^N$ and $E' = \mathbb{R}^{N'}$ be Euclidean spaces and let $\langle a, b \rangle = a \cdot b = \sum_{i=1}^{N} a_i b_i$ for all $a, b \in E$. If $U$ is an open neighbourhood in $E$ and $F : U \to E'$ is a smooth map, then, for $x \in U$ and $v \in E$, we let $\partial_v F(x) := d/dt|_0 F(x + tv)$ be the directional derivative of $F$ at $x$ along $v$. We will further let $F'(x) : E \to E'$ and $F''(x) : E \otimes E \to V := \mathbb{R}^{N-d}$ be the differential and Hessian of $F$, respectively, which are defined by $F'(x)v := (\partial_v F)(x)$ and $F''(x)[v \otimes w] := (\partial_v \partial_w F)(x)$ for all $x \in U$ and $v, w \in E$.

Throughout the rest of this paper, $M^d$ will be a $d$-dimensional embedded submanifold of a Euclidean space $E := \mathbb{R}^N$. The reader may find the necessary geometric background in any number of places including [9, 21, 31]. To fix notation let us recall a formulation an embedded submanifold which will be most useful for our purposes.

**Definition 3.1.** A subset $M$ of $E$ is an embedded submanifold of $E$ of dimension $d \in \{1, \ldots, N\}$, provided for each $m \in M$ there is an open neighbourhood $U$ in $E$ containing $m$ and smooth local defining function $F : U \to \mathbb{R}^{N-d}$ such that

$$U \cap M = \{ x \in U : F(x) = 0 \}$$

and $F'(x) : E \to \mathbb{R}^{N-d}$ is surjective for $x \in U$.

Recall that the tangent plane to $M$ at $m \in M$ is $\tau_m M := \text{Nul}(F'(m))$. Because of the implicit function theorem, to each $v \in \tau_m M$ there exists a smooth path $\sigma_v : (-\varepsilon, \varepsilon) \to E$ such that $\sigma_v((-\varepsilon, \varepsilon)) \subset M$, $\sigma_v(0) = m$, and $\sigma'_v(0) = v$. From these considerations, one shows $\tau_m M \ni v \to \sigma_v(0) \in T_m M$ is a linear isomorphism of vector spaces; we will often use this isomorphism to identify $\tau_m M$ with $T_m M$.

**Remark 3.2.** Around each point $m \in M$ there exists an open set $U$ in $E$ and a smooth map $\pi : U \to M \cap U$ such that $\pi(x) = x$ for all $x \in M \cap U$. As a consequence of this fact, any smooth function $f : M \to W$ defined near $m$ has a smooth extension, $f \circ \pi$, to a neighbourhood of $m$ in $E$.

**Notation 3.3.** Letting $F : U \to \mathbb{R}^{N-d}$ be a local defining function for $M$ as above, we define smooth functions $Q_F, P_F : U \to \text{End}(E)$ by

$$Q_F(x) := F'(x)^*(F'(x)F'(x)^*)^{-1}F'(x) \quad \text{and} \quad P_F(x) := I_E - Q_F(x) = I - F'(x)^*(F'(x)F'(x)^*)^{-1}F'(x).$$

(3.1) \quad (3.2)

**Remark 3.4.** We make a number of comments.

1. The surjectivity assumption of $F'(x)$ guarantees that $F'(x)F'(x)^*$ is invertible.
2. One may easily verify that $Q_F(x)$ is orthogonal projection onto $\text{Ran}(F'(x)^*) = \text{Nul}(F'(x))^\perp$ and $P_F(x)$ is orthogonal projection onto $\text{Nul}(F'(x))$. 
For $m \in U \cap M$, we have that $P_F(m)(Q_F(m))$ is the orthogonal projection onto $\tau_m M (\tau_m M)^\perp$ and hence is independent of the choice of local defining function. We will simply write $P(m)$ and $Q(m)$ (or, sometimes, $P_m$ and $Q_m$) for $P_F(m)$ and $Q_F(m)$ when $m \in M$.

**Remark 3.5.** In the proofs that follow we will often use the following identities:

$$F'(x) = F'(x)Q_F(x) \quad \text{and} \quad Q_F(x) = A_F(x)F'(x)$$  \hspace{1cm} (3.3)

which hold for all $x \in M$, where

$$A_F(x) := (F'(x))^*(F'(x)F'(x))^*)^{-1} \in \text{Hom}(\mathbb{R}^{N-d}, E).$$  \hspace{1cm} (3.4)

The last geometric notions we need are vector fields, 1-forms and their covariant derivatives.

**Definition 3.6 (Vector fields).** A smooth vector field on $M$ is a smooth function $Y : M \to E$ such that $Q(m)Y(m) = 0$ for all $m \in M$, that is $Y(m) \in T_m M$ for all $m \in M$. Let $\Gamma(TM)$ denote the collection of smooth vector fields on $M$.

**Example 3.7.** For $z \in \mathbb{R}^N$, we let $V_z \in \Gamma(TM)$ be defined by $V_z(x) := P_z z$ for all $x \in M$.

**Definition 3.8.** A smooth 1-form on $M$ with values in a finite-dimensional vector space $W$ is a smooth function $\alpha$ on $M$ with $\alpha_m \in \text{Hom}(T_m M, W)$ for all $m \in M$. Here we can describe the smoothness assumption of $\alpha$ by requiring $M \to E \to W$ for all $m \in M$. Let $\Omega^1(M, W)$ denote the set of smooth 1-forms on $M$ with values in $W$.

**Example 3.9.** The function $\alpha_m := P_m$ is in $\Omega^1(M, E)$. If $f : M \to W$ is a smooth function, then $\alpha := df \in \Omega^1(M, W)$ where as usual $df(m) = v_m f$.

**Definition 3.10 (Levi-Civita covariant derivative).** Suppose that $v_m \in T_m M$, $Y \in \Gamma(TM)$, and $\alpha \in \Omega^1(M, W)$; then the covariant derivative at $v_m$ of $Y$ and $\alpha$ are given, respectively, by

$$\nabla_{v_m} Y = P_m(\partial_{v_m} Y)(m) \in T_m M \quad \text{and} \quad \nabla_{v_m} \alpha = \partial_{v_m}(\alpha \circ P) \in \text{Hom}(T_m M, W).$$

The next lemma and proposition records some basic well-known properties of the Levi-Civita covariant derivative.

**Lemma 3.11.** If $P$ and $Q$ be the orthogonal projection operators as in Remark 3.4, then $dP = -dQ$ and $PdQ = dQP$.

**Proof.** Differentiate the identities $I = P + Q$ and $0 = PQ$, which hold on $M$ giving the new identities in the statement. $\square$

**Proposition 3.12.** Let $Y \in \Gamma(TM)$, $\alpha \in \Omega^1(M, W)$, and $\Gamma := dQ \in \Omega^1(M, \text{End}(E))$. Then the following conditions are satisfied.

1. $\nabla_{v_m} Y = (\partial_{v_m} Y)(m) + \Gamma(v_m) Y(m)$.
2. The product rule holds:

$$v_m(\alpha(Y)) = (\nabla_{v_m} \alpha)(Y(m)) + \alpha_m(\nabla_{v_m} Y).$$

3. If $\alpha_m = \tilde{\alpha}_m|_{T_m M}$, where $\tilde{\alpha} : M \to \text{Hom}(E, W)$ is a smooth function, then

$$\nabla_{v_m} \alpha = (\partial_{v_m} \tilde{\alpha})(m)P_m - \tilde{\alpha}_m \Gamma(v_m).$$
If $\alpha_m = \tilde{\alpha}_m|_{T_mM}$ as in item 3 and we further assume that $\tilde{\alpha}_x = \tilde{\alpha}_x \circ P_x$ for $x \in M$ near $m$, then

$$(\nabla_v \alpha)(w) = \tilde{\alpha}_m'[v \otimes w] \text{ for all } v, w \in T_mM.$$  

Proof. In the proof below recall that $Y = PY$ as $Y \in \Gamma(TM)$.

1. Differentiating the identity, $Y = PY$, shows

$$(\partial_v Y)(m) = dP(v_m)Y(m) + P(m)(\partial_v Y)(m) = -\Gamma(v_m)Y(m) + \nabla v_m Y,$$

which proves item 1.

2. Since $\alpha(Y) = \alpha(\alpha(P)Y)$ and $\alpha P : M \to \text{End}(E)$ is a smooth function, the ordinary product rule shows

$$v_m(\alpha(Y)) = (\partial_v (\alpha P)(m))Y(m) + \alpha_{m}P_m(\partial_v Y)(m)$$

$$= (\nabla v_m \alpha)(Y(m)) + \alpha_{m} \nabla v_m Y.$$  

3. If $\alpha_m = \tilde{\alpha}_m|_{T_mM}$ as in item 3, then using the standard product rule again,

$$\nabla v_m \alpha = \partial_v (\alpha P)(m) = \partial_v (\tilde{\alpha} P)(m) = (\partial_v \tilde{\alpha}) P_m + \tilde{\alpha}_m dP(v_m) = (\partial_v \tilde{\alpha})(m)P_m - \tilde{\alpha}_m \Gamma(v_m).$$

4. From the definitions

$$(\nabla_v \alpha)(w) = [v_m(\alpha \circ P)]w = [v_m(\tilde{\alpha} \circ P)]w = [v_m \tilde{\alpha}]w = \tilde{\alpha}_m'(v \otimes w).$$  

3.2. (Weakly) geometric rough paths on $M$

In the following, let $M$ be a manifold embedded in $E := \mathbb{R}^N$ and $F$ be the (local) defining function as introduced in Notation 3.3. In the setting of embedded manifolds there is a natural notion of geometric rough paths that is induced by the rough metric on the ambient Euclidean space $E$. To help prepare the precise definition of a geometric rough path on a manifold, we introduce the following set of paths.

Assume that $M \subseteq E$ and let $C_{bv}([0, T], E)$ denote the set of continuous bounded variation paths taking values in $E$. Recall the definition of the truncated signature $S_2$ in (2.4). For any real number $p \in [2, 3)$, we define $\tilde{G}_p(M)$ to be closure of the lifts of continuous bounded variation paths in $M$; that is, $\tilde{G}_p(M)$ is the closure of

$$\{S_2(x) : x \in C_{bv}([0, T], E), x_t \in M \text{ for all } t \in [0, T]\}$$

with respect to the topology induced by the $p$-variation rough path metric on $E$.

Remark 3.13. For $p > 1$ continuous bounded variation paths on $E$ are in the closure of the smooth paths taken in the $p$-variation metric (see, for example, [16, Lemma 5.30]). In addition, the truncated signature is a locally Lipschitz continuous map under the (inhomogeneous) rough $p$-variation metric (see, for example, [16, Theorem 9.10]). Combining these two facts shows we could have replaced $C_{bv}([0, T], E)$ in the definition of $\tilde{G}_p(M)$ by the smooth paths $C^\infty([0, T], E)$. This justifies referring to the lifts of $1$-rough paths as ‘smooth’ rough paths.

Lemma 3.14. Suppose that $M$ is a closed subset of $E$; then the trace $x$ of any $X = (x, \Xi)$ in $\tilde{G}_p(M)$ lies in $M$.

Proof. By definition $X$ can be approximated by a sequence of smooth rough paths $X^n$ (see Remark 3.13) with trace in $M$. The traces of the approximating sequence converges in $p$-variation and therefore also converges pointwise. Since $M$ is assumed to be closed, the proof is complete.
Definition 3.15 (Geometric rough paths). We define geometric $p$-rough paths on $M$ to be those elements of $G_p(M)$ whose trace $x$ lies inside $M$. The set of geometric $p$-rough paths on $M$ will be denoted by $G_p(M)$. In other words, we have

$$G_p(M) = \{ X=(x, X) \in G_p(M) : x_t \in M \text{ for all } t \in [0, T] \}.$$ 

It follows from Lemma 3.14 that $\bar{G}_p(M) = G_p(M)$ when $M$ is a closed subset of $E$. The next example explains why it is important that we take the closure of paths in $M$, and why it will not be sufficient to only assume that the trace of limiting object lies in $M$.

Example 3.16. Let $M = \{e_1, e_2\}^1 \subset \mathbb{R}^N$. Then, for any $v, w \in \mathbb{R}^N$, there exists (see [14, 29]) a so-called pure area geometric rough path, $X=(x, X)$, with the property that $x = 0$, the constant path zero, and

$$X_{s,t} = (v \otimes w - w \otimes v)(t-s).$$

On the other hand, if $X \in WG_p(M)$, then we would certainly have $X_{s,t} \in M \otimes M$ for all $s$ and $t$. Put another way, if $X \in WG_p(M)$, then $[Q \otimes I]X_{s,t} = 0 = [I \otimes Q]X_{s,t}$, where $Q$ is orthogonal projection onto $M^\perp = \operatorname{span}\{e_1, e_2\}$. An approximate version of this requirement will appear again in the general manifold setting as well; see Corollary 3.20.

A second set of rough paths on a manifold is, in structure, related to the weakly geometric rough paths in the classical Banach space setting.

Definition 3.17 (Weakly geometric rough paths). We say that $X=(x, X)$ is a weakly geometric $p$-rough path on the manifold $M$ if: $X$ is in $WG_p(E)$, its trace $x$ lies in $M$ and, for any finite-dimensional subspace $W$ and any $\tilde{\alpha} \in \Omega^1(E,W)$ such that $\tilde{\alpha}|_{TM} \equiv 0$, we have $\int \tilde{\alpha}(dX) \equiv 0$. The set of weakly geometric rough paths will be denoted by $WG_p(M)$.

In the following, we will often make use of the following simple consequence of Taylor’s theorem.

Lemma 3.18. If $f : E := \mathbb{R}^N \to \mathbb{R}^l$ is a $C^3$-function which is constant on $M \subset E$, then, for $x, y \in M$, we have

1. $f'(x)(y-x) = O(|y-x|^2)$, and
2. $f'(x)(y-x) + \frac{1}{2} f''(x)[(y-x) \otimes (y-x)] = O(|y-x|^3)$.

Proof. By Taylor’s theorem,

$$f(y) - f(x) = f'(x)(y-x) + O(|y-x|^2)$$

and

$$f(y) - f(x) = f'(x)(y-x) + \frac{1}{2} f''(x)[(y-x) \otimes (y-x)] + O(|y-x|^3).$$

Since $f$ is constant on $M$ and $x, y \in M$, it follows that $f(y) - f(x) = 0$ and the results follow from the previously displayed equations.

An obvious class of 1-forms having the property that $\tilde{\alpha}|_{TM} \equiv 0$ are those which locally have the form $\alpha = \varphi F'$, where $\varphi$ is a smooth function and $F$ is a local defining function for the manifold. The following lemma gives simplified description of the level one component for the integral of any such 1-form.
Then \( \alpha \in \Omega^1(E, W) \) be the 1-form defined by
\[
\alpha(x) \xi = \varphi(x) F'(x) \xi \in W \quad \text{for all } \xi \in E.
\]
Then, for every \([u, v] \subseteq [s, t]\), we have
\[
\left[ \int \alpha(dX) \right]_{u,v}^1 \simeq \alpha(x_u) x_{u,v} + \alpha'(x_u) X_{u,v} \simeq [(\varphi' \cdot F')(x_u)] X_{u,v},
\]
where \((\varphi' \cdot F')(m)\) denotes the linear map from \(E \otimes E \to W\) determined by
\[
[(\varphi' \cdot F')(m)] \xi_1 \otimes \xi_2 := [\varphi'(m) \xi_1] [F'(m) \xi_2] = (\partial_{\xi_1} \varphi(m) (\partial_{\xi_2} F)(m).
\]

**Proof.** The product rule (written in the notation introduced in equation (3.6)) gives
\[
\alpha' = \varphi F'' + \varphi' \cdot F'.
\]
This identity combined with equation (2.7) then implies
\[
\int \alpha(dX)(X_{u,v}) \simeq \alpha(x_u) x_{u,v} + \alpha'(x_u) X_{u,v}
\]
\[
= \varphi(x_u) F'(x_u) x_{u,v} + \varphi'(x_u) F''(x_u) x_{u,v} + \varphi' \cdot F'(x_u) X_{u,v}
\]
\[
= \varphi(x_u) F'(x_u) x_{u,v} + F''(x_u) X_{u,v} \simeq ((\varphi' \cdot F') x_u) X_{u,v}.
\]
Since \( F'' \) is symmetric and \( X = (x, \xi) \) is a weakly geometric rough path, it follows that
\[
F''(x_u) X_{u,v} = F''(x_u) X'_{u,v} = \frac{1}{2} F''(x_u) [x_{u,v} \otimes x_{u,v}]
\]
and, therefore, by Lemma 3.18,
\[
F'(x_u) x_{u,v} + F''(x_u) X_{u,v} = F'(x_u) x_{u,v} + \frac{1}{2} F''(x_u) [x_{u,v} \otimes x_{u,v}] \simeq 0.
\]
Combining this estimate with equation (3.8) gives (3.5).

**Corollary 3.20.** Let \( X = (x, \xi) \in \text{WG}_p(M) \subseteq \text{WG}_p(E) \) and \( F : U \to V := \mathbb{R}^{N-d} \) and \([s, t] \subseteq [0, T]\) be as in Lemma 3.19. Then, for \( s \leq u \leq v \leq t\),
\[
I_E \otimes F'(x_u) X_{u,v} \simeq 0 \simeq F'(x_u) \otimes I_E X_{u,v} \quad \text{and}
\]
\[
I_E \otimes Q(x_u) X_{u,v} \simeq 0 \simeq Q(x_u) \otimes I_E X_{u,v},
\]
where \( Q \) is defined in Notation 3.3 and Remark 3.4.

**Proof.** Choose \( \varphi \in C^\infty_c(U, E) \) such that \( \varphi(x) = x \) for \( x \) in a neighbourhood \( \{x_u : u \in [s, t]\}\)
and let \( \alpha \in \Omega^1(E, E \otimes V) \) be defined by
\[
\alpha(\xi_x) := \varphi(x) \otimes dF(\xi_x) = \varphi(x) \otimes F'(x) \xi \text{ for all } \xi_x \in TE \cong E \times E.
\]
Then \( \alpha|_{TM} = 0 \) and therefore \( \int \alpha(dX) \equiv 0 \). By Theorem 2.14, Lemma 3.19 and the fact that
\( \varphi'(x_u) = I_E \), it follows that
\[
0 \simeq \alpha(x_u) x_{u,v} + \alpha'(x_u) X_{u,v} \simeq [(\varphi' \otimes F')(x_u)] X_{u,v} = I \otimes F'(x_u) X_{u,v}
\]
for $s \leq u \leq v \leq t$ and the left member of equation (3.9) is proved. This also easily proves the left member of equation (3.10) since

$$I_E \otimes Q(x_u)X_{u,v} = [I_E \otimes A_F(x_u)]I_E \otimes F'(x_u)X_{u,v},$$

where $A_F(x) := F'(x)^*(F'(x)F'(x)^*)^{-1} \in \text{Hom}(\mathbb{R}^N, E)$ as in Remark 3.5. The other approximate identities in equations (3.9) and (3.10) follow similarly; one needs only now define $\alpha \in \Omega^1(E, V \otimes E)$ by

$$\alpha(\xi_x) := dF(\xi_x) \otimes \varphi(x) = F'(x)\xi \otimes \varphi(x) \quad \text{for all } \xi_x \in TE \cong E \times E.$$

**Remark 3.21.** The conditions in equations (3.9) and (3.10) are equivalent. Indeed, the proof of Corollary 3.20 has already shown equation (3.9) implies equation (3.10). For the converse direction, we need only observe that $F'(x_u) = F'(x_u)Q(x_u)$ so that, for example,

$$I_E \otimes F'(x_u)X_{u,v} = [I_E \otimes F'(x_u)]I_E \otimes Q(x_u)X_{u,v}.$$

**Corollary 3.22.** If $X = (x, \mathcal{X}) \in WG_p(M)$, then $X_{s, t} \simeq [P_{x_s} \otimes P_{x_t}]X_{s, t}$.

**Proof.** The result follows by observing that

$$X_{s, t} = (P_{x_s} + Q_{x_s}) \otimes (P_{x_t} + Q_{x_t})X_{s, t}$$

and then using equation (3.10) to conclude $(I_E \otimes Q_x)X_{s, t} \simeq 0$, $(Q_x \otimes I_E)X_{s, t} \simeq 0$, and

$$(Q_x \otimes Q_x)X_{s, t} = (I_E \otimes Q_x)(Q_x \otimes I_E)X_{s, t} \simeq 0.$$

The following lemma prepares the definition of the integral of a rough path against smooth 1-forms.

**Lemma 3.23.** Suppose $X \in WG_p(M)$, $U$ is an open neighbourhood of $M$, and $\alpha, \beta \in \Omega^1(U, W)$. If $\alpha|_{TM} = \beta|_{TM}$, then

$$\int \alpha(dX) = \int \beta(dX). \quad (3.11)$$

**Proof.** The 1-form, $\psi := \alpha - \beta \in \Omega^1(U, W)$, vanishes on $TM$ and so by Definition 3.17, $\int \psi(dX) \equiv 0$. As the rough path integral is linear on $\Omega^1(U, W)$ at level one, it immediately follows that

$$0 = \left[\int \psi(dX)\right]_{s, t}^{1} = \left[\int \alpha(dX)\right]_{s, t}^{1} - \left[\int \beta(dX)\right]_{s, t}^{1}.$$

Moreover, by Corollary 3.22,

$$\left[\int \alpha(dX)\right]_{s, t}^{2} \simeq \alpha_{x_s} \otimes \alpha_{x_t}X_{s, t} \simeq \alpha_{x_s} \otimes \alpha_{x_t}[P_{x_s} \otimes P_{x_t}]X_{s, t}$$

$$= \beta_{x_s} \otimes \beta_{x_t}[P_{x_s} \otimes P_{x_t}]X_{s, t} \simeq \beta_{x_s} \otimes \beta_{x_t}X_{s, t}$$

$$\simeq \left[\int \beta(dX)\right]_{s, t}^{2}.$$

The last two displayed equations along with Lemma 2.12 now gives equation (3.11).
Definition 3.24. The rough path integral of a rough path $X \in \text{WG}_p(M)$ along a smooth 1-form $\alpha \in \Omega^1(M, W)$ is defined by

$$\textbf{Y} = \int \tilde{\alpha}(d\textbf{X}) \quad \text{as in Theorem 2.14},$$

(3.12)

where $\tilde{\alpha} \in \Omega^1(U, W)$ is any extension of $\alpha$ to a 1-form on some open neighbourhood $M$ in $E$. [Later, in Proposition 3.29, we will show how to characterise $\tilde{\alpha}$ where we have $\int \alpha(d\textbf{X})$ which implies $\tilde{\alpha}$.

As a corollary, we immediately see that the rough integrals against smooth 1-forms are sufficient to characterise a rough path.

Corollary 3.25. Suppose that $X$ and $Y$ are two elements of $\text{WG}_p(M)$ such that $x = y$, and which satisfy

$$\int \alpha(dX) = \int \alpha(dY)$$

for all $\alpha \in \Omega^1(M, V)$. Then $X = Y$ as elements of $\text{WG}_p(E)$.

Proof. Let $\tilde{\alpha} \in \Omega^1(E, V)$ so that $\tilde{\alpha}$ is a smooth extension of $\alpha = \tilde{\alpha}|_{TM}$. By Lemma 3.23, we have

$$\int_s^t \alpha(d\textbf{X}) = \int_s^t \alpha(d\textbf{Y}) = \int_s^t \tilde{\alpha}(d\textbf{Y}).$$

Let $\tilde{\alpha}_{s,t} := \tilde{\alpha}_{s,t} - \tilde{\alpha}_{s,s}$. It follows that

$$\tilde{\alpha}_{x_0}(x_{s,t}) + \tilde{\alpha}'_{x_0}(\tilde{\textbf{X}}_{s,t}) \simeq \tilde{\alpha}_{x_0}(y_{s,t}) + \tilde{\alpha}'_{x_0}(\tilde{\textbf{Y}}_{s,t})$$

which implies $\tilde{\alpha}'_{x_0}(\tilde{\alpha}_{s,t}) \simeq 0$ for every $\tilde{\alpha} \in \Omega^1(E, V)$ and every $s$ and $t$ in $[0, T]$. If we choose $\tilde{\alpha} \in \Omega^1(E, E \otimes E)$ to be defined by $\tilde{\alpha}(\xi) = \tilde{\alpha}_x = x \otimes \xi$, then $\tilde{\alpha}'_{x_0} [\eta \otimes \xi] = \eta \otimes \xi$ for all $\eta, \xi \in E$. So for this $\tilde{\alpha}$ it follows that $\tilde{\alpha}_{s,t} = \tilde{\alpha}'_{x_0}(\tilde{\alpha}_{s,t}) \simeq 0$ and the result follows from Lemma 2.12. $\square$

Analogous to the Banach space setting every geometric $p$-rough path on a manifold is a weakly geometric $p$-rough path.

Proposition 3.26. For $p \in [2, 3)$ the following holds.

1. We have $G_p(M) \subseteq \text{WG}_p(M)$.
2. Suppose $X \in \text{WG}_p(E)$ and $X \in G_{p'}(M)$ for some $3 > p' > p$, then $X \in \text{WG}_p(M)$.

Proof. Let $X \in G_p(M)$. For the first claim, we note by definition there exists a sequence $x_n$ of smooth paths in $M$ such that the lifts $X_n := S_2(x_n) \in G_p(M) \subseteq G_p(E)$ converge to $X$ in the rough $p$-variation metric on $G_p(E)$. Let $\tilde{\alpha} \in \Omega^1(E, W)$ be such that $\tilde{\alpha}|_{TM} \equiv 0$, then

$$\int \tilde{\alpha}(dx_n) = 0,$$

hence $0 = S_2 \left( \int \tilde{\alpha}(dx_n) \right) = \int \tilde{\alpha}(dX_n) \rightarrow \int \tilde{\alpha}(dX)$

(3.13)

as $n \to \infty$. By definition the trace of $x$ lies in $M$, and it is immediate that we have $X \in \text{WG}_p(M)$.

For the second claim, we approximate $X$ in $p'$ variation to deduce that (3.13) holds provided $\tilde{\alpha}|_{TM} \equiv 0$. $\square$

In the following, we will frequently rely on localisation arguments.

Remark 3.27 (Localisation). Suppose $X = (x, \textbf{X}) \in \text{WG}_p(E)$ has its trace, $x$, lying in $M$. By a simple compactness argument, there exist $k \in \mathbb{N}$, open subsets $U_i$ of $E$ and local defining
functions, $F_i : U_i \to \mathbb{R}^{N-d}$, as in Definition 3.1 for $1 \leq i \leq k$ such that $\{U_i\}_{i=1}^k$ is an open cover of $x([0, T])$. Furthermore, since $x$ is uniformly continuous, we can find $\delta = \delta(X) > 0$, such that, for all $s$ and $t$ in the interval $[0, T]$ with $|s - t| < \delta$, the path segment
\[ \{ x_u : u \in [s, t] \} \subset U_i \] (3.14)
for some $i \in \{1, \ldots, k\}$.

The next result describes the constraints on $x_{s,t}$ which arise when $X \in WG_p(M)$, also see Example 3.30.

**Lemma 3.28.** If $X \in WG_p(M)$, then
\[ Q_{x_s x_{s,t}} \simeq Q_{x_s} (\partial P_{\alpha} \alpha P b)_{a \otimes b = x_{s,t}}. \] (3.15)

**Proof.** Let $\tilde{\alpha}(\xi_s) = Q_F(x) \xi$ so that $\tilde{\alpha} \in \Omega^1(U, E)$. Then $\tilde{\alpha}|_{T(M \cap U)} \equiv 0$ and therefore, by Definition 3.17 and Corollary 3.22,
\[ 0 = \left[ \int_{s,t} (\tilde{\alpha}(dX)) \right]_{s,t} \simeq \tilde{\alpha}_{x_s} (x_{s,t}) + \tilde{\alpha}_{x_t} x_{s,t} \simeq Q_{x_s x_{s,t}} + \tilde{\alpha}_{x_s} (x_{s,t}) \simeq Q_{x_s} (\partial P_{\alpha} \alpha P b)_{a \otimes b = x_{s,t}}. \] (3.16)
Solving equation (3.16) for $Q_{x_s x_{s,t}}$ completes the proof after using the identity,
\[ \tilde{\alpha}_{x_s} (x_{s,t}) + \tilde{\alpha}_{x_t} x_{s,t} = -Q_{x_s} dP (\alpha P b)_{a \otimes b = x_{s,t}}, \] wherein the last inequality made use of Lemma 3.11 and the fact that $P^2 = P$. It is easily seen that this agrees with (3.15). \qed

We conclude this section with a theorem that provides a more explicit description of the integral of 1-forms along $X \in WG_p([0, T], M)$ which require no extensions of the 1-form to the ambient space.

**Proposition 3.29** (Integrating 1-forms without extensions). If $X \in WG_p([0, T], M)$ and $\alpha \in \Omega^1(M, W)$, then
\[ \left[ \int_{s,t} \alpha(dX) \right]_{s,t} \simeq \alpha_{x_s} (x_{s,t}) + (\nabla \alpha)([P_{x_s} \otimes P_{x_t}] x_{s,t}) \] (3.17)
and
\[ \left[ \int_{s,t} \alpha(dX) \right]_{s,t}^2 \simeq \alpha_{x_s} \otimes \alpha_{x_t} [P_{x_s} \otimes P_{x_t}] x_{s,t}, \] (3.18)
where $\nabla \alpha$ is the Levi-Civita covariant derivative of $\alpha$ as in Definition 3.10.

**Proof.** By Definition 3.24,
\[ \int_s^t \alpha(dX) = \int_s^t \tilde{\alpha}(dX) = \left[ \int_{s,t} \tilde{\alpha}(dX) \right]_{s,t} \simeq (\tilde{\alpha}_{x_s} (x_{s,t}) + \tilde{\alpha}_{x_t} x_{s,t}) \simeq (\tilde{\alpha}_{x_s} (x_{s,t}) + \tilde{\alpha}_{x_t} x_{s,t}) \simeq \left[ \alpha_{x_s} \otimes \alpha_{x_t} [P_{x_s} \otimes P_{x_t}] x_{s,t} \right] \] (3.19)
where $\tilde{\alpha}$ is any extension of $\alpha$ to an open neighbourhood of $M$ in $E = \mathbb{R}^N$. By Corollary 3.22, $x_{s,t} \simeq [P_{x_s} \otimes P_{x_t}] x_{s,t}$ and hence we may replace equation (3.19) by
\[ \int_s^t \alpha(dX) \simeq (\tilde{\alpha}_{x_s} (x_{s,t}) + \tilde{\alpha}_{x_t} x_{s,t}) \simeq (\tilde{\alpha}_{x_s} (x_{s,t}) + \tilde{\alpha}_{x_t} x_{s,t}) \simeq (\alpha_{x_s} \otimes \alpha_{x_t} [P_{x_s} \otimes P_{x_t}] x_{s,t}). \] (3.20)
Let us now use Remark 3.2 to locally extend $P$ to a neighbourhood of $M$ so that $P = P \circ \pi$. By replacing $\tilde{\alpha}$ by $\tilde{\alpha}P$ if necessary, we may assume $\tilde{\alpha} = \tilde{\alpha}P$. Under this assumption, equation
(3.21) becomes

$$
\int_s^t \alpha(dX) \simeq (\alpha_{x_s}(P_{x_s}x_{s,t}) + \tilde{\alpha}_{x_s}([P_{x_s} \otimes P_{x_s}]X_{s,t}, \alpha_{x_s} \otimes \alpha_{x_s}[P_{x_s} \otimes P_{x_s}]X_{s,t})).
$$

(3.22)

From item 4 of Proposition 3.12,

$$
\tilde{\alpha}_m[v \otimes w] = (\nabla_v \alpha)(w) \quad \text{for all } v, w \in T_mM
$$

which combined with equation (3.22) proves equations (3.17) and (3.18).

3.3. Characterising weakly geometric rough paths on $M$

The goal of this subsection is to show $X = (x, X) \in WG_p(E)$ is in $WG_p(M)$ if and only if $x_t \in M$ for all $0 \leqslant t \leqslant T$ and that either of the equivalent equations (3.9) or (3.10) holds locally. This will be carried out in Proposition 3.35. The next example shows that the result in Lemma 3.28 is really about paths in $x_t \in M$ and not so much about its augmentation to a rough path.

**Example 3.30.** Let $x_t$ be any path $M$ with $|x_{s,t}| \leqslant C \omega(s, t)^{1/p}$. Then

$$
0 = [F(x)]_{st} = F'(x_{s,t})x_{s,t} + \frac{1}{2} F''(x_{s,t})x_{s,t} \otimes x_{s,t} + O(|x_{s,t}|^2)
$$

$$
\simeq F'(x_{s,t})x_{s,t} + \frac{1}{2} F''(x_{s,t})[x_{s,t} \otimes x_{s,t}].
$$

Applying $A_F(x_s) \in \text{Hom}(\mathbb{R}^{N-d}, E)$ (see Remark 3.5) to this equation then shows

$$
Q(x_s)x_{s,t} \simeq -\frac{1}{2} A_F(x_s)F''(x_s)[x_{s,t} \otimes x_{s,t}],
$$

(3.23)

From this equation it follows that $x_{s,t} = P(x_s)x_{s,t} + O(|x_{s,t}|^2)$ and so we may replace $x_{s,t} \otimes x_{s,t}$ in equation (3.23) by $P(x_s)x_{s,t} \otimes P(x_s)x_{s,t}$, which allows us to rewrite equation (3.23) as

$$
Q(x_s)x_{s,t} \simeq -\frac{1}{2} A_F(x_s)F''(x_s)[P(x_s)x_{s,t} \otimes P(x_s)x_{s,t}],
$$

(3.24)

So if $x_t \in M$ for all $t$, the component of $x_{s,t}$ orthogonal to $\tau_{x,t}M$ is determined modulo terms of order $|x_{s,t}|^3$ by knowing the component of $x_{s,t}$ tangential to $M$ at $x_s$.

**Lemma 3.31.** Suppose $X = (x, X) \in WG_p(E)$ such that $x_t \in M$ for all $t \in [0, T]$; then

$$
(I \otimes Q(x_s))[X_{s,t}]^a \simeq 0.
$$

(3.25)

**Proof.** Note that by the definition of $\simeq$ it is sufficient to check (3.25) locally for all $0 < s < t < T$ such that $|t - s| < \delta$ and some $\delta > 0$. Let $\{U_i : i = 1, \ldots, k\}$ and $F_i$ as in Remark 3.27 be a cover of the trace $x$. By construction of the cover for all $0 \leqslant s < t \leqslant T$ with $|s - t| < \delta$ there exists $U_i$ such that (3.14) holds. By (3.1), we may assume that, for $m \in U_i$, we have $Q(m) = A(m)F_i(m)$, where $A(m) := F_i'(m)^*(F_i'(m)F_i'(m)^*)^{-1}$. From equation (2.6) which holds by definition of $X$ being in $WG_p(E)$, it follows that

$$
(I \otimes Q(x_s))[X_{s,t}]^a = \frac{1}{2} (I \otimes Q(x_s))x_{s,t} \otimes x_{s,t} = \frac{1}{2} x_{s,t} \otimes A(x_s)F_i'(x_s)x_{s,t}.
$$

Applying item 1 of Lemma 3.18 to the right member of this equation gives the estimate

$$
|(I \otimes Q(x_s))[X_{s,t}]^a| \leqslant \frac{1}{2} |A(x_s)||x_{s,t}||F_i'(x_s)x_{s,t}| \leqslant C|x_{s,t}|^3 \simeq 0.
$$

**Corollary 3.32.** If $X$ is an element of $WG_p(E)$ such that the trace $x$ is in $M$, then the following are equivalent:

1. $(I_E \otimes Q(x_s))[X_{s,t}]^a \simeq 0$;
2. $(I_E \otimes Q(x_s))[X_{s,t}] \simeq 0$;
(3) \((I_E \otimes F'(x_s))[X_{s,t}] \simeq 0\) over the interval \([u,v]\), whenever \(F\) is a local defining function for \(M\) on \(U\) in the sense of Definition 3.1, and the path segment of \(x\) over \([u,v]\) satisfies
\[
\{x_r : r \in [u,v]\} \subset U.
\]

**Proof.** The equivalence of items 1 and 2 is an immediate corollary of Lemma 3.31. The equivalence of items 2 and 3 is the content of Remark 3.21.

**Remark 3.33.** If \(X \in \text{WG}_p(E)\), then the condition \((I_E \otimes Q(x_s))[X_{s,t}] \simeq 0\) is equivalent to the condition that \((Q(x_s) \otimes I_E)[X_{s,t}] \simeq 0\), that is, it does not matter in which slot the projection acts. To see this is the case, we let \(F : E \otimes E \to E \otimes E\) denote the linear flip operator determined by \(Fa \otimes b = b \otimes a\) for all \(a, b \in E\). Then
\[
F(Q(x_s) \otimes I_E)[X_{s,t}] = (I_E \otimes Q(x_s))[F[X_{s,t}]]
\]
\[
= (I_E \otimes Q(x_s))[FX_{s,t}^a + FX_{s,t}^b]
\]
\[
= (I_E \otimes Q(x_s))[X_{s,t}^a - X_{s,t}^b]
\]
\[
\simeq (I_E \otimes Q(x_s))[-X_{s,t}^a - X_{s,t}^b]
\]
\[
= -(I_E \otimes Q(x_s))[X_{s,t}]
\]
where in the second to last line we have used \(I_E \otimes Q(x_s)X_{s,t}^a = \frac{1}{2}x_{s,t} \otimes Q(x_s)x_{s,t} \simeq 0\).

The next proposition shows Definition 3.17 and Definition 3.34 for the notion of a weakly geometric rough path are equivalent.

**Definition 3.34 (Projection definition of weakly geometric rough paths).** We say that \(X = (x, X)\) is a weakly geometric \(p\)-rough path on the manifold \(M\) if \(X\) is in \(\text{WG}_p(E)\), its trace \(x\) lies in \(M\) and \(X\) satisfies
\[
(I_E \otimes Q(x_s))[X_{s,t}]^a \simeq 0 \simeq (I_E \otimes Q(x_s))X_{s,t},
\]
wherein \(Q\) is the orthogonal projection onto the normal bundle as in Notation 3.3 and \(I_E\) is the identity map on \(E\).

**Proposition 3.35** (The projection characterisation of \(\text{WG}_p(M)\)). Let \(X = (x, X) \in \text{WG}_p(E)\); then \(X \in \text{WG}_p(M)\) (Definition 3.17) if and only the trace \(x\) is in \(M\) and any one of the equivalent conditions in Corollary 3.32 holds.

**Proof.** \((\implies\) ) This implication has already been demonstrated in Corollary 3.20 and Remarks 3.21 and 3.27. 
\((\iff\) ) For the converse implication assume \(x_t \in M\) for all \(t \in [0,T]\) and (again, locally)
\[
[I_E \otimes F'(x_s)][X_{s,t}] \simeq 0 \quad \text{and} \quad [I_E \otimes Q(x_s)][X_{s,t}] \simeq 0.
\]
We have to show, for any finite-dimensional vector space \(W\), that
\[
\int_{\Omega^1(E,W)} \alpha = 0 \quad \forall \alpha \in \Omega^1(E,W) \ni \alpha|_{T,M} \equiv 0.
\]
The proof will proceed in several stages, considering first 1-forms with specific structures, and finally combining those results to deduce the general claim. In what follows, we let
\[
Y = (y, Y) := \int \alpha(dX)
\]
and let \(Q, Q_F\) and \(A_F\) be as in Notation 3.3 and Remarks 3.4 and 3.5.

**Case 1.** We begin by supposing that \(\alpha = \varphi dF = \varphi F' \in \Omega^1(E,W)\) for some \(\varphi \in C^\infty_c(E, \text{Hom}(V,W))\) with \(\text{supp}(\varphi) \subset U\). By equation (3.5) of Lemma 3.19 and equation (2.7),
we learn that
\[ y_{s,t} \simeq \alpha(x_s)x_{s,t} + \alpha'(x_s)X_{s,t} \simeq [\varphi'(x_s) \cdot F'(x_s)]X_{s,t} \simeq 0 \tag{3.29} \]
where, for the last approximation, we have used the assumption on equation (3.27). Similarly,
\[ Y_{s,t} \simeq \alpha(x_s) \otimes \alpha(x_s)X_{s,t} = [\varphi(x_s) \otimes \varphi(x_s)] [F'(x_s) \otimes I_E][I_E \otimes F'(x_s)]X_{s,t} \simeq 0. \tag{3.30} \]
Equations (3.29) and (3.30) along with Lemma 2.12 shows \( y_{s,t} = 0 \) and \( Y_{s,t} \equiv 0 \) for all \( s \) and \( t \).

Case 2. Now suppose \( \alpha = \beta \circ Q_F \), where \( \beta \in \Omega^1(E,W) \) is any 1-form on \( E \). Then locally we have
\[ \alpha(x)\xi = \beta(x)Q_F(x)\xi = \beta(x)A_F(x)F'(x)\xi = \varphi(x)F'(x)\xi, \]
where \( \varphi(x) := \beta(x)A_F(x) \). We conclude by using case 1 and a suitable application of Remark 3.27.

Case 3. Now assume that \( \beta \in \Omega^1(E,W) \) is a 1-form such that \( \beta(m) \equiv 0 \) for all \( m \in M \). If \( \sigma(t) \) is a path in \( M \), then \( \beta(\sigma(t)) = 0 \) and therefore \( 0 = (d/dt)\beta(\sigma(t)) = \beta'(\sigma(t))\delta(t) \). Since \( \sigma(t) \in M \) is arbitrary, it follows that \( \partial_{v_m}\beta = 0 \) for all \( v_m \in T_mM \). Hence we conclude that
\[ (\partial \xi)\beta = (\partial_{P_m}\xi)\beta + (\partial_{Q_m}\xi)\beta = (\partial_{Q_m}\xi)\beta \quad \forall \ m \in M \text{ and } \xi \in E = \mathbb{R}^N \]
or in other words,
\[ \beta'(m) = \beta'(m)[Q(m) \otimes I_E] \quad \text{for all } m \in M. \]
With this in hand, using Lemma 3.18 and equation (3.27) again, we find that
\[ \left[ \int \beta(dX) \right]_{s,t}^1 \simeq \beta(x_s)x_{s,t} + \beta'(x_s)X_{s,t} = \beta'(x_s)[Q(x_s) \otimes I_E]X_{s,t} \simeq 0. \tag{3.31} \]
As usual, this together with the additivity of the trace shows \( \int \beta(dX)_{s,t}^1 = 0 \). Then, working as above, the second-order process is given by
\[ \left[ \int \beta(dX) \right]_{s,t}^2 \simeq [\beta(x_s) \otimes \beta(x_s)]X_{s,t} = [0 \otimes 0]X_{s,t} = 0. \]

Case 4. Finally, if \( \alpha \) is any 1-form on \( E \) with the property that \( \alpha|_{TM} \equiv 0 \), then \( \alpha = \alpha \circ Q_F \) on \( M \). (A slightly subtle point here is that \( \alpha = \alpha \circ Q \) on \( M \) but not necessarily on a neighbourhood of \( M \). For this reason, we cannot directly use case 2 here.) We now let \( \beta := \alpha - \alpha \circ Q_F \) so that \( \beta(m) \equiv 0 \) for all \( m \in M \). Thus we have decomposed \( \alpha \) as \( \alpha = \beta + \alpha \circ Q_F \) where \( \beta \equiv 0 \) on \( M \) and therefore, by cases 2 and 3,
\[ y := \left[ \int \alpha(dX) \right]_{s,t}^1 \simeq \left[ \int \beta(dX) \right]_{s,t}^1 + \left[ \int (\alpha \circ Q_F)(dX) \right]_{s,t}^1 = 0 + 0 = 0. \]
We further have, using
\[ \alpha_m = \beta_m + \alpha_mQ_m = \alpha_mQ_m \quad \forall \ m \in M, \]
and equation (3.27), that
\[ \left[ \int \alpha(dX) \right]_{s,t}^2 \simeq [\alpha_{x_s}Q_{x_s} \otimes \alpha_{x_s}Q_{x_s}]X_{s,t} = [\alpha_{x_s} \otimes Q_{x_s}][I_E \otimes Q_{x_s}][Q_{x_s} \otimes I_E]X_{s,t} \simeq 0. \]
An application of Lemma 2.12 then shows \( \Xi_{s,t} \equiv 0 \). \( \square \)

The defining property in equation (3.26) is local and we therefore need a remark analogous to Lemma A.1, which allows us to concatenate rough paths on manifolds.
Remark 3.36 (Gluing). Suppose that \( D = \{0 = t_0 < t_1 < \cdots < t_n = T\} \) is any partition of \([0,T]\). Let \( \delta > 0 \), and suppose that the overlapping intervals \( J_k \) for \( 1 \leq k \leq n \) are defined by

\[
J_k = [t_{k-1}, \min(t_k + \delta, T)].
\]

Assume, for each \( k \), \( J \) of rough paths on manifolds under sufficiently smooth maps. Analogous to the Banach space setting (see Subsection A.2) we may consider the pushforward

\[
\text{Pushforwards and independence of the choice of embedding}
\]

Analogous to the Banach space setting (see Subsection A.2) we may consider the pushforward of rough paths on manifolds under sufficiently smooth maps.

Definition 3.37 (Pushedforward rough paths). Let \( M \) and \( N \), respectively, be smooth embedded submanifolds of the Euclidean spaces \( E \) and \( E' \). Suppose that \( \varphi : M \to N \) is smooth and let \( d\varphi \in \Omega^1(M, E') \), that is, we regard \( d\varphi \) as an \( E' \)-valued 1-form. Then if \( X \) is an element of \( WG_p(M) \), we define the pushedforward rough path \( \varphi_* (X) \) in \( E' \) by setting

\[
\varphi_* (X) := \int d\varphi (dX) = \int \varphi'(x) \, dX,
\]

and taking the starting point to be \( \varphi(x_0) \).

Proposition 3.38 (Pushing forward rough paths). Let \( X \in WG_p(M) \). The rough path \( \varphi_* X \) in Definition 3.37 satisfies:

1. \([\varphi_* X]_{s,t}^1 = \varphi(x_t) - \varphi(x_s) \in E' \) for all \( s, t \in [0,T] \);
2. \( \varphi_* X \) is an element of \( WG_p(N) \);
3. if \( L \) is another smooth submanifold which is embedded in the Euclidean space \( E'' \) and if \( \psi : N \to L \) is a smooth map, then

\[
\psi_* [\varphi_* X] = [\psi \circ \varphi]_* (X);
\]

4. if \( \beta \in \Omega^1(N,V) \), then

\[
\int \beta (d[\varphi_* (X)]) = (\varphi^* \beta)(dX).
\]

Proof. We take each item in turn.

1. If \( \varphi : M \to N \) is a smooth map between embedded submanifolds, then it may be viewed (at least locally) as the restriction of a smooth map from \( \Phi : E \to E' \). It then follows that \( d\Phi \) is an extension of \( d\varphi \) to a neighbourhood of \( M \) and therefore, by Definition 3.24, \( \varphi_* (X) = \Phi_* (X) \), and hence from Lemma A.4 we have that

\[
[\varphi_* (X)]_{s,t}^1 = [\Phi_* (X)]_{s,t}^1 = \Phi(x_t) - \Phi(x_s) = \varphi(x_t) - \varphi(x_s).
\]

2. Since \( \varphi_* (X) = \Phi_* (X) \), it follows that \( \varphi_* (X) \in WG_p(E') \). Moreover, if \( \alpha \in \Omega^1(E', W) \) is such that \( \alpha|_{TN} \equiv 0 \), then by Theorem A.5

\[
\int \alpha (d[\varphi_* (X)]) = \int \alpha (d[\Phi_* (X)]) = \int [\alpha \circ \Phi'] dX = 0
\]

as \( \alpha \circ \Phi' = \Phi^* \alpha \in \Omega^1(E, W) \) which vanishes on \( TM \). We deduce from Definition 3.17 and 1. that \( \varphi_* (X) \in WG_p(N) \).
(3) Follows by a similar argument to 2, using Corollary A.6.

(4) This is a consequence of Theorem A.5 (once again using that \( \varphi_*(X) = \Phi_*(X) \), and the fact that \( \Phi^* \beta \) restricts to \( \varphi^* \beta \).

\[ \square \]

**Example 3.39.** Suppose that \( \varphi : M \to M \) is the identity map; then \( \varphi = \Phi|_E \), where \( \Phi : E \to E \) is the identity map and therefore,

\[ \varphi_*(X) = \int d\varphi(dX) = \int d\Phi(dX) = X. \]

The preceding example is a special case of the more general fact that diffeomorphisms give rise to bijections between the respective sets of weakly geometric rough paths on two embedded manifolds. The following corollary is immediate from Proposition 3.38.

**Corollary 3.40.** Let \( M, N \) be embedded manifolds and \( \varphi : M \to N \) be a diffeomorphism. Then the function \( \varphi_* \) is a bijection between \( WG_p(M) \) and \( WG_p(N) \).

Suppose now \( \mathcal{M} \) is an abstract manifold embedded as \( M \) and \( \tilde{M} \) in two vector spaces \( E \) and \( \tilde{E} \), respectively. Then there exist smooth maps \( f : \mathcal{M} \to E \) and \( \tilde{f} : \mathcal{M} \to \tilde{E} \) diffeomorphic onto their image such that \( f(M) = M \) and \( \tilde{f}(M) = \tilde{M} \). The following corollary shows that we have a natural identification between the rough paths on \( M \) and \( \tilde{M} \). The map we construct is natural in the sense that it respects the integration of 1-forms (characterising the rough paths; cf. Corollary 3.25).

**Corollary 3.41.** Let \( \mathcal{M}, M, \tilde{M} \) be as above. Then the pushforward \((\tilde{f} \circ f^{-1})_* \) is a bijective map from \( WG_p(M) \) to \( WG_p(M) \) such that, for any finite-dimensional vector space-valued 1-form \( \alpha \in \Omega^1(\mathcal{M}, W) \) and any \( X \in WG_p(M) \)

\[ \int((f^{-1})^*\alpha)(dX) = \int((\tilde{f} \circ f^{-1})^*\alpha)(d([\tilde{f} \circ f^{-1}]*X)). \]

**Definition 3.42** (Abstract weakly geometric rough paths). Let \( \mathcal{M} \) be an abstract manifold and suppose that \( f : \mathcal{M} \to M \subset E \) and \( \tilde{f} : \mathcal{M} \to \tilde{M} \subset \tilde{E} \) are two embeddings of \( \mathcal{M} \) into Euclidean spaces \( E \) and \( \tilde{E} \), respectively. We say that \((f, X)\) and \((\tilde{f}, \tilde{X})\), where \( X \in WG_p(M) \) and \( \tilde{X} \in WG_p(M) \), are equivalent. This is an equivalence relation because of item 3 of Proposition 3.38. The equivalence class associated to

\[ \tilde{X} = (\tilde{f} \circ f^{-1})_*(X). \]

The equivalence class associated to \((f, X)\) will be denoted by \([(f, X)]\). The weakly geometric rough paths on \( \mathcal{M} \) is the collection of these equivalence classes;

\[ WG_p(\mathcal{M}) := \{ [(f, X)] : X \in WG_p(M) \}. \]

If \( \alpha \in \Omega^1(\mathcal{M}, W) \) and \([(f, X)] \in WG_p(\mathcal{M}) \), then we define

\[ Z_{[(f, X)]}(\alpha) := \int \alpha([f, X]) := \int((f^{-1})^*\alpha)(dX) \in WG_p(W). \]

Because of Corollary 3.40, \( Z_{[(f, X)]} \) is well defined and because of Corollary 3.25, knowledge of \( f \) and \( Z_{[(f, X)]} \) uniquely determines \( X \). The functionals \( Z_{[(f, X)]} \) are closely related to the notion of manifold-valued rough paths as introduced in [5]. An alternative, more explicit, proof of the independence of the embedding for the rough paths will be given in a forthcoming paper by Cass, Driver, and Litterer where another intrinsic notion of rough paths will be developed.
4. RDEs on manifolds and consequences

In this section, we consider RDEs constrained to $M$; see Definition 4.1. Theorem 4.2 gives the basic existence uniqueness results for constrained RDEs. The extrinsic Definition 4.1 is shown in Theorem 4.5 to be equivalent to a pair of intrinsic notions of solutions for constrained RDEs. In Example 4.12, we use constrained RDEs to give examples of weakly geometric rough paths on $M$ and then in Theorem 4.18 we show that all $X \in WG_p(M)$ arise as in Example 4.12. The relationships between $WG_p(M)$ and $G_p(M)$ is spelled out in Theorem 4.17 and a summary of all of our characterisations of $WG_p(M)$ is then given in Theorem 4.18. As an illustration of our results, in Subsection 4.3 we study RDEs on a Lie group $G$ whose dynamics are determined by right invariant vector fields on $G$. This added right invariance assumption guarantees that the resulting RDEs have global solutions; see Theorem 4.20.

4.1. Rough differential equations on $M$

**Definition 4.1 (Constrained RDE).** Let $x_0 \in M$, $Y : \mathbb{R}^n \to \Gamma(TM)$ be a linear function, and $Z \in WG_p(\mathbb{R}^n)$ be given. We say $X \in WG_p(M)$ solves the RDE
\[ dX_t = Y_{\partial Z}(x_t) \quad \text{with} \quad x(0) = x_0 \in M, \tag{4.1} \]
provided
\[ x_{s,t} \simeq Y_{z_{s,t}}(x_s) + (\partial_y Y_b)(x_s)|_{a \otimes b = z_{s,t}} \quad \text{and} \]
\[ X_{s,t} \simeq Y_a(x_s) \otimes Y_b(x_s)|_{a \otimes b = z_{s,t}}. \tag{4.2} \]

Note that $Y_a(x_s) \in T_{x_s}M$ and therefore there exists a smooth curve $\sigma(t) \in M$ such that $\dot{\sigma}(0) = Y_a(x_s)$ and we then compute $(\partial_y Y_b)(x_s)$ using
\[ (\partial_y Y_b)(x_s) = \left. \frac{d}{dt} \right|_0 Y_b(\sigma(t)) \in E. \]

This comment shows that the above definition makes sense but it is not yet clear that there is a (local in time) solution to the RDE (4.1). If $X \in WG_p(M)$ solves equation (4.1), $U$ is an open (in $E$) neighbourhood of $M$ and $Y : \mathbb{R}^n \to \Gamma(TU)$ is a linear map such that $Y_a = Y_a$ on $M$, then $X$ solves the standard Euclidean space RDE
\[ dX_t = \tilde{Y}_{\partial Z}(x_t) \quad \text{with} \quad x(0) = x_0 \in M. \tag{4.4} \]

From these considerations, we see that if there exists $X \in WG_p(M)$ solving equation (4.1), then this solution may be described as the unique solution $X \in WG_p(E)$ to equation (4.4). We will use this remark in our proof of the existence Theorem 4.2 below to equation (4.1). Once this is accomplished, we develop in Theorem 4.5 alternative intrinsic characterizations of solutions to the RDE in equation (4.1).

**Theorem 4.2.** There is a unique solution $X \in WG_p(M)$ (possibly up to explosion time) of the RDE (4.1). Moreover, either $X$ exists on all of $[0,T]$ or there exists a $\tau \in [0,T]$ such that $X$ exists on $[0,\tau)$ and $\{x(t) : 0 \leq t < \tau\}^M$ is not compact in $M$.

**Proof.** Let $U$ be a neighbourhood of $x_0 \in M$ and $F : U \to \mathbb{R}^k$ be a local defining function of $M$ as in Definition 3.1. We then let $Y_a := P_F[Y_a \circ \pi]$, where $\pi$ is as in Remark 3.2 and $P_F$ is the projection map in Notation 3.3. Let $X = (x, \tilde{X}) \in WG_p(E)$ be the RDE solution to equation (4.4) defined up to the first exit time $\tau$ from $U$ where we let $\tau = \infty$ if $x_t \in M$ for all $0 \leq t \leq T$. We are now going to show $x(t) \in M \cap U$ for $0 \leq t < \tau$.

**ACKNOWLEDGMENTS:**
This research was supported by the National Science Foundation under Grant No. DMS-1265436.
Note by construction that \( \hat{Y}_b = Y_b \) on \( M \cap U \) and \( F' \hat{Y}_b = 0 \) on \( U \). Differentiating this last equation along \( \xi = \hat{Y}_a \) then further implies

\[
F'' \hat{Y}_b \otimes \hat{Y}_b + F' \partial \varphi_a \hat{Y}_b = 0. \tag{4.5}
\]

Recall that \( X \) solves equation (4.4) if and only if

\[
x_{s,t} \simeq \hat{Y}_{z,s,t}(x_s) + (\partial \varphi_a(x_s)) \hat{Y}_b(x_s)|_{a \otimes b = Z_{s,t}} \quad \text{and} \quad X_{s,t} \simeq [\hat{Y}(x_s) \otimes \hat{Y}(x_s)]|_{Z_{s,t}}. \tag{4.6}
\]

Using the first approximate identity in equation (4.6) along with \( F' \hat{Y} = 0 \) shows

\[
[F(x)]_{s,t} := F(x_t) - F(x_s) = F(x_s + x_{s,t}) - F(x_s) \\
\simeq F'(x_s)x_{s,t} + \frac{1}{2} F''(x_s)x_{s,t} \otimes x_{s,t} \\
\simeq F'(x_s)[\hat{Y}_{z,s,t}(x_s) + (\partial \varphi_a(x_s)) \hat{Y}_b(x_s)|_{a \otimes b = Z_{s,t}}] + \frac{1}{2} F''(x_s)[\hat{Y}_{z,s,t}(x_s) \otimes \hat{Y}_{z,s,t}(x_s)] \\
= F'(x_s)(\partial \varphi_a(x_s) \hat{Y}_b(x_s)|_{a \otimes b = Z_{s,t}} + \frac{1}{2} F''(x_s)[\hat{Y}_{z,s,t}(x_s) \otimes \hat{Y}_{z,s,t}(x_s)]. \tag{4.7}
\]

Since \( F''(x_s) \) is symmetric and \( Z \) is a geometric rough path, it follows that equation (4.5) and

\[
\frac{1}{2} F''(x_s)[\hat{Y}_{z,s,t}(x_s) \otimes \hat{Y}_{z,s,t}(x_s)] = F''(x_s)[\hat{Y}_a(x_s) \otimes \hat{Y}_b(x_s)|_{a \otimes b = Z_{s,t}}. \tag{4.8}
\]

Combining equations (4.5), (4.7), and (4.8) shows \( [F(x)]_{s,t} \simeq 0 \), which implies that \( F(x_t) \) is constant in \( t \in [0, \tau] \). Since \( F(x_0) = 0 \), it follows that \( F(x_t) = 0 \) for \( t < \tau \), that is, \( x(t) \in M \) for 

\[t < \tau. \]

Also note that

\[I \otimes Q(x_s)X_{s,t} \simeq I \otimes Q(x_s)[\hat{Y}(x_s) \otimes \hat{Y}(x_s)]|_{Z_{s,t}} \simeq 0,
\]

and therefore \( X \in WG_p([0, \tau], M) \) and we have proved local existence to equation (4.4). This shows local existence to equation (4.1).

Suppose that we have found \( X \in WG_p([0, \tau], M) \) solving equation (4.1) on \([0, \tau)\) for some \( \tau < T \). If there exists a compact subset \( K \subset M \) such that \( \{x(t) : t < \tau \} \subset K \), then there exists \( t_n \in [0, \tau) \) such that \( t_n \uparrow \tau \) and \( x_\infty := \lim_{n \to \infty} x(t_n) \) exists in \( K \subset M \). We now let \( U \) be a precompact neighbourhood of \( x_\infty \in M \) and \( F : U \to \mathbb{R}^k \) be a local defining function of \( M \) as in Definition 3.1 and, as above, let \( Y_a := P_F[|a| \otimes \pi] \) on \( U \). Moreover, we may assume that \( Y \) is compactly supported. By Corollary 2.17, there exists an \( \varepsilon > 0 \) and a neighbourhood \( V \subset U \) of \( x_\infty \) such that, for any \( s \in [\tau - \varepsilon, \tau] \) and \( y \in V \), there exists \( \hat{X} \in WG_p([s, \tau + \varepsilon], E) \) with trace in \( U \) solving

\[d\hat{X}_t = \hat{Y}_d z_r(x_t) \quad \text{with} \quad x_s = y \in V.
\]

We then choose \( n \) sufficiently large so that \( t_n \in [\tau - \varepsilon, \tau] \) and let \( \hat{X} \in WG_p([t_n, \tau + \varepsilon], E) \) solve the previous equation with \( y = x(t_n) \). We may now apply the concatenation Lemma A.2 to glue \( X \) and \( \hat{X} \) together to show that there exists a solution to equation (4.1) on \([0, \tau + \varepsilon]\).

Let us now consider the case where equation (4.1) does not admit a global solution defined on \([0, T]\). In this case, let

\[\tau = \sup\{T_0 \in (0, T) : \exists \hat{X} \in WG_p([0, T_0], M) \text{ solving (4.1)} \} \in (0, T]\]

and, for \( 0 \leq s \leq t < \tau \), let \( X_{s,t} := \hat{X}_{s,t} \), where \( \hat{X} \in WG_p([0, T_0], M) \) solves equation (4.1) on \([0, T_0]\) for some \( T_0 \in (t, \tau) \). By the uniqueness part of Theorem 2.16, \( \{X_{s,t} : 0 \leq s \leq t < \tau\} \) is well-defined and satisfies equation (4.1) on \([0, \tau]\). If (for the sake of contradiction) \( \{x(t) : 0 \leq t < \tau\} \) were compact, then the procedure above allows us to produce a solution \( \hat{X} \) to equation (4.1) which is valid on \([0, \min(\tau + \varepsilon, T)]\), which would violate either the definition of \( \tau \) or the assumption that no global solution to equation (4.1) exists on \([0, T]\). Hence we must conclude that \( \{x(t) : 0 \leq t < \tau\} \) is not compact. \( \square \)
We now prepare an equivalent intrinsic characterisations of an RDE solution. The following proposition is a consequence of the universality property of the full tensor algebra, 

\[ T(\mathbb{R}^n) = \mathbb{R} \oplus \mathbb{R}^n \otimes_k \mathbb{R}^n, \]

over \( \mathbb{R}^n \).

**Proposition 4.3.** Let \( \mathcal{L}(M) \) denote the collection of all linear differential operators on \( C^\infty(M) \). If \( Y : \mathbb{R}^n \to \Gamma(TM) \) is a linear map, then \( Y \) extends uniquely to an algebra homomorphism, \( Y : T(\mathbb{R}^n) \to \mathcal{L}(M) \) such that \( Y_1 := Id \in \mathcal{L}(M) \), where \( 1 \in T(\mathbb{R}^n) \).

**Example 4.4.** If \( A \in \mathbb{R}^n \otimes \mathbb{R}^n \), then \( Y_A = Y_aY_b|_{a \otimes b = A} \), wherein we are using the conventions introduced in Notation 2.2.

**Theorem 4.5.** Let \( Y : \mathbb{R}^n \to \Gamma(TM) \) be a linear map and \( X \in \text{WG}_p(M) \). Then the following are equivalent:

1. \( X \) solves the RDE in equation (4.1);
2. for any finite-dimensional vector space \( W \) and any \( \alpha \in \Omega^1(M,W) \),

\[
\left[ \alpha(dX) \right]_{s,t}^1 \simeq \alpha_x(Y_{z_{s,t}}(x_s)) + [Y_a(x_s)\alpha(Y_b)]|_{a \otimes b = z_{s,t}},
\]

and

\[
\left[ \alpha(dX) \right]_{s,t}^2 \simeq [\alpha_xY_a(x_s) \otimes \alpha_xY_b(x_s)]|_{a \otimes b = z_{s,t}};
\]

3. for any finite-dimensional vector space \( W \) and any \( f \in C^\infty(M,W) \),

\[
f(x_t) - f(x_s) \simeq (Y_{z_{s,t}}f)(x_s)
\]

and

\[
(df \otimes df)([P_{s,x} \otimes P_{s,z}]X_{s,t}) \simeq Y_a f(x_s) \otimes Y_b f(x_s)|_{a \otimes b = z_{s,t}}.
\]

**Proof.** We will show 1. \( \implies \) 2. \( \implies \) 3. \( \implies \) 1.

(1. \( \implies \) 2.) From equations (3.17), (4.2), and (4.3),

\[
\left[ \alpha(dX) \right]_{s,t}^1 \simeq \alpha_x(P_{s,z}x_{st}) + (\nabla \alpha)([P_{s,z} \otimes P_{s,z}]X_{s,t})
\]

\[
\simeq \alpha_x(P_{s,z}[Y_{z_{s,t}}(x_s) + (\partial Y_a Y_b)(x_s)]|_{a \otimes b = z_{s,t}})
\]

\[
+ (\nabla \alpha)([P_{s,z} \otimes P_{s,z}]Y_a(x_s) \otimes Y_b(x_s)|_{a \otimes b = z_{s,t}})
\]

\[
\simeq \alpha_x(Y_{z_{s,t}}(x_s) + P_{s,z}(\partial Y_a Y_b)(x_s)|_{a \otimes b = z_{s,t}}) + (\nabla \alpha)(Y_a(x_s) \otimes Y_b(x_s)|_{a \otimes b = z_{s,t}})
\]

\[
\simeq \alpha_x(Y_{z_{s,t}}(x_s) + \nabla Y_a(x_s)Y_b|_{a \otimes b = z_{s,t}}) + (\nabla \alpha)(Y_b(x_s))|_{a \otimes b = z_{s,t}}.
\]

Combining this approximate identity with the product rule for covariant derivatives in item 2 of Proposition 3.12 gives equation (4.9). Equation (4.10) follows easily from equations (3.18) and (4.3):

\[
\left[ \alpha(dX) \right]_{s,t}^2 \simeq \alpha_x \otimes \alpha_x[P_{s,z} \otimes P_{s,z}]X_{s,t}
\]

\[
\simeq \alpha_x \otimes \alpha_x[P_{s,z} \otimes P_{s,z}][Y_a(x_s) \otimes Y_b(x_s)]|_{a \otimes b = z_{s,t}}
\]

\[
\simeq \alpha_x \otimes \alpha_x[Y_a(x_s) \otimes Y_b(x_s)]|_{a \otimes b = z_{s,t}},
\]

wherein we have used \( P_{s,z}Y_{(z)}(x_s) = Y_{(z)}a(x_s) \) in the last equality.
(2 $\implies$ 3) Applying item 2 with $\alpha = df$ shows

\[
\left[ \int \alpha(dX) \right]_{s,t}^1 \simeq df_{x_s}(Y_{z_{s,t}}(x_s)) + [Y_a(x_s) df_{x_s}(Y_b)]|_{\alpha \otimes b = Z_{s,t}} \\
\simeq df_{x_s}(Y_{z_{s,t}}(x_s)) + [Y_b Y_a f(x_s)]|_{\alpha \otimes b = Z_{s,t}} \\
= (Y_{z_{s,t}+Z_{s,t}} f)(x_s)
\]

and

\[
\left[ \int \alpha(dX) \right]_{s,t}^2 \simeq [df_{x_s} Y_a(x_s) \otimes df_{x_s} Y_b(x_s)]|_{\alpha \otimes b = Z_{s,t}}.
\]

This shows that item 3 holds once we recall that

\[
\left[ \int df(dX) \right]_{s,t}^1 = f_s(X)_{s,t} = f(x_t) - f(x_s)
\]

and

\[
\left[ \int df(dX) \right]_{s,t}^2 \simeq df_{x_s} \otimes df_{x_s}[P_{x_s} \otimes P_{x_s}]X_{s,t}.
\]

(3 $\implies$ 1) Let $W = E$ and $f : M \to E$ be the restrictions of the identity map on $E$, that is, $f(x) = x$ for all $x \in M$. For this $f$, we have $df(v_x) = v$, for all $v_x \in TM$,

\[
(Y_b f)(x) = Y_b(x) \quad \text{and} \quad (Y_a Y_b f)(x) = (\delta Y_a Y_b)(x),
\]

and so equation (4.11) becomes

\[
x_{s,t} = f(x_t) - f(x_s) \simeq (Y_{z_{s,t}} f)(x_s) = Y_{z_{s,t}}(x_s) + (\delta Y_a Y_b)(x_s)|_{\alpha \otimes b = Z_{s,t}}
\]

which is precisely equation (4.2). Similarly, equation (4.12) becomes

\[
[P_{x_s} \otimes P_{x_t}]X_{s,t} = (df \otimes df)([P_{x_s} \otimes P_{x_t}]X_{s,t}) \\
\simeq Y_a f(x_s) \otimes Y_b f(x_s)|_{\alpha \otimes b = Z_{s,t}} = Y_a(x_s) \otimes Y(x_s)|_{\alpha \otimes b = Z_{s,t}},
\]

which is equivalent to equation (4.3) by Corollary 3.22. \hfill \Box

**Remark 4.6.** If we restrict $W$ to be $\mathbb{R}$ in Theorem 4.5, then we may still conclude from either of items 2 or 3 of that theorem that $X$ satisfies equation (4.2), that is, the level one condition for the RDE solution (4.1). Indeed, if $f = \ell|_M : M \to \mathbb{R}$, where $\ell \in E^*$ is any linear functional on $E$, then

\[
(Y_a f)(x) = \ell Y_a(x) \quad \text{and} \quad (Y_a Y_b f)(x) = (Y_a \ell Y_b)(x) = \ell(\delta Y_a Y_b)(x).
\]

So, for $f = \ell|_M$, equation (4.11) becomes

\[
\ell(x_{s,t}) = f(x_t) - f(x_s) \simeq \ell Y_{z_{s,t}}(x_s) + \ell(\delta Y_a Y_b)(x_s)|_{\alpha \otimes b = Z_{s,t}}.
\]

As this true for all $\ell \in E^*$ we may conclude equation (4.2) holds.

**Remark 4.7.** We cannot get equation (4.3) from equation (4.10) without allowing for $\dim W > 1$. Indeed, if $\alpha \in \Omega^1(M, \mathbb{R})$, then

\[
\alpha \otimes \alpha \otimes \alpha\otimes \alpha_{x_s}([P_{x_s} \otimes P_{x_t}]X_{s,t}) \simeq \alpha_{x_s} \otimes \alpha_{x_s}[Y_a(x_s) \otimes Y_b(x_s)]|_{\alpha \otimes b = Z_{s,t}}
\]

from which we may only conclude that

\[
[P_{x_s} \otimes P_{x_t}]X_{s,t} \simeq [Y_a(x_s) \otimes Y_b(x_s)]|_{\alpha \otimes b = Z_{s,t}},
\]

(4.13)

This is because $\alpha \otimes (\xi \otimes \eta - \eta \otimes \xi) = (\alpha(\xi)\alpha(\eta) - \alpha(\eta)\alpha(\xi)) = 0$ since scalar multiplication is commutative. Here we have used that $\mathbb{R} \otimes_{\mathbb{R}} \mathbb{R} \cong \mathbb{R}$. The reader should further observe that
information contained in equation (4.13) is already a consequence of equation (4.2) and the assumption that \(\textbf{Z}\) and \(\textbf{X}\) are weakly geometric rough paths.

**Definition 4.8 (Intrinsic RDEs on manifolds).** Given a linear map \(Y : \mathbb{R}^n \to \Gamma(TM)\), we say that a geometric rough path \(\textbf{X} \in \mathcal{W}G_p(M)\) solves the RDE
\[
d\textbf{X}_t = Y_{\textbf{Z}_t}(x_t) \quad \text{with } x(0) = x_0 \in M
\]  
if and only if equations (4.11) and (4.12) hold for all \(f \in C^\infty(M,W)\) and every finite-dimensional vector space \(W\).

**Definition 4.9 (Intrinsic RDEs).** To emphasize when we are working with the intrinsic definition of an RDE, we sometimes write
\[
d\textbf{X}_t = Y_{\textbf{Z}_t}(x_t) \quad \text{with } x(0) = x_0 \in M
\]  
in place of (4.14) where now \(Z_{s,t} = z_{s,t} + Z_{s,t}\) and we interpret
\[
[Y_{\textbf{Z}}(x)]_{s,t}^2 \simeq [Y(x_s) \otimes Y(x_s)]Z_{s,t} \in \mathbb{R}^N \otimes \mathbb{R}^N.
\]

We end this subsection with a result describing (in special cases) the pushforward of solutions to RDEs.

**Definition 4.10.** Suppose that \(\pi : M \to N\) is a smooth map between two smooth manifolds. Also suppose that \(Y^M : \mathbb{R}^n \to \Gamma(TM)\) and \(Y^N : \mathbb{R}^n \to \Gamma(TN)\) are two linear maps. We say \(Y^M\) and \(Y^N\) are \(\pi\)-related dynamical systems if
\[
\pi_* Y^M_a = Y^N_a \circ \pi \quad \text{for all } a \in \mathbb{R}^n.
\]

**Theorem 4.11.** Suppose \(\pi : M \to N\) is a smooth map between manifolds. Let \(Y^M : \mathbb{R}^n \to \Gamma(TM)\) and \(Y^N : \mathbb{R}^n \to \Gamma(TN)\) be two \(\pi\)-related dynamical systems. Further, suppose that \(\textbf{Z} \in \mathcal{W}G_p(\mathbb{R}^n)\) and \(\textbf{X} = (x, \mathcal{X})\) solves the RDE
\[
d\textbf{X}_t = Y^M_{\textbf{Z}_t}(x_t) \quad \text{with } x_0 \in M \text{ given.}
\]
Then \(\textbf{X}^N := \pi_*(\textbf{X}) = (x^N, \mathcal{X}^N)\) solves the RDE,
\[
d\textbf{X}^N_t = Y^N_{\textbf{Z}_t}(x^N_t) \quad \text{with } x^N_0 := \pi(x_0) \in N \text{ given.}
\]

**Proof.** Fix a finite-dimensional vector space \(W\) and let \(f \in C^\infty(N,W)\). Applying item 3. of Theorem 4.5 to the function \(f \circ \pi \in C^\infty(M,W)\) shows
\[
f(x^N_t) - f(x^N_s) \simeq f \circ \pi(x_t) - f \circ \pi(x_s)
\]
\[
\simeq (Y^N_{\textbf{Z}^*_t}(f \circ \pi))(x_s) = (Y^N_{\textbf{Z}^*_t} f) \circ \pi(x_s) = (Y^N_{\textbf{Z}^*_t} f)(x^N_s)
\]
and
\[
X^N_{s,t} \simeq \pi_* \pi_* P(x_s) \otimes P(x_s) X_{s,t}
\]
\[
\simeq \pi_* \pi_* P(x_s) \otimes P(x_s) Y^M_{\gamma}(x_s) \otimes Y^M_{\gamma}(x_s) Z_{s,t}
\]
\[
= \pi_* Y^M_{\gamma}(x_s) \otimes \pi_* Y^M_{\gamma}(x_s) Z_{s,t}
\]
\[
= Y^N_{\gamma}(x^N_s) \otimes Y^N_{\gamma}(x^N_s) Z_{s,t}.
\]

4.2. **Fundamental properties of rough paths on manifolds**

Armed with well-defined notions of integration and RDEs, we now derive some of the fundamental properties of geometric and weakly geometric rough paths on manifolds. We also
exhibit some natural examples of elements in $WG_p(M)$ which are constructed by ‘projecting the increments’ of geometric rough paths on $E$ to the tangent space of $M$.

**Example 4.12 (Projection construction of geometric rough paths).** Let $Z$ be a weakly geometric $p$-rough path on $E$ for some $p \in [2,3)$; then there exists a unique rough path solution $X$ (possibly only up to an explosion time) to the RDE

$$dX_t = V_{dZ_t}(x_t) = P_{x_t}dZ_t \quad \text{with } x_0 \in M.$$  \hspace{1cm} (4.15)\]

Moreover, it will follow from Theorems 4.2 and 4.17 that $X \in G_{p'}(M) \cap WG_p(M)$ for all $p' > p$.

The following proposition shows that, in fact, all weakly geometric rough paths on $M$ may be constructed by this method.

**Proposition 4.13 (Consistency).** If $Z \in WG_p(M) \subset WG_p(E)$, then the unique solution to equation (4.15) with $x_0 = z_0$ is $X \equiv Z$. [So, in this setting the solution to equation (4.15) exists on all of $[0,T]$.]

**Proof.** The proof amounts to showing that $X = Z$ solves equation (4.15), that is, that

$$z_{s,t} = V_{z_{s,t}}(z_s) + (\partial V_b)(z_s)|_{a \otimes b = z_{s,t}} \quad \text{and} \quad Z_{s,t} = V_a(z_s) \otimes V_b(z_s)|_{a \otimes b = Z_{s,t}} = P(z_s) \otimes P(z_s)Z_{s,t}. \quad (4.16)$$

Equation (4.17) is a consequence of Corollary 3.20. The right-hand side of equation (4.16) is approximated as

$$P(z_s)z_{s,t} + dP([P(z_s)a]_{z_s})b|_{a \otimes b = Z_{s,t}} \simeq P(z_s)z_{s,t} + dP([P(z_s)a]_{z_s})P(z_s)b|_{a \otimes b = Z_{s,t}} \simeq P(z_s)z_{s,t} + Q(z_s)z_{s,t} = z_{s,t},$$

wherein we have used Lemma 3.28 for the second approximate equality above. \hfill \Box

We now address the relation between geometric and weakly geometric rough paths on manifolds. To do this we first require a couple of elementary lemmas.

**Lemma 4.14.** Suppose that $U$ is an open neighbourhood of $M$ and $\mathbb{R}^n \ni a \to \tilde{Y}_a \in \Gamma(TU)$ is a linear map such that $\tilde{Y}_a(m) \in T_m M$ for all $m \in M$. Further suppose that $z : [0,T] \to \mathbb{R}^n$ is a smooth function and $x : [0,T] \to U$ is a smooth solution to

$$\dot{x}(t) = \tilde{Y}_{\dot{z}(t)}(x(t)) \quad \text{with } x(0) = x_0 \in M.$$  \hspace{1cm} (4.18)\]

If there is an open neighbourhood, $\mathcal{V}$, in $E$ such that $x([0,T]) \subset \mathcal{V}$ and $\bigcap_{m \in M} M_E \subset M$, then $x(t) \in M$ for all $t \in [0,T]$ and $x(t)$ satisfies $\dot{x}(t) = Y_{\dot{z}(t)}(x(t))$ with $x(0) = x_0 \in M$.

**Proof.** By replacing $\mathcal{V}$ by $\mathcal{V} \cap U$, we may assume that $\mathcal{V} \subset U$. For the sake of contradiction, suppose that $x([0,T])$ is not contained in $M$ and let $\tau = \inf \{ t \in [0,T] : x(t) \notin M \}$ be the first exit time of $x(t)$ from $M$. Since $x(0) = x_0 \in M$ and $x(t) \in M$ for all $0 \leq t < \tau$ if $\tau > 0$, we may conclude that $x(\tau) \in \bigcap_{m \in M} M_E \subset M$. As $x([0,T])$ is not contained in $M$, we may now conclude that $\tau < T$.

By the local existence theorem for the ODEs, there exists an $\varepsilon > 0$ and a solution $y : [\tau, \tau + \varepsilon] \to M$ solving

$$\dot{y}(t) = Y_{\dot{z}(t)}(y(t)) \quad \text{with } y(\tau) = x(\tau).$$
The function $\tilde{x} : [0, \tau + \varepsilon] \to M$, defined by

$$\tilde{x}(t) := \begin{cases} x(t) & \text{if } 0 \leq t \leq \tau, \\ y(t) & \text{if } \tau \leq t \leq \tau + \varepsilon, \end{cases}$$

then solves equation (4.18) on $[0, \tau + \varepsilon]$ and hence, by uniqueness, $x(t) = \tilde{x}(t)$ for $0 \leq t \leq \tau + \varepsilon$. This, however, shows $x(t) \in M$ for $0 \leq t \leq \tau + \varepsilon$, which contradicts the definition of $\tau$.

**Lemma 4.15.** If $K$ is a compact subset of $M$, then there exists an open neighbourhood $\mathcal{V}$ in $E$ containing $K$ such that $\overline{M \cap \mathcal{V}}^E \subset M$.

**Proof.** First suppose $K = \{x\} \subset M$. Let $F : U \to \mathbb{R}^{N-d}$ be a local defining function for $M$ so that $x \in U$ and $U \cap M = \{F = 0\}$. Let $\mathcal{V}_x$ be a precompact open neighbourhood of $x$ in $E$ so that $\mathcal{V}_x \subset U$. Since $\overline{M \cap \mathcal{V}_x^E} \subset \overline{\mathcal{V}_x}^E \subset U$ and $F \equiv 0$ on $M \cap \mathcal{V}_x$, it follows by continuity that $F = 0$ on $\overline{M \cap \mathcal{V}_x^E}$ from which it follows that $\overline{M \cap \mathcal{V}_x^E} \subset \{F = 0\} \subset M$.

If $K$ is a general compact subset of $M$, to each $x \in K$ there exists a precompact open neighbourhood of $\mathcal{V}_x$ in $E$ with $x \in \mathcal{V}_x$ and $\overline{M \cap \mathcal{V}_x^E} \subset M$. Since $K$ is compact, there is a finite subset, $A \subset K$, such that $\mathcal{V} := \bigcup_{x \in A} \mathcal{V}_x$ contains $K$. This is the desired open set in $E$ since

$$\overline{M \cap \mathcal{V}^E} = \bigcup_{x \in A} \overline{M \cap \mathcal{V}_x^E} = \bigcup_{x \in A} \overline{M \cap \mathcal{V}_x^E} \subset M.$$  

**Lemma 4.16.** Let $\mathbb{R}^n \ni a \to Y_a \in \Gamma(TM)$ be a linear map, $Z \in G_p(\mathbb{R}^n)$, and suppose $z^k : [0, T] \to \mathbb{R}^n$ are smooth functions such that $S_2(z^k) \to Z$ in rough $p$-variation metric; see equation (A.1). Assume $X \in WG_p(M)$ satisfies the RDE $dX = Y_{aZ}(x)$ with starting point $x_0 = z_0$. Then, for $k$ sufficiently large, there exist smooth functions $x^k : [0, T] \to M$ (note: taking values in $M$) satisfying

$$\dot{x}^k(t) = Y_z^k(x(t)) \quad \text{with } x^k(0) = z_0,$$

and, moreover, such that $S_2(x^k)$ converges to $X$ in $WG_p(M)$. Consequently $X \in G_p(M)$.

**Proof.** By Remark 3.2 and a partition of unity argument we may find an open neighbourhood $U$ of $M$ in $E$ and a linear map $\mathbb{R}^n \ni a \to \hat{Y}_a \in \Gamma(TU)$ such that $\hat{Y}_a = Y_a$ on $M$. By Lemma 4.15, there exists a precompact open neighbourhood $\mathcal{V}$ in $E$ containing $K = \{x(0, T]\}$ such that $\overline{M \cap \mathcal{V}^E} \subset M$. By replacing $\mathcal{V}$ by $\mathcal{V} \cup U$, we may assume that $\mathcal{V} \subset U$. We can then find a linear map $\mathbb{R}^n \ni a \to \hat{Y}_a \in \Gamma(TU)$, such that $\hat{Y}_a = Y_a$ on $\mathcal{V}$ and the vector fields $\hat{Y}_a$ have compact support. As $x([0, T]) \subset \mathcal{V}$ and $X$ solves $dX = Y_{aZ}(x)$, it follows that $X$ also solves $dX = \hat{Y}_{aZ}(x)$. By Lemma 4.14, we know the equations $\dot{x}^k(t) = \hat{Y}_{z^k(t)}(x(t))$, $x^k(0) = z_0$ have (global) solutions $x^k(t) \in M$ for $0 \leq t \leq T$. In addition, it follows by the universal limit theorem [29, Theorem 5.3] that solutions to the differential equations

$$dX^k = \hat{Y}_{dS_2(z)}(x) \quad \text{with } x^k(0) = z_0$$

satisfy $S_2(x^k) \to X$ in $p$-variation as $k \to \infty$ and hence $x^k \to x$ uniformly. Therefore, for sufficiently large $k$, it follows that $x^k(t) \in \mathcal{V}$ for all $0 \leq t \leq T$ and hence $x^k(t) \in M$ (Lemma 4.14). Since $Y_a = \hat{Y}_a$ on $\mathcal{V} \cap \mathcal{M}$, we conclude that $x_k$ solve (4.19), as required.

**Theorem 4.17.** For all $p' > p \geq 1$, we have $G_p(M) \subseteq WG_p(M) \subseteq G_{p'}(M)$.

**Proof.** We have already demonstrated the first containment in Corollary 3.32. Suppose now $Z \in WG_p$; then in particular $Z \in WG_p(E)$ and hence by classical results (see [16, Corollary
8.24) $Z$ belongs to $G_p'(E)$. By Proposition 4.13, $Z$ solves the RDE,

$$dZ = V_{dZ}(z) = P(z)dZ, \quad \text{with } z_0 \in M.$$  \hspace{1cm} (4.20)

Consequently, by Lemma 4.16, $Z \in G_p(M)$. 

We conclude the section with the following theorem summarises three equivalent characterisations of weakly geometric rough paths on manifolds. We reemphasise that $WG_p(M)$ are precisely those rough paths in $WG_p(E)$ that consistently integrate finite-dimensional vector space-valued 1-forms $\alpha \in \Omega^1(M, W)$.

**Theorem 4.18** (Characterisation of $WG_p(M)$). If $Z \in WG_p(E)$, then the following are equivalent:

1. $Z \in WG_p(M)$.
2. The trace $z$ of $Z \in WG_p(E)$ is in $M$ and further satisfies, for all finite-dimensional vector spaces $W$,

$$\int \hat{\alpha}(dZ) = \int \hat{\alpha}(dZ)$$

for any $\hat{\alpha}, \tilde{\alpha} \in \Omega^1(E, W)$ such that $\hat{\alpha} = \alpha$ on $TM$;
3. The trace $z$ of $Z \in WG_p(E)$ is in $M$ and $Q_s, \otimes IZ_{st} \simeq 0$ for $0 \leq s \leq t \leq T$;
4. The starting point, $z_0$, is in $M$ and $Z$ solves the projection equation (4.15).

**Proof.** Lemma 3.23 shows that 1 implies 2 and taking $\hat{\alpha} = 0$ in item 2 shows $Z$ satisfies Definition 3.17 and so items 1 and 2 are equivalent. The equivalence of items 1 and 3 is the content of Proposition 3.35. The equivalence of items 1 and 4 follows from Example 4.12 and Proposition 4.13.

4.3. **Right invariant RDE’s on Lie groups**

To illustrate some of the results above, we are going to consider RDEs on a Lie group $G$ relative to right invariant vector fields. We assume, as is always possible, that $G$ is embedded in some Euclidean space $\mathbb{R}^N$. Although we will be using the results above we will not need to know any information about the embedding other than it exists.

**Definition 4.19.** To each Lie group $G$ with Lie algebra $\mathfrak{g} := \text{Lie}(G)$, let $Y^G : \mathfrak{g} \to \Gamma(TG)$ be the linear map defined by

$$(Y^G_\xi)(g) := -\dot{\xi}(g) := -\left.\frac{d}{dt}\right|_0 e^{t\xi}g,$$  \hspace{1cm} (4.21)

that is, $Y^G_\xi$ is the right invariant vector field on $G$ such that $Y^G_\xi(e) = -\xi$.

**Theorem 4.20** (Global solutions to right invariant RDEs). To each $A = (a, A) \in WG_p(\mathfrak{g}, \omega)$ there exists a (unique) global solution $G = (g, G)$ to the RDE

$$dG = \mathcal{Y}_{dA}^G(g) \quad \text{with } g_0 = e \in G.$$  \hspace{1cm} (4.22)

**Proof.** According to Theorem 4.2, equation (4.22) either has a solution on all of $[0, T]$ in which case we are done, or there is a $\tau \in (0, T]$ such that the solution $G$ exists on $[0, \tau)$ while $\{g_t : 0 \leq t < \tau\}$ is not compact. To finish the proof, we need only rule out the second case.

By Corollary 2.17, we may find and $\varepsilon > 0$ such that, for any $t_0 \in [0, T]$, there is a solution $H = (h, H)$ on $[t_0, \min(t_0 + \varepsilon, T)]$ to the RDE, $dH = \mathcal{Y}_{dA}^G(h)$ with $h_{t_0} = e \in G$. For $u \in G$, let $R_u : G \to G$ be the diffeomorphism of $G$ given by $R_u(x) = xu$ for all $x \in G$. By its very
definition, we have \( R_{u*}Y^\mu_{\xi} = Y^\mu_{\xi} \circ R_u \) and so, by an application of Theorem 4.11, it follows that \( K = (k, \xi) := (R_u)_*(\xi) \) solves \( dK = Y^0_{\xi}(k) \) with \( k_{t_0} = u \) on \([t_0, \min(t_0 + \epsilon, T)]\).

Choose \( t_0 \in (\max \{0, \tau - \epsilon/2\}, \tau) \) and apply the above result with \( u = g_{t_0} \) in order to produce a weakly geometric rough path, \( K = (k, \xi) \), on \([t_0, \min(\tau + \epsilon/2, T)]\) solving \( dK = Y^0_{\xi}(k) \) with \( k_{t_0} = g_{t_0} \). An application of Lemma A.2 (easily adapted to RDE on manifolds) shows that \( G \) restricted to \([0, t_0] \) and \( K \) on \([t_0, \min(\tau + \epsilon/2, T)]\) may be concatenated into a weakly geometric rough path \( \tilde{G} \) which solves equation (4.22) on \([0, \min(\tau + \epsilon/2, T)]\). This then violates the definition of \( \tau \) and shows that equation (4.22) cannot explode.

**Theorem 4.21 (Pushing forward solutions by Lie homomorphisms).** Suppose that \( \rho : G \to H \) is a Lie group homomorphism and for \( A = (a, \tilde{a}) \in WG_p(\mathfrak{g}, \omega) \) let

\[
A^\rho = (d\rho)_s(A) = ([dp]\alpha, [dp \otimes dp]\tilde{a}) \in WG_p(\mathfrak{h}, \omega).
\]

If \( G = (g, \mathbb{G}) \in WG_p(G) \) is the unique global solution to the RDE (4.22) and \( H = \rho_s(G) \), then

\[
dh = Y^0_{\rho_s h}(h) \quad \text{with} \quad h_0 = e_H \in H.
\]

Moreover, if \( \mathbb{G}^{T}_{s,t} := P^G(g_s) \otimes P^G(g_t)\mathbb{G}_{s,t} \) and \( \mathbb{H}^{T}_{s,t} := P^H(h_s) \otimes P^H(h_t)\mathbb{H}_{s,t} \) denote the tangential components of \( \mathbb{G} \) and \( \mathbb{H} \), respectively, then \( H \) may also be characterised by

\[
h_t = \rho(g_t) \quad \text{and} \quad \mathbb{H}^{T}_{s,t} \simeq [\rho_s \otimes \rho_s] \mathbb{G}^{T}_{s,t}.
\]

**Proof.** For \( \xi \in \mathfrak{g} \), let \( W_\xi \in \Gamma(TH) \) be defined by

\[
W_\xi(h) = Y^H_{\rho_s(\xi)}(h) = \frac{d}{dt} \bigg|_0 he^{-td\rho(\xi)}.
\]

A simple computation then shows that \( \rho_s Y^G_{\xi} = W_\xi \circ \rho \) and therefore by Theorem 4.11, \( H \in WG_p(H) \) satisfies the RDE

\[
dH = W_dA(h) \quad \text{with} \quad h_0 = \rho(e_G) = e_H \in H.
\]

Using \( W_{a,t} = Y^H_{d\rho(a)}(h) \) and

\[
W_a W_b|_{a \otimes b = A_{s,t}} = Y^H_{d\rho(a)} Y^H_{d\rho(b)}|_{a \otimes b = A_{s,t}} = Y^H_{\alpha \beta} Y^H_{\alpha \beta}|_{a \otimes b = d\rho(a) \otimes d\rho(b)}
\]

along with Theorem 4.5, one shows that \( H \) also solves equation (4.24). From Proposition 3.38, we know \( h_t = \rho(g_t) \) and from Equation 4.2 and Corollary 3.22,

\[
\mathbb{H}^{T}_{s,t} \simeq W_{(\cdot)}(h_s) \otimes W_{(\cdot)}(h_t)\mathbb{A}_{s,t} = [\rho_s Y^G_{(\cdot)}(g_s) \otimes \rho_s Y^G_{(\cdot)}(g_t)]\mathbb{A}_{s,t} \simeq [\rho_s \otimes \rho_s] \mathbb{G}^{T}_{s,t}.
\]

\[5. \ Parallel \ translation\]

In Subsection 5.1, we recall the definition of parallel translation along smooth curves in \( M \) along with some of its basic properties. In order to transfer these results to the rough path setting it is useful to introduce the orthogonal frame bundle \( (O(M)) \) over \( M \) which is done in Subsection 5.2. The ‘lifting’ of paths in \( M \) to ‘horizontal’ paths in \( O(M) \) and the relationship of these horizontal lifts to parallel translation is also reviewed here. After this warm-up, we defined parallel translation along \( X \in WG_p(M) \) as an element \( U \in WG_p(O(M)) \) solving a prescribed RDE on \( O(M) \) driven by \( X \); see Definition 5.13 of Subsection 5.3. An alternative characterisation of the level one components of \( U \) is then given in Proposition 5.15 which is then used to show that the RDE defining \( U \) exists on the full time interval, \([0, T]\). It is then shown in Theorems 5.16 and 5.17 that two natural classes of RDE’s on \( O(M) \) give rise to an element \( U \in WG_p(O(M)) \), each of which is parallel translation along \( X := \pi_*(U) \), where \( \pi : O(M) \to M \) is the natural projection map on \( O(M) \).
5.1. Smooth parallel translation

**Definition 5.1.** Given smooth paths \( x(t) \in M \) and \( v(t) \in E \) such that \( v(t)_{x(t)} \in T_{x(t)}M \) for all \( t \), the covariant derivative of \( v(\cdot)_{x(\cdot)} \) is defined as

\[
\frac{\nabla v(t)_{x(t)}}{dt} := [P(x(t))\dot{v}(t)]_{x(t)} = [\dot{v}(t) + dQ(\dot{x}(t))v(t)]_{x(t)},
\]

wherein the last equality follows by differentiating the identity, \( P(x(t))v(t) = v(t) \), and using \( dQ = -dP \). A path \( v(t)_{x(t)} \in TM \) is said to be parallel if \((\nabla/dt)[v(t)_{x(t)}] = 0\) for all \( t \), that is, \( v(t) \) solves the differential equation

\[
\dot{v}(t) + dQ(\dot{x}(t))v(t) = 0. \tag{5.1}
\]

If \( v(t) \) solves equation (5.1) with \( v(0) \in T_{x(0)}M \), then a simple calculation using equation (5.1) and Lemma 3.11 shows

\[
\frac{d}{dt} [Q(x(t))v(t)] = dQ(\dot{x}(t))[Q(x(t))v(t)] \quad \text{with} \quad Q(x(0))v(0) = 0
\]

which forces \( Q(x(t))v(t) = 0 \) by the uniqueness theorem of linear ordinary differential equations. Moreover, using \( PdQP = 0 \) (Lemma 3.11),

\[
\frac{d}{dt} \|v(t)\|_E^2 = 2 \langle v(t), \dot{v}(t) \rangle = -2 \langle v(t), dQ(\dot{x}(t))v(t) \rangle = -2 \langle P(x(t))v(t), dQ(\dot{x}(t))P(x(t))v(t) \rangle = 0,
\]

which shows \( \|v(t)\|_E = \|v(0)\|_E \).

**Notation 5.2.** Given two inner product spaces, \( V \) and \( W \), let \( \text{Iso}(V,W) \) denote the collection of isometries from \( V \) to \( W \).

From the previous discussion, if \( V \) is an inner product space and \( g_0 \in \text{Iso}(V,\tau_{x(0)}M) \), then the function \( g(t) \in \text{Hom}(V,E) \), solving

\[
\dot{g}(t) + dQ(\dot{x}(t))g(t) = 0 \quad \text{with} \quad g(0) = g_0, \tag{5.2}
\]

satisfies \( g(t) \in \text{Iso}(V,\tau_{x(t)}M) \) for \( 0 \leq t \leq T \).

**Definition 5.3** (Smooth parallel translation). Parallel translation along the smooth path \( x(\cdot) \in M \) is the collection of isometries, \( \parallel \cdot \parallel_x : T_{x(0)}M \to T_{x(t)}M \), defined by

\[
\parallel \cdot \parallel_x v_{x(0)} = [g(t)v]_{x(t)}, \tag{5.3}
\]

where \( g(t) \) solves equation (5.2) with \( g_0 = \text{Id}_{\tau_{x(0)}M} \in \text{Hom}(\tau_{x(0)}M,E) \).

5.2. The frame bundle, \( O(M) \)

**Definition 5.4.** The orthogonal frame bundle, \( O(M) \), is the subset of \( E \times \text{Hom}(\mathbb{R}^d,E) \) defined by,

\[
O(M) = \{(m,g) : m \in M \text{ and } g \in \text{Iso}(\mathbb{R}^d,\tau_mM)\}. \tag{5.4}
\]

Further, let \( \pi : O(M) \to M \) be the restriction to \( O(M) \) of projection of \( E \times \text{Hom}(\mathbb{R}^d,E) \) onto its first factor and set

\[
O_m(M) := \pi^{-1}\{m\} = \{m\} \times \text{Iso}(\mathbb{R}^d,\tau_mM). \tag{5.5}
\]

**Theorem 5.5** (Embedding the frame bundle). The orthogonal frame bundle, \( O(M) \), is an embedded submanifold of \( E \times \text{Hom}(\mathbb{R}^d,E) \). In fact, if \( F : U \to \mathbb{R}^{N-d} \) is a local defining
function for $M$, then
\[ G : U \times \text{Hom}(\mathbb{R}^d, E) \rightarrow \mathbb{R}^k \times \text{Hom}(\mathbb{R}^d, \mathbb{R}^k) \times S_d, \]
defined by
\[ G(x, g) := (F(x), Q(x)g, g^*g - I_d), \]
where $S_d$ denotes the linear subspace of $\text{End}(\mathbb{R}^d)$ consisting of symmetric $d \times d$ matrices, is a local defining function for $O(M)$. Moreover, if $(m, g) \in O(M)$, then
\[ T_{(m,g)}O(M) = \{(\xi, h)_{(m,g)} : \xi \in \tau_m M, Q(m)h = -dQ(\xi_m)g \text{ and } g^*h \in \text{so}(d)\}, \]
where $\text{so}(d)$ is the vector space of $d \times d$ real skew symmetric matrices.

The proof of this standard theorem is given in Appendix B for the readers convenience. From equation (5.7), if $(\xi, h)_{(m,g)} \in T_{(m,g)}O(M)$, then
\[ h = Q(m)h + P(m)h = -dQ(\xi_m)g + P(m)h \]
which leads to the decomposition of $T_{(m,g)}O(M)$ into its horizontal and vertical components,
\[ (\xi, h)_{(m,g)} = (\xi, -dQ(\xi_m)g)_{(m,g)} + (0, P(m)h)_{(m,g)}. \]  

**Definition 5.6.** The vertical sub-bundle, $T^vO(M)$, of $TO(M)$ is defined by
\[ T^v_{(m,g)}O(M) = \text{Null}(\pi_*(m,g)) = \{(0, h)_{(m,g)} : Q(m)h = 0 \text{ and } g^*h \in \text{so}(d)\}. \]
The horizontal sub-bundle, $T^\nabla O(M)$, associated to the Levi-Civita covariant derivative, $\nabla$, is defined by
\[ T^\nabla_{(m,g)}O(M) = \{(\xi, -dQ(\xi)m)_{(m,g)} : \xi \in \tau_m M\}. \]

According to equation (5.8),
\[ T_{(m,g)}O(M) = T^v_{(m,g)}O(M) \oplus T^\nabla_{(m,g)}O(M) \quad \text{for all } (m, g) \in O(M). \]

**Example 5.7 (Horizontal lifts).** A smooth path $u(t) = (x(t), g(t)) \in O(M)$ is horizontal if $\dot{u}(t) \in T^\nabla_{x(t)}O(M)$, which happens if and only if $g(t)$ solves equation (5.2). Given a smooth path, $x(\cdot)$, in $M$ and $(x(0), g_0) \in O_{x(0)}(M)$, there is a unique horizontal path $u(t) \in O(M)$ (called the horizontal lift of $x$) such that $u(0) = (x(0), g_0)$. The relationship of parallel translation to horizontal lifts is given by
\[ \frac{d}{dt}v_{x(t)} = [g(t)g_0^{-1}v]_{x(t)} \quad \text{for all } v \in \tau_{x(0)}M. \]

**Definition 5.8 (Horizontal lifts of vector fields).** If $W \in \Gamma(TM)$ and $u = (m, g) \in O(M)$, let
\[ W^\nabla(m, g) = (W(m), -dQ(W(m))g). \]  

We may also describe $W^\nabla$ by
\[ W^\nabla(u) := \left. \frac{d}{dt} \right|_{t=0} /_{t}(\sigma)u \quad \text{where } \dot{\sigma}(0) = W(\pi(u)) \]  

or alternatively as the unique horizontal vector field, $W^\nabla \in \Gamma(T^\nabla O(M))$, such that $\pi_*W^\nabla = W \circ \pi$. 
LEMMA 5.9. If $u(t)$ is the horizontal lift of a smooth path $x(\cdot)$ in $M$ starting at $(x(0), g_0)$, then $u(t)$ is the unique solution to the ordinary differential equation
\[\dot{u}(t) = V_{\dot{x}(t)}^\nabla(u(t)) \quad \text{with } u(0) = (x(0), g_0),\] (5.13)
where $V_z(m) = P(m)z$ for all $z \in E$ and $m \in M$ as in Example 3.7.

Proof. A path $u(t) = (x(t), g(t)) \in O(M)$ solves equation (5.13) if and only if
\[ (\dot{x}(t), \dot{g}(t))_{u(t)} = V_{\dot{x}(t)}^\nabla(u(t)) = (V_{\dot{x}(t)}(x(t)), -dQ(V_{\dot{x}(t)}(x(t)))g(t)) = (\dot{x}(t), -dQ(\dot{x}(t))g(t)), \]
that is, if and only if $g(t)$ solves equation (5.2).

To end this subsection, let us recall that the horizontal/vertical sub-bundle decomposition of $TO(M)$ in Definition 5.6 gives rise to two ‘canonical’ vector fields and 1-forms on $O(M)$.

DEFINITION 5.10. Let $u = (m, g) \in O(M)$. The canonical vertical vector field on $O(M)$ associated to $A \in so(d)$ is defined by
\[ V_A(u) := \left. \frac{d}{dt} \right|_0 u e^tA = (0, uA)_{(m, g)} \in T_u^\nabla O(M) \] (5.14)
while the horizontal vector field associated to $a \in \mathbb{R}^d$ (determined by $\nabla$) is defined by
\[ B_a(u) = B_a^\nabla(u) = (ga, -dQ(ga)g)_{(m, g)} \in T_u^\nabla O(M). \] (5.15)

DEFINITION 5.11. Let $u = (m, g) \in O(M)$. The canonical $\mathbb{R}^d$-valued 1-form, $\theta$, on $O(M)$ is defined by
\[ \theta((\xi, h)_{(m, g)}) := g^{-1}\xi = g^*\xi \quad \text{for all } (\xi, h)_{(m, g)} \in T_uO(M). \] (5.16)
The connection 1-form on $O(M)$ determined by the covariant derivative $\nabla$ is given by
\[ \omega^\nabla((\xi, h)_{(m, g)}) = g^{-1}[h + dQ(\xi_m)g] \in so(d), \] (5.17)
where $u(t) = (\sigma(t), g(t))$ is any smooth curve in $O(M)$ such that $\dot{u}(0) = (\xi, h)_{(m, g)}$.

REMARK 5.12. Since $g^{-1} = g^*$ and
\[ g^*dQ(\xi_m)g = g^*P(m)dQ(\xi_m)P(m)g = 0. \]
we may express $\omega^\nabla$ more simply as
\[ \omega^\nabla((\xi, h)_{(m, g)}) = g^*h. \] (5.18)
Also, if $u(t) := (x(t), g(t))$ is a smooth path in $O(M)$, then
\[ \frac{\nabla}{dt}[x(t), g(t)a] := (x(t), g(t)\omega^\nabla(\dot{u}(t))a) \quad \text{for all } a \in \mathbb{R}^d \]
from which it follows that $u(t)$ is horizontal if and only if $\frac{\nabla}{dt}[x(t), g(t)a] = 0$ for all $a \in \mathbb{R}^d$.

5.3. Rough parallel translation on $O(M)$
As in Proposition 3.12, we may choose to write $\Gamma$ for $dQ$. The following definition is motivated by Lemma 5.9.

DEFINITION 5.13 (Parallel translation on $M$). Given $X \in WG_p(M)$ and $u_0 \in O_{x_0}(M)$, we say $U \in WG_p(O(M))$ is parallel translation along $X$ starting at $u_0$ if $U$ solves the RDE
\[ dU = V_{dX}^\nabla(u) \quad \text{with } u(0) = u_0, \] (5.19)
where $V_z(x) := P_xz$ as in Example 3.7 and $V^\nabla$ is its horizontal lift as in Definition 5.8. [In Proposition 5.15, it will be shown that equation (5.19) has global solutions, that is, $U$ exists on $[0, T]$.]

**Lemma 5.14.** If $U$ is parallel translation along $X$ as in Definition 5.13, then $\pi_s(U) = X$.

**Proof.** From Definition 5.8, we know that $V^\nabla$ and $V$ are $\pi$-related dynamical systems and therefore, by Theorem 4.11, $\hat{X} := \pi_s(U)$ solves the RDE

$$d\hat{X} = V_\pi(\hat{x}) \quad \text{with} \quad \hat{x}_0 = \pi(u_0) = x_0.$$ 

On the other hand, by the consistence Proposition 4.13 we know that $X$ satisfies the same RDE and so by uniqueness of solutions to RDEs we conclude that $X = \hat{X} = \pi_s(U)$. \hfill \qed

**Proposition 5.15.** Suppose that $X \in WG_p(M)$, $A := \int \Gamma(dX)$, where $\Gamma := dQ$ and $U = (u = (x_t, g_t), \mathcal{U}) \in WG_p(O(M))$ is parallel translation along $X$ starting at $u_0 = (x_0, g_0)$. Then $g$ satisfies the level one component of the RDE

$$dg = (-dA)g. \quad (5.20)$$

In particular, the RDE in equation (5.19) exists for all time that $X$ is defined.

**Proof.** Using $dX = V_\pi(x)$ along with item 2. of Theorem 4.5 implies

$$a_{s,t} = \int \Gamma(dX) \quad \text{satisfies the same}\quad \text{RDE}\quad \text{as}$$

$$\hat{A}_{s,t} = \int \Gamma(dX) \quad \text{satisfies the same}\quad \text{RDE}\quad \text{as}$$

$$[A \otimes B] := BA. \text{Similarly, if we let} \ T(g) = g, \text{the RDE in equation (5.20) is equivalent to}$$

$$g_{s,t} = Y_{a_{s,t}}(\mathcal{T})(g_s) + (Y_{a_{s,t}}(\mathcal{T})(g_s))_{a \otimes b = \hat{X}_{s,t}} \quad \text{and}$$

From the theory of linear RDE [29] or by a minor modification of the results in Theorem 4.20 we know that $G$ solving equation (5.20) does not explode. Therefore, we may then conclude that $u_0 = (x_t, g_t)$ has no explosion. Combining this result with Lemma 2.18 then shows that the RDE of equation (5.19) also does not explode. \hfill \qed
\textbf{Theorem 5.16.} Let \( \mathbb{R}^n \ni z \rightarrow Y_z \in \Gamma(TM) \) be a linear map, \( Z \in W_p(\mathbb{R}^n) \) and \( u_0 \in O(M) \) be given. If \( X \in W_p(M) \) and \( U \in W_p(O(M)) \) solve the RDEs
\begin{align*}
dX &= Y_dZ(x) \quad \text{with } x_0 := \pi(u_0) \in M \quad \text{and} \\
dU &= Y_dV(u) \quad \text{with } u(0) = u_0, \tag{5.21}
\end{align*}
then \( U \) is a parallel translation along \( X \), that is, \( X = \pi_s(U) \) and \( U \) satisfies equation (5.19).

\textbf{Proof.} Since \( Y^V \) and \( Y \) are \( \pi \)-related, it follows from Theorem 4.11 that \( X = \pi_s(U) \). Using Theorem 4.5 and Remark 4.6, equation (5.22) at the first level is equivalent to
\[ F(u)_{s,t} \simeq (Y^V_{s,t} F)(u_s) + (Y^V_{s,t} F)(u_s) \]
while \( U \) solving equation (5.19) at the first level is equivalent to
\[ F(u)_{s,t} \simeq (V^V_{s,t} F)(u_s) + (V^V_{s,t} F)(u_s), \tag{5.24}
\]
where in each case \( F \) is assumed to be an arbitrary smooth function on \( O(M) \). Thus to complete the proof we must show that equation (5.23) implies equation (5.24) and show the second-order condition
\[ U_{s,t} \simeq [V^V(u_s) \otimes V^V(u_s)] X_{s,t}. \tag{5.25}
\]
First recall that
\begin{align*}
Y^V_z(x, g) &= (Y_z(x), -\Gamma(Y_z(x)) g) \quad \text{and} \\
V^V_z(x, g) &= (V_z(x), -\Gamma(V_z(x)) g) = (P(x) \xi, -\Gamma(P(x) \xi)) g
\end{align*}
so that \( Y^V_z = V^V_z \) from which (5.25) can be deduced immediately, and also
\[ Y^V_{\alpha \otimes \beta} F = Y^V_{\alpha} Y^V_{\beta} F = V^V_{\alpha} V^V_{\beta} F = V^V_{\alpha} V^V_{\beta} F|_{\beta = Y^V_{\beta}} + V^V_{Y^V_{\beta}} F. \]
Putting this together with equation (5.23) shows,
\[ F(u)_{s,t} \simeq dF(Y^V_{s,t}(x_s) + \nabla Y_{\alpha}(x_s) Y_{\alpha \otimes \beta} = Z_{s,t}) (u_s)) + (Y^V_{\alpha \otimes \beta} F)(u_s)|_{\alpha \otimes \beta = [Y^V_{\alpha}(x_s) \otimes Y^V_{\beta}(x_s)] Z_{s,t}}. \]
Thus to complete the proof, we must show
\[ x_{s,t} \simeq Y_{s,t}(x_s) + Y_{\alpha}(x_s) Y_{\alpha \otimes \beta} = Z_{s,t}. \tag{5.26}
\]
But we already know that \( X \) solves equation (5.21), which applied to the identity function \( I \) on \( \mathbb{R}^N \) shows
\begin{align*}
x_{s,t} &= I(x)_{s,t} \simeq (Y_{s,t} I)(x_s) + (Y_{\alpha} I)(x_s) Z_{s,t} \\
&= Y_{s,t}(x_s) + (Y_{\alpha} I)(x_s) Z_{s,t},
\end{align*}
which is precisely equation (5.26).
\[ \square \]

We will actually be more interested in the following variant of Theorem 5.16.

\textbf{Theorem 5.17.} Suppose that \( Z = (z, Z) \in W_p([0, T], \mathbb{R}^d, 0) \) and that \( U \in W_p(O(M)) \) solves
\[ dU = B_{\mathbb{R}^d}(u_t) \quad \text{with } u_0 = u_0 \text{ given}. \tag{5.27}
\]
Then \( U \) is a parallel translation along \( X = \pi_s(U) \), that is, \( U \) satisfies equation (5.19).

\textbf{Proof.} Working as above, equation (5.27) is equivalent to
\[ F(u)_{s,t} \simeq (B^V_{s,t} F)(u_s) + (B^V_{s,t} F)(u_s) \tag{5.28}
\]
while $\mathbf{U}$ solving equation (5.19) is equivalent to equation (5.24), where in each case $F$ is assumed to be an arbitrary smooth function on $O(M)$.

Thus to complete the proof, we must show that equation (5.28) implies equation (5.24) and the correspondence of the second-order pieces by the approximate identity

$$\mathbf{U}_{s,t} \simeq [\nabla V(u_s) \otimes \nabla V(u_s)]_{s,t}. \quad (5.29)$$

First recall that

$$B^\nabla_x(x, g) = ((gz)_x, -\Gamma((gz)_x)g) \quad \text{and} \quad V^\nabla_x(x, g) = (V_x(x), -\Gamma(V_x(x))g) = (P(x)\xi, -\Gamma(P(x)\xi))g$$

so that $B^\nabla_x(x, g) = V^\nabla_{gz}(x, g)$.

(5.29) is then immediate from the calculation

$$\mathbf{U}_{s,t} \simeq [B^\nabla_y(u_s) \otimes B^\nabla_y(u_s)]_{s,t} \simeq [\nabla V(u_s) \otimes \nabla V(u_s)]_{s,t}.$$

Furthermore, writing $u = (x, g)$, we have

$$(B_{a \otimes \beta}^\nabla F)(u) = (B^\nabla_{a \otimes \beta} F)(u) = B^\nabla_{a \otimes \beta} [(x, g) \rightarrow (V^\nabla_{gb} F)(x, g)]$$

and putting this together with equation (5.28) shows

$$F(u)_{s,t} \simeq dF(V^\nabla_{gsz, s,t} - \Gamma((ga)_{s,t})gb|_{a \otimes \beta = s,t}(u_s)) + (V^\nabla_{a \otimes \beta} F)(u_s)|_{a \otimes \beta = s,t} \simeq [\nabla V(u_s) \otimes \nabla V(u_s)]_{s,t}. \quad (5.30)$$

Applying equation (5.28) to $F = \pi$, where $\pi(x, g) = x$, shows

$$x_{s,t} = [\pi]_{s,t} \simeq (B^\nabla_{gsz, s,t} - \Gamma((ga)_{s,t})gb|_{a \otimes \beta = s,t}(u_s) + (B^\nabla_{gsz, s,t} \pi)(u_s). \quad (5.31)$$

Using

$$(B_b \pi)(x, g) = gb \quad \text{and} \quad (B_a B_b \pi)(x, g) = -\Gamma((ga)_{x})gb,$$

in equation (5.31) gives

$$x_{s,t} \simeq gs_{s,t} - \Gamma((ga)_{s,t})gb|_{a \otimes \beta = s,t} \quad (5.32)$$

which combined with equation (5.30) shows that equation (5.24) does indeed hold.

$$\square$$

6. Rolling and unrolling

In this section, we develop the rough path analogy of Cartan’s rolling map. As a consequence we will see that rough paths on a $d$-dimensional manifold are in one-to-one correspondence with rough paths on $d$-dimensional Euclidean space.

Definition 6.1. A manifold $M$ is said to parallelizable if there exists a linear map, $Y : \mathbb{R}^d \rightarrow \Gamma(TM)$ such that the map

$$Y(m) : a \mapsto Y_a(m) \in T_m M$$

is a linear isomorphism for all $m \in M$. We refer to any choice of $Y : \mathbb{R}^d \rightarrow \Gamma(TM)$ with this property as a parallelism of $M$. Associated to a parallelism $Y$ is an $\mathbb{R}^d$-valued 1-form on $M$ given by

$$\theta^Y(v_m) := Y(m)^{-1}v.$$

It is easy to see that every vector space is parallelizable; we detail some other not so trivial examples which will be useful later.
Example 6.2. Every Lie group $G$ is parallelizable. Indeed, if we let $d = \dim G$, so that the Lie algebra $\mathfrak{g} := \text{Lie}(G) \cong \mathbb{R}^d$, then $Y = Y^G$ of equation (4.21) defines a parallelism on $G$. In this case, the associated 1-form $\theta^Y$ is known as the (right) Maurer–Cartan form on $G$.

Example 6.3. Let $M = M^d$ be any Riemannian manifold and $O(M)$ be the associated orthogonal frame bundle. Then $O(M)$ is parallelizable with $T_oO(M) \cong \mathbb{R}^d \times \text{so}(d)$. In this case, we can define a parallelism by taking

$$Y^{O(M)}(u)(a, A) := B_a(u) + V_A(u),$$

(6.1)

where $B_a$ and $V_A$ were defined in equations (5.14) and (5.15). In this case, the associated $\mathbb{R}^d \times \text{so}(d)$-valued 1-form $\theta^{Y^{O(M)}} := (\theta, \omega)$ on $O(M)$ is determined by

$$(\theta, \omega)(B_a(u) + V_A(u)) := (a, A) \quad \text{for all } (a, A) \in \mathbb{R}^d \times \text{so}(d) \quad \text{and } u \in O(M),$$

(6.2)

where $\theta$ and $\omega$ are as in Definition 5.11.

6.1. Smooth rolling and unrolling

The following ‘rolling and unrolling’ theorems in the smooth category are all relatively easy to prove and therefore most proofs are omitted here. They are included as a warm-up to the more difficult rough path versions which appear in the next subsection.

Theorem 6.4 (Rolling and unrolling I). Let $M$ be a parallelizable manifold and $Y : \mathbb{R}^d \to \Gamma(TM)$ be a parallelism and $\theta^Y$ be the associated 1-form. Fix $o \in M$. Then every $x \in C^1_o([0, T], M)$ determines a path in $z \in C^1_o([0, T], \mathbb{R}^d)$ by

$$C^1_o([0, T], M) \ni x \longrightarrow z := \int_0^1 \theta^Y(dx_s) = \int_0^1 Y(x_s)^{-1} \dot{x}_s \../ds.$$  

(6.3)

Conversely, given $z \in C^1_o([0, T], \mathbb{R}^d)$, the solution to the differential equation

$$\dot{x}_t = Y(x_t)\dot{z}_t \quad \text{with } x_0 = o \in M,$$

(6.4)

which may explode in finite time $\tau = \tau(z) < T$, is such that $x \in C^1_o([0, \tau], M)$ and over $[0, \tau)$

$$z = \int_0^{\tau} \theta^Y(dx_s).$$

(6.5)

The solution to (6.4) determines the inverse of the map (6.3); that is, the solution to (6.4) satisfies (6.5) and any $x \in C^1_o([0, \tau], M)$ agrees with the solution $w$ to the differential equation

$$\dot{w}_t = Y(w_t)\dot{z}_t \quad \text{with } x_0 = o \in M,$$

until the explosion time of this equation.

Corollary 6.5. Fix $o \in M$ and $u_o$ an orthogonal frame at $o$. Then every $u \in C^1_{u_o}([0, T], O(M))$ determines an element of $C^1_{(0,0)}([0, T], \mathbb{R}^d \times \text{so}(d))$ by the map

$$C^1_{u_o}([0, T], O(M)) \ni u \longrightarrow \int_0^1 \theta^{Y^{O(M)}}(du) = \int_0^1 \theta(du) + \int_0^1 \omega(du) \in C^1_{(0,0)}([0, T], \mathbb{R}^d \times \text{so}(d)).$$

(6.6)

Suppose that $(a, A) \in C^1_{(0,0)}([0, T], \mathbb{R}^d \times \text{so}(d))$ and define $u$ to be the solution to the differential equation

$$\dot{u}_t = B_{a_t}(u_t) + V_{A_t}(u_t) \quad \text{with } u_0 = u_o \text{ given},$$

(6.7)
which may explode in finite time \( \tau := \tau(a, A) < T \). Then \( u \) is in \( C^1_{u_o}([0, T], O(M)) \), and over \([0, \tau)\) we have
\[
\int_0^\tau (\theta, \omega)(du) = (a, \omega).
\] (6.8)

**Theorem 6.6.** The solution to (6.7) determines the inverse to (6.6) until explosion; that is, the solution to (6.7) satisfies (6.8), and any \( u \in C^1_{u_o}([0, T], O(M)) \) agrees with \( w \), the solution to the differential equation
\[
\dot{w}_t = B_{\theta(\hat{u}_t)}(w_t) + V_{\omega(\hat{u}_t)}(w_t) \quad \text{with } w_0 = u_o \in O(M),
\]
until the explosion time of this equation.

**Definition 6.7.** We say a path \( u \in C^1([0, T], O(M)) \) is horizontal (or parallel) provided \( \omega(\hat{u}_t) = 0 \), that is, provided \( \int_0^\tau \omega(du) \equiv 0 \). We let \( H^1([0, T], O(M)) \) denote the horizontal path in \( C^1([0, T], O(M)) \).

**Theorem 6.8.** Let \( u \in C^1([0, T], O(M)) \) and \( x := \pi(u) \in C^1([0, T], M) \) be its projection to \( M \). Then \( u \) is horizontal if and only if \( u_t = /_{/t}(x)u_0 \) for all \( 0 \leq t \leq T \).

**Proof.** If \( u \in C^1([0, T], O(M)) \), then we have from equation (5.17) that \( \omega(\hat{u}_t) = u_t^{-1}(\nabla u_t/\dot{t}) \), which is zero if and only if \( \nabla u_t/\dot{t} = 0 \) if and only if \( u_t = /_{/t}(x)u_0 \) for all \( 0 \leq t \leq T \). \( \square \)

**Corollary 6.9.** Let \( M \) be a Riemannian manifold with \( o \in M \) and \( u_o \in O(M) \) given. Then the map
\[
H^1_{u_o}([0, T], O(M)) \ni u \longrightarrow \pi \circ u \in C^1_o([0, T], M)
\] (6.9)
is a bijection with inverse map given by
\[
C^1_o([0, T], M) \ni x \longrightarrow u_t := /_{/t}(x)u_o \in H^1_{u_o}([0, T], O(M)).
\] (6.10)

**Corollary 6.10.** Let \( M \) be a Riemannian manifold with \( o \in M \) given. Then there exists a one-to-one correspondence between \( C^1_o([0, T], M) \) and \( C^1_0([0, T], \mathbb{R}^d) \) determined by,
\[
C^1_o([0, T], M) \longrightarrow H^1_{u_o}([0, T], O(M)) \longrightarrow C^1_0([0, T], \mathbb{R}^d)
\]
\[
x \longrightarrow /_{/t}(x)u_o \longrightarrow \int_0^x \theta(d[//_{/s}(x)u_o]) = u_o^{-1} \int_0^x /_{/s}(x)^{-1} dx_s.
\]

6.2. Rough rolling and unrolling

**Theorem 6.11** (Rough rolling and unrolling I). Let \( M \) be a parallelizable manifold and \( Y : \mathbb{R}^d \to \Gamma(TM) \) be a parallelism and \( \theta^Y \) be the associated one form. Fix \( o \in M \). Then every \( X \in W_{G_p}([0, T], M, o) \) determines an element of \( W_{G_p}([0, T], \mathbb{R}^d, 0) \) by the map
\[
W_{G_p}([0, T], M, o) \ni X \longrightarrow Z := \int_0^x \theta^Y(dX) \in W_{G_p}([0, T], \mathbb{R}^d, 0).
\] (6.11)
Suppose that \( Z = (z, \Omega) \in W_{G_p}([0, T], \mathbb{R}^d, 0) \) and let \( X \) denote the solution to the RDE
\[
dX = Y dZ, (x_t) \quad \text{with } x_0 = o \in M,
\] (6.12)
with possible explosion time \( \tau := \tau(Y, Z) < T \). Then \( X \) is in \( WG_p([0, \tau), M, o) \) and over \([0, \tau)\) we have
\[
\int_0^\tau \theta^Y(dX) = Z. \tag{6.13}
\]

The solution to (6.12) determines the inverse to (6.11) until explosion; that is, both (6.13) holds and any \( X \in WG_p(M, o) \) agrees with \( W \) the solution to the RDE
\[
dW_t = Y(w_t) d\left[ \int_0^t \theta^Y(dX) \right] \quad \text{with } w_0 = o \in M \tag{6.14}
\]
until the explosion time of this equation.

Proof. Suppose that \( Z \in WG_p(\mathbb{R}^d, 0) \) and let \( X \) solve equation (6.12). Since \( \theta^Y(Y_a) = a \) for all \( a \in \mathbb{R}^d \), it follows that \( Y_a[\theta^Y(Y_b)] = Y_a[b] = 0 \) and hence from item 2 of Theorem 4.5
\[
\int_0^1 \theta^Y(dX) \simeq \theta^Y(x, Y_s, t) \equiv z_{s,t}
\]
and
\[
\int_0^2 \theta^Y(dX) \simeq [\theta_x Y(x, t) \otimes \theta_x Y(x, t)] Z_{s,t} = Z_{s,t}.\]

Conversely, suppose that \( X \in WG_p(M, o) \) and now define \( Z = (z, Z) \) by \( Z = \int_0^t \theta^Y(dX) \). We need to show, making the usual caveat about explosion, that \( X \) is the solution to (6.14). To this end, we first note
\[
Z_{s,t} \simeq [\theta_x \otimes \theta_x] [P_{x_s} \otimes P_{x_t}] X_{s,t}
\]
and
\[
z_{s,t} \simeq \theta_x P_{x_s, x_t} + \nabla\theta[P_{x_s} \otimes P_{x_t}] X_{s,t}.
\]
Since \( Y \theta = Id_{TM} \), it follows from the last two equations that
\[
Y(x) \otimes Y(x) Z_{s,t} \simeq Y(x) \otimes Y(x) [\theta_x \otimes \theta_x] [P_{x_s} \otimes P_{x_t}] X_{s,t}
\]
and
\[
Y(x) z_{s,t} \simeq P_{x_s, x_t} + Y(x) \nabla\theta[P_{x_s} \otimes P_{x_t}] X_{s,t} \simeq P_{x_s, x_t} + Y(x) \nabla\theta[Y(x) \otimes Y(x) Z_{s,t}]
\]
or, equivalently, that
\[
X_{s,t} \simeq [P_{x_s} \otimes P_{x_t}] X_{s,t} \simeq Y(x) \otimes Y(x) Z_{s,t} \tag{6.15}
\]
and
\[
P_{x_s, x_t} \simeq Y(x) z_{s,t} - Y(x) \nabla\theta[Y(x) \otimes Y(x) Z_{s,t}]. \tag{6.16}
\]
Again, using the fact that \( Y \theta = Id_{TM} \), we see that
\[
0 = \nabla Id_{TM} = \nabla[Y \theta] = (\nabla Y) \theta + Y \nabla \theta,
\]
which combined with equation (6.16) and the fact that \( \theta Y_a = a \) for all \( a \in \mathbb{R}^d \) implies
\[
P_{x_s, x_t} \simeq Y(x) z_{s,t} + (\nabla Y(\cdot) \theta(\cdot)) [Y(x) \otimes Y(x) Z_{s,t}]
\]
\[
= Y(x) z_{s,t} + (\nabla Y(\cdot) Y(\cdot)) Z_{s,t}
\]
\[
= Y_{z_s, t}(x_s) + P_{x_s}(\partial Y_a Y_b)(x_s)|_{a \otimes b = Z_{s,t}}. \tag{6.17}
\]
We can specialise this result to $O$ identity paths as equation (4.3) and these equations are equivalent to the following.

It only remains to show which may explode in finite time $U \in \mathcal{W}$. Since adding equations (6.17) and (6.18) gives equation (4.2) while equation (6.15) is the same as equation (4.3) and these equations are equivalent to $X \in \mathcal{W}G_p(M, o)$ solving equation (6.12). However, from equation (3.15) of Lemma 3.28,

$$Q_{x,s,t} \simeq Q_{x,s}(\partial p_{x,s}(P)X_{s,t} \simeq Q_{x,s}(\partial p_{x,s}(P))[Y(x) \otimes Y(x)]Z_{s,t}.$$ This gives equation (6.18) since $Q(\partial Y)P = Q \partial Y$, which is proved by applying $Q$ to the identity

$$\partial Y = \partial [PY] = (\partial Y)P + P \partial Y.$$

6.3. Rolling via the frame bundle

We can specialise this result to $O(M)$. Making use of the notation in Example 6.3, we obtain the following.

**Corollary 6.12.** Fix $o \in M$ and $u_0$ an orthogonal frame at $o$. Then every $U \in \mathcal{W}G_p([0, T], O(M), u_o)$ determines an element of $\mathcal{W}G_p([0, T], \mathbb{R}^d \times so(d), (0, 0))$ by the map

$$\mathcal{W}G_p([0, T], O(M), u_o) \longrightarrow \mathcal{W}G_p([0, T], \mathbb{R}^d \times so(d), (0, 0))$$

$$U \longmapsto \int_0^1 \theta^{Y^{O(M)}}(dU_t) := \int_0^1 (\theta, \omega)(dU_t).$$

Suppose that $Z \in \mathcal{W}G_p(\mathbb{R}^d \times so(d), (0, 0))$, and let $a, A$ denote the projections of $Z$ to the elements of $\mathcal{W}G_p(\mathbb{R}^d, 0)$ and $\mathcal{W}G_p(so(d), 0)$, respectively. Define $U$ to be the solution to the RDE

$$dU = Y^{O(M)}(u) \text{ with } u_0 = u_o \text{ given},$$

which may explode in finite time $\tau := \tau(Z) < T$. Then $U$ is in $\mathcal{W}G_p([0, \tau], O(M), u_o)$ and over $[0, \tau)$ we have

$$\int_0^{\tau} \theta^{Y^{O(M)}}(dU) = Z.$$ 

**Theorem 6.13.** The solution to (6.20) determines the inverse to the map (6.19) until explosion; that is, the solution to (6.20) satisfies (6.21), and any $U \in \mathcal{W}G_p(O(M), u_o)$ agrees with $W$, the solution to the RDE

$$dW = Y^{O(M)}(w_0)d\left[\int_0^t \theta^{Y^{O(M)}}(dU_s)\right] \text{ with } w_0 = u_o \in O(M),$$

until the explosion time of this equation.

**Definition 6.14.** We say a rough path $U \in \mathcal{W}G_p([0, T], O(M), u_o)$ is horizontal provided

$$\left(\theta, \omega\right)(dU_t) = \int_0^t \theta^{Y^{O(M)}}(dU) \in \mathcal{W}G_p([0, T], \mathbb{R}^d \times \{0_{so(d)}\}, (0, 0)),$$

where $\omega$ is the connection 1-form defined in (5.17) and $\theta$ is the canonical 1-form on $O(M)$ defined in equation (5.16). We use $\mathcal{H}\mathcal{W}G_p([0, T], O(M), u_o)$ to denote the horizontal rough paths $\mathcal{W}G_p([0, T], O(M), u_o)$. 
and it is not enough to assume $R$ components in $\omega$.

From these identities and item 2 of Theorem 4.5, we conclude

$$\int (\theta, \omega)(dU) = \int (\theta, 0)(dU),$$

where $0 \in \Omega^1(O(M), so(d))$ is the identically zero 1-form on $O(M)$ with values in $so(d)$. Consequently $U \in W G_p([0, T], O(M), u_o)$ is horizontal implies $\int \omega(dU) = 0$. On the other hand, it is not enough to assume $\int \omega(dU) = 0$ in order to conclude $U$ is horizontal because the condition $\int \omega(dU) = 0$ does not rule out $[\int (\theta, \omega)(dU)]^2$ having cross-term components, that is, components in $\mathbb{R}^d \otimes so(d) \oplus so(d) \otimes \mathbb{R}^d$.

**Remark 6.15.** Another way to state equation (6.22) is that $U \in W G_p([0, T], O(M), u_o)$ is horizontal provided

$$\int (\theta, \omega)(dU) = \int (\theta, 0)(dU),$$

where $0 \in \Omega^1(O(M), so(d))$ is the identically zero 1-form on $O(M)$ with values in $so(d)$. Consequently $U \in W G_p([0, T], O(M), u_o)$ is horizontal implies $\int \omega(dU) = 0$. On the other hand, it is not enough to assume $\int \omega(dU) = 0$ in order to conclude $U$ is horizontal because the condition $\int \omega(dU) = 0$ does not rule out $[\int (\theta, \omega)(dU)]^2$ having cross-term components, that is, components in $\mathbb{R}^d \otimes so(d) \oplus so(d) \otimes \mathbb{R}^d$.

**Proposition 6.16 (Parallel implies horizontal).** If $U \in W G_p([0, T], O(M), u_o)$ is parallel translation along $X := \pi_*(U) \in W G_p(M, o)$, then $U$ is horizontal.

**Proof.** Recall $\Gamma = \partial_t M$ and that $U$ solves (see Definition 5.13) $dU = V_d^\nabla(U)$, where $V_a^\nabla(m, g) = (V_a(m), -\Gamma(V_a(m))g)$ and $V_a(m) = P_m a$ for all $a \in E$. Using these formulas, we find, for $u = (m, g) \in O(M)$ and $a, b \in E$, that

$$\theta^{Yo(M)}(V_b^\nabla(u)) = (\theta, \omega)(V_b^\nabla(u)) = (g^*V_b(m), 0)$$

and

$$V_a^\nabla(u)(\theta^{Yo(M)}(V_b^\nabla)) = V_a^\nabla(u)(x, h) \rightarrow (h^*V_b(x), 0)) = (g^*(\partial_h V_a(b))(m) - g^*\Gamma(V_a(m))V_b(m), 0) = (\theta^*V_a(m)V_b, 0),$$

wherein in the last line we have used $Pg = g$ so that $g^* = g^*P$ and hence

$$g^*\Gamma(V_a(m))V_b(m) = g^*P_m dQ(V_a(m))P_m V_b(m) = 0.$$

From these identities and item 2 of Theorem 4.5, we conclude

$$\left[\int \theta^{Yo(M)}(dU)\right]_{s,t}^{1} \simeq (g_s^*V_a(x_s), 0) + (g_s^*\nabla V_a(x_s)V_b, 0)_{a \oplus b = X_{s,t}}$$

and

$$\left[\int \theta^{Yo(M)}(dU)\right]_{s,t}^{2} \simeq \theta^{Yo(M)}(V_a^\nabla(u_s)) \otimes \theta^{Yo(M)}(V_b^\nabla(u_s))_{a \oplus b = X_{s,t}}$$

$$= (g_s^*V_a(x_s), 0) \otimes (g_s^*V_b(x_s), 0)_{a \oplus b = X_{s,t}}$$

from which it follows that

$$\int \theta^{Yo(M)}(dU) \in W G_p([0, T], \mathbb{R}^d \times \{0_{so(d)}\}, (0, 0)).$$

**Theorem 6.17.** Let $U \in W G_p([0, T], O(M), u_o)$ and $X := \pi_*(U) \in W G_p(M, o)$ be its pushforward under the projection $\pi: O(M) \rightarrow M$. Then the following are equivalent:

1. $U$ is horizontal;
2. there exist $a \in W G_p([0, T], \mathbb{R}^d, 0)$ such that
   $$dU = B_{\text{dh}}(u_t) \quad \text{with} \quad u_0 = u_o \quad \text{given};$$
3. $U$ is parallel translation along $X$ starting at $u_0$.

\[\square\]
Proof. From Theorem 5.17, we know 2 \implies 3 and from Proposition 6.16 we know 3 \implies 1. So to finish the proof, it suffices to show 1 \implies 2. For the proof of this assertion let

\[ Z := \int \theta^{O(M)}(dU) \in WG_p([0, T], \mathbb{R}^d \times \text{so}(d), (0, 0)) \]

and

\[ a := (a, a) = \left( P_{\mathbb{R}^d}dZ, P_{\mathbb{R}^d} \otimes P_{\mathbb{R}^d}dZ_{st} \right), \]

where \( P_{\mathbb{R}^d} : \mathbb{R}^d \times \text{so}(d) \rightarrow \mathbb{R}^d \) is the linear projection onto the first factor.

(1 \implies 2) By definition \( U \) is horizontal if and only if \( Z := \int \theta^{O(M)}(dU) \in WG_p([0, T], \mathbb{R}^d \times \{0\}, (0, 0)) \). Corollary 6.12 then asserts that

\[ dU = \mathcal{J}^{O(M)}(u_t) \quad \text{with} \quad u_0 = u_o. \]

As \( Z \in WG_p([0, T], \mathbb{R}^d \times \{0\}, (0, 0)) \), one easily verifies that \( \mathcal{J}^{O(M)} = B_{a,t} \) from which it follows that the previously displayed RDE is equivalent to the RDE in equation (6.23).

**Theorem 6.18.** Let \( M \) be a Riemannian manifold with \( o \in M \) and \( u_o \in O_o(M) \) given. Then the map

\[ \mathcal{H}WG_p([0, T], O(M), u_o) \ni U \longrightarrow \pi_*(U) \in WG_p([0, T], M, o) \quad (6.24) \]

is a bijection with inverse map given by

\[ WG_p([0, T], M, o) \ni X \longrightarrow \mathcal{H}u_0 \in \mathcal{H}WG_p([0, T], O(M), u_o), \quad (6.25) \]

where \( \mathcal{H}u_0 := U \) is parallel translation along \( X \) starting at \( u_0 \) as in Definition 5.13 and Proposition 5.15.

**Corollary 6.19.** Let \( M \) be a Riemannian manifold with \( o \in M \) given. Then there exists a one-to-one correspondence between \( WG_p([0, T], M, o) \) and \( WG_p(\mathbb{R}^d, 0) \) determined for any choice of initial frame \( u_o \in O_o(M) \) by

\[ WG_p([0, T], M, o) \longrightarrow \mathcal{H}WG_p([0, T], O(M), u_o) \longrightarrow WG_p(\mathbb{R}^d, 0) \]

\[ X \longrightarrow U = \mathcal{H}u_0 \longrightarrow \int_0^1 \theta(d\mathcal{H}u_o), \quad (6.26) \]

where \( \theta \) is the canonical 1-form.

**Appendix A. Some additional rough path results**

In this section, we gather some additional results and notation of the theory of rough paths on Banach spaces. The literature on Banach space-valued rough paths is now so well-established as to be classical; the reader seeking more background has a great many choices: [14, 16, 18, 22, 28, 29]. As in Section 2, let \( V, W \), and \( U \) denote Banach spaces. In addition, we assume \( p \in [2, 3) \) is a fixed number and \( \omega \) is a control in the sense of Definition 2.3. Recall the definition of a \( p \)-rough path and \( R_p(V) \), the set of \( p \)-rough paths on \( V \) from Definition 2.4.

We can define a metric on \( R_p(V) \) by setting

\[ \rho_p,\omega(X, Y) := \sup_{0 \leq s < t \leq T} \frac{|x_{s,t} - y_{s,t}|}{\omega(s, t)^{1/p}} + \sup_{0 \leq s < t \leq T} \frac{|x_{s,t} - Y_{s,t}|}{\omega(s, t)^{2/p}} \quad (A.1) \]

for \( X = (x, X) \), \( Y = (y, Y) \in R_p(V) \). Note that endowed with this metric \( R_p(V) \) is a complete metric space.
A.1. Concatenation of local rough paths on $M$

Localisation plays an important role in the manifold setting, and we need results which will allow us to glue together locally constructed rough paths on $M$. The following elementary lemma (compare [5]) allows us to concatenate a finite number of rough paths.

**Lemma A.1** (Concatenating rough paths). Suppose that $\Pi = \{0 = t_0 < t_1 < \cdots < t_n = T\}$ is a partition of $[0, T]$. For $k \in \{1, \ldots, n\}$, let $J_k := [t_{k-1}, t_k]$, and, for each $k$, assume that we are given $X(k) \in WG_p(J_k, W)$. Then there exists a unique $X \in WG_p([0, T], W)$ such that $x(0) = 0$ and for all $1 \leq k \leq n$,

$$X(k)_{s,t} = X_{s,t} \quad \text{for all } s, t \in J_k.$$  \hfill (A.2)

**Proof.** Let $x(0) = 0$. For $0 \leq s \leq t \leq T$ with $s \in J_k$ and $t \in J_\ell$, we define

$$X_{s,t} := X(k)_{s,t_k} X(k+1)_{t_k, t_{k+1}} \cdots X(\ell)_{t_{\ell-1}, t},$$  \hfill (A.3)

where we now view $X(k)_{u,v} \in \mathbb{R} \otimes \cdots \otimes W \otimes W$ and the multiplication is the usual multiplication in the truncated tensor algebra (see, for example, [29]). We now need to check that $X \in WG_p([0, T], W)$.

The multiplicative property of rough paths follows directly from equation (A.3). The weakly geometric property can either be verified by direct calculation or one just observes that a rough path is weakly geometric if and only if it has finite $p$-variation and takes values in the free nilpotent group of step $[p]$ (see, for example, [29, p. 53]). We finally check that $X$ satisfies the correct variation conditions. To this end, observe that if $\omega$ is a control so that

$$|x_{u,v}| = |x_{u,v}(k)| \leq \omega(u,v)^{1/p} \quad \text{and} \quad |X_{u,v}^\omega| \leq \omega(u,v)^{2/p} \quad \text{for } u,v \in J_k, \quad 1 \leq k \leq n,$$

a straightforward calculation shows that there exists a constant $C_{p,n}$ such that $C_{p,n}\omega(s,t)$ controls the concatenated path. \hfill \Box

The following lemma allows us to compose the flows of RDEs.

**Lemma A.2** (RDE concatenation lemma). Let $\tau \in [0, T]$, $Z \in WG_p(W, [0, T])$ and $Y : V \rightarrow \text{Hom}(W, V)$ be a smooth map. Suppose $\tilde{X} \in WG_p(V)$ solves

$$d\tilde{X}_t = Y_{\tilde{X}_t}(x_t)$$  \hfill (A.4)

with initial data $\tilde{x}_0 = e \in V$ for $t \in [0, \tau]$, and $\tilde{X} \in WG_p(V)$, solves (A.4) with initial data $\tilde{x}_\tau = \tilde{x}_\tau$ for $t \in [\tau, T]$. Then the rough path obtained by concatenating $\tilde{X}_t$ and $\mathbf{X}_t$ in the sense of Lemma A.1 solves the RDE (A.4) with initial data $x_0 = e$ for $t \in [0, T]$.

**Proof.** We only have to check the definition of an RDE solution for time $s < \tau < t$, that is, times $s < t$ which straddle $\tau$. We write $X = (x, \mathbf{X})$ for the concatenated path and $G(x)$ for $Y'(x)Y(x)$. We have

$$x_{s,t} = x_{s,\tau} + x_{\tau,t}$$

$\simeq Y(x_{s,\tau})Z_{s,\tau} + G(x_{s,\tau})Z_{s,\tau} + Y(x_{\tau})Z_{\tau,t} + G(x_{\tau})Z_{\tau,t}$

$\simeq Y(x_{s,\tau})Z_{s,\tau} + [Y(x_{s,\tau})Z_{s,\tau} + G(x_{s,\tau})Z_{s,\tau} + G(x_{s,\tau})Z_{s,\tau}]$

$\simeq Y(x_{s,\tau})Z_{s,\tau} + [Y'(x_{s,\tau})Y(x_{s,\tau})Z_{s,\tau} + G(x_{s,\tau})Z_{s,\tau} + G(x_{s,\tau})Z_{s,\tau}]$

$= Y(x_{s,\tau})Z_{s,\tau} + G(x_{s,\tau})Z_{s,\tau} + \mathbf{Z}_{s,\tau} + G(x_{s,\tau})Z_{s,\tau}$

$= Y(x_{s,\tau})Z_{s,\tau} + G(x_{s,\tau})Z_{s,\tau} \quad \text{(Chen’s identity).}$
The second-order term is simpler; we have
\[
X_{s,t} = X_{s,r} + X_{r,t} + x_{s,r} \otimes x_{r,t} \\
\simeq Y(x_s) \otimes Y(x_s)Z_{s,r} + Y(x_r) \otimes Y(x_r)Z_{r,t} + Y(x_s) \otimes Y(x_r)[z_{s,r} \otimes z_{r,t}] \\
\simeq Y(x_s) \otimes Y(x_s)[Z_{s,r} + Z_{r,t} + z_{s,r} \otimes z_{r,t}] = [Y(x_s) \otimes Y(x_s)]Z_{s,t},
\]
as desired. \[\square\]

### A.2. Pushforwards of rough paths

In this subsection introduce the notion of a pushforward of a rough path between two Banach spaces and record its elementary properties (cf. also [5]).

**Definition A.3.** Suppose that \( \varphi \in C^2(W, V) \) and \( Z \inWG_p(W) \); then the push-forward of \( Z \) by \( \varphi \) is defined by
\[
\varphi_*Z := \varphi(z_0) + \int d\varphi(dZ).
\]
In more detail we are letting
\[
[\varphi_*Z]_0 := \varphi(z_0), \quad [\varphi_*Z]_{s,t}^1 = \left[ \int d\varphi(dZ) \right]_{s,t}^1, \quad \text{and} \quad [\varphi_*Z]_{s,t}^2 = \left[ \int d\varphi(dZ) \right]_{s,t}^2.
\]
Note that \( \varphi_*Z \inWG_p(V) \). The first level of the pushforward of a rough path has a more explicit representation.

**Lemma A.4.** For \( \varphi \in C^2(W, V) \) and \( Z \inWG_p(W) \) we have \( [\varphi_*Z]_{s,t}^1 = \varphi(z_t) - \varphi(z_s) \). In particular, Definition A.3 may also be stated as
\[
[\varphi_*Z]_{s,t}^1 = \varphi(z_s) \quad \text{and} \quad [\varphi_*Z]_{s,t}^2 = \left[ \int d\varphi(dZ) \right]_{s,t}^2 \simeq [\varphi'(z_s) \otimes \varphi'(z_s)]Z_{s,t}.
\]

**Proof.** From the symmetry of \( \varphi'' \) and the fact that \( Z \inWG_p(W) \) we may conclude that \( \varphi''(z_s)Z_{s,t} = \frac{1}{2} \varphi''(z_s)[z_{s,t} \otimes z_{s,t}] \). Using this observation along with Taylor’s Theorem shows that
\[
[\varphi_*Z]_{s,t}^1 = \varphi'(z_s)z_{s,t} + \varphi''(z_s)Z_{s,t} \\
= \varphi'(z_s)z_{s,t} + \frac{1}{2} \varphi''(z_s)[z_{s,t} \otimes z_{s,t}] = \varphi(z_t) - \varphi(z_s) + O(|z_{s,t}|^3) \\
\simeq \varphi(z_t) - \varphi(z_s).
\]
As both ends of this equation are continuous additive functionals, we may conclude using Remark 2.11 that \( [\varphi_*Z]_{s,t}^1 = \varphi(z_t) - \varphi(z_s) \). \[\square\]

**Theorem A.5** (Integration of pushforwards). Suppose that \( Z \inWG_p(W) \), \( \varphi \in C^2(W, V) \) and \( \alpha \in C^2(V, \text{End}(V, U)) \) is a 1-form on \( V \) with values in \( U \). Then
\[
\left( \varphi^*\alpha \right)(dZ) = \int \alpha(d[\varphi_*Z]).
\]

**Proof.** By definition \( \beta := \varphi^*\alpha \) is a \( U \)-valued one form on \( W \) which is determined by
\[
\beta(z)v = \alpha(\varphi(z))\varphi'(z)v \in U \quad \text{for all } z, v \in W.
\]
Therefore,
\[
\left[ (\phi^* \alpha)(dZ) \right]_{s, t, \lambda} = \left[ \beta(dZ) \right]_{s, t, \lambda} \cong \left[ \beta(Z) Z^1_{s, t} + \beta'(Z) Z_{s, t} \right] \oplus \left[ \beta(Z) \otimes (Z_{s, t}) \right]
\]
\[
= \left[ \alpha(\phi(Z)) \phi'(Z) Z^1_{s, t} + \alpha'(\phi(Z)) \phi'(Z) \otimes \phi'(Z) Z_{s, t} + \alpha(\phi(Z) \phi''(Z) Z_{s, t} \right] \oplus \left[ \alpha(\phi(Z)) \phi'(Z) \otimes \phi'(Z) Z_{s, t} \right] \]
\[
\simeq \left[ \alpha(\phi(Z)) [\phi, Z]_{s, t}^1 + \alpha'(\phi(Z)) \phi'(Z) \otimes \phi'(Z) Z_{s, t} \right] \oplus \left[ \alpha(\phi(Z)) \phi'(Z) \otimes \phi'(Z) Z_{s, t} \right] \]
\[
\simeq \left[ \alpha(d[\phi, Z]) \right]_{s, t, \lambda}
\]
which suffices to complete the proof.

\[\square\]

**Corollary A.6** (Functoriality of pushforwards). Let \( Z \in WG_p(W), \phi \in C^2(W, V), \psi \in C^2(V, U) \); then \( (\psi \circ \phi)_* (Z) = \psi_* (\phi_* (Z)) \).

**Proof.** By definition,
\[
[\psi_* (\phi_* (Z))]_t = \psi ([\phi_* (Z)]_t) = \psi (\phi(z)) = [(\psi \circ \phi)_* (Z)]_t.
\]
Moreover, since
\[
(\phi^* d\psi) (v_x) = d\psi (\phi_* v_x) = d(\psi \circ \phi)(v_x),
\]
we have from Theorem A.5 that
\[
[\psi_* (\phi_* (Z))]_{s, t} = \left[ \int d\psi (d\phi_* (Z)) \right]_{s, t} = \left[ (\phi^* d\psi)(dZ) \right]_{s, t}
\]
\[
= \left[ \int d(\psi \circ \phi)(dZ) \right]_{s, t} = [(\psi \circ \phi)_* (Z)]_{s, t}.
\]

\[\square\]

**Appendix B. Proof of Theorem 5.5**

**Proof of Theorem 5.5.** The conditions in equation (5.4) may be restated as follows: \((m, g) \in M \times \text{End}(\mathbb{R}^d, E)\) is in \(O_m(M)\) if and only if \(Q(m) g = 0\) and \(g^* g = I_{\mathbb{R}^d}\). This observation shows that the function, \(G\), in equation (5.6) has been manufactured so that \(\pi^{-1}(U) = G^{-1} (\{0, 0, 0\})\). So, in order to finish the proof, it suffices to show that the differential, \(G'\), of \(G\) is surjective at all points \((m, g) \in \pi^{-1}(U) \subset O(M)\). In order to simplify notation, let \(q := Q(m), p = P(m),\) and
\[
\dot{q} := (\partial_\xi Q)(m) = \frac{d}{dt} \bigg|_{t=0} Q(m + \xi).
\]
Given \((\xi, h) \in \text{Hom}(\mathbb{R}^d, E)\) and \((m, g) \in O(M)\) a simple computation shows
\[
G'(m, g)(\xi, h) = (\partial_{(\xi, h)} G)(m, g) = \frac{d}{dt} \bigg|_{t=0} G(m + \xi, g + \theta h)
\]
\[
= \left( (\partial_\xi F)(m), (\partial_\xi Q)(m) g, 0 \right) + (0, Q(m) h, h^* g + g^* h)
\]
\[
= (F'(m) \xi, q g + q h, h^* g + g^* h).
\]

(B.1)

Since \(pg = g\) and \(qg = 0\), we know that \(h^* g = h^* pg = (ph)^* g\) and hence
\[
h^* g + g^* h = h^* g + (h^* g)^* = (ph)^* g + g^* (ph)
\]
and so we may rewrite equation (B.1) as

\[ G'(m, g)(ξ, h) = (F'(m)ξ, qpg + qh, (ph)^* g + g^*(ph)) = (F'(m)ξ, qgg + qh, (ph)^* g + g^*(ph)). \]

From this expression and the following observations: (1) \( ph \) and \( qh \) may be chosen to be arbitrary linear transformation from \( \mathbb{R}^d \) to \( \tau_m M \) and \( \tau_m M^\perp \), respectively; (2) \( \text{Nul}(g^*)^\perp = \text{Ran}(g) = \text{Ran}(p) \); and (3) \( F'(m) \) is surjective, it is now easily verified (take \( ph = gB \) where \( B \in S_d \)) that \( G'(m, g) \) is surjective as well. As a consequence of \( O(M) \) being an embedded submanifold with local defining function \( G \), it follows that

\[ \tau_{(m, g)} O(M) = \text{Nul}(G'(m, g)) = \{ (ξ, h) : (F'(m)ξ, (ξ,h)(Q(m)g + Q(m)h, h^* g + g^* h) = (0, 0, 0) \} = \{ (ξ, h)_{(m, g)} : ξ \in \tau_m M, Q(m)h = −(∂Q)(m)g and g^* h \in \text{so}(d) \}. \]
