(Communicated by Fioralba Cakoni)

Abstract. In this paper we will show the duality between the range test (RT) and no-response test (NRT) for the inverse boundary value problem for the Laplace equation in \( \Omega \setminus \overline{D} \) with an unknown obstacle \( D \subseteq \Omega \) whose boundary \( \partial D \) is visible from the boundary \( \partial \Omega \) of \( \Omega \) and a measurement is given as a set of Cauchy data on \( \partial \Omega \). Here the Cauchy data is given by a unique solution \( u \) of the boundary value problem for the Laplace equation in \( \Omega \setminus \overline{D} \) with homogeneous and inhomogeneous Dirichlet boundary condition on \( \partial D \) and \( \partial \Omega \), respectively. These testing methods are domain sampling methods to estimate the location of the obstacle using test domains and the associated indicator functions. Also both of these testing methods can test the analytic extension of \( u \) to the exterior of a test domain. Since these methods are defined via some operators which are dual to each other, we could expect that there is a duality between the two methods. We will give this duality in terms of the equivalence of the pre-indicator functions associated to their indicator functions. As an application of the duality, the reconstruction of \( D \) using the RT gives the reconstruction of \( D \) using the NRT and vice versa. We will also give each of these reconstructions without using the duality if the Dirichlet data of the Cauchy data on \( \partial \Omega \) is not identically zero and the solution to the associated forward problem does not have any analytic extension across \( \partial D \). Moreover, we will show that these methods can still give the reconstruction of \( D \) if we a priori knows that \( D \) is a convex polygon and it satisfies one of the following two properties: all of its corner angles are irrational and its diameter is less than its distance to \( \partial \Omega \).

1. Introduction. We will first set up our inverse problem. To begin with let \( \Omega \subseteq \mathbb{R}^n \) for \( n = 2, 3 \) be a bounded domain with \( C^2 \) boundary \( \partial \Omega \). Physically \( \Omega \) is a medium and it can be either homogeneous electric or heat conductive medium with conductivity 1. Let \( D \subseteq \Omega \) be a domain with Lipschitz boundary \( \partial D \) such that
\( \Omega \setminus \overline{D} \) is connected. Then the voltage or temperature of electric or heat denoted by \( u \) satisfies the following boundary value problem

\[
\begin{cases}
    \Delta u = 0 & \text{in } \Omega \setminus \overline{D}, \\
    u = 0 & \text{on } \partial D, \\
    u = f & \text{on } \partial \Omega,
\end{cases}
\]  

(1)

where \( f \) is taken from the \( L^2 \)-based Sobolev space \( H^{1/2}(\partial \Omega) \) of order \( 1/2 \) on \( \partial \Omega \). The physical meaning of the Dirichlet boundary condition for \( \partial D \) is the earthing boundary for an electric conductive medium and the prescribed 0 temperature for a heat conductive medium.

It is well known that (1) is well-posed. That is for any given \( f \in H^{1/2}(\partial \Omega) \) of order \( 1/2 \) on \( \partial \Omega \), there exists a unique solution \( u = u_f \) in the \( L^2 \)-based Sobolev space \( H^1(\Omega \setminus \overline{D}) \) of order 1 in \( \Omega \setminus \overline{D} \) to (1) such that

\[
\|u\|_{H^1(\Omega \setminus \overline{D})} \leq C\|f\|_{H^{1/2}(\partial \Omega)}
\]

for some constant \( C > 0 \) which does not depend on \( f \) and \( u \). Henceforth we call such a \( C > 0 \) general constant, which may differ from place to place, but we will use the same notation \( C \).

Based on this well-posedness, one can calculate the Neumann derivative \( \partial_{\nu} u_f \) on \( \partial \Omega \) which belongs to the dual space \( H^{-1/2}(\partial \Omega) \) of \( H^{1/2}(\partial \Omega) \), and this means that we can measure either electric current or heat flux on \( \partial \Omega \). The pair \( \{f, \partial_{\nu} u_f|_{\partial \Omega}\} \) with the unit normal \( \nu \) of \( \partial \Omega \) directed outside \( \Omega \) is called a Cauchy data. Throughout this paper, we assume that the boundary data \( f \) on \( \partial \Omega \) is a non-identically zero function, and \( u \in H^1(\Omega \setminus \overline{D}) \) always stand for the solution to (1). Then our inverse boundary value problem can be stated as follows.

**Inverse Boundary Value Problem**

Given a set of Cauchy data \( \{f|_{\partial \Omega}, \partial_{\nu} u_f|_{\partial \Omega}\} \) taken as our measurement, identify \( D \) from this measurement.

The uniqueness of this inverse problem has been already known very early for example from the proof given for the uniqueness of identifying an unknown rigid inclusion inside an isotropic elasticity medium [3]. Also the stability estimate for the identification is known for the conductivity equation [1] and even for the isotropic elasticity system [10, 20]. The next natural problem is to give a reconstruction method to reconstruct \( D \) from the given Cauchy data. We are particularly interested in the reconstruction methods called the range test (RT) and the no response test (NRT) very well known in the inverse scattering problem. The RT and NRT were introduced by Potthast-Sylvester-Kusiak in [24] and Luke-Potthast in [17] both for the inverse acoustic scattering problem to identify a scatterer such as a sound soft or sound hard obstacle, respectively. There are single wave RT/NRT and multiple waves RT/NRT. The corresponding measurements are the far field of the scattered wave generated by one incident plane wave and the scattering amplitude generated by multiple incident waves, respectively. Here it should be remarked that the multiple incident waves mean infinitely many incident waves. The multiple waves RT/NRT can recover the scatterer, but the single wave RT/NRT in general can only give the upper estimate of the convex scattering support. Moreover the single wave RT gives an easy test for analytic extension of \( u \) (see [24]). For further information about the RT/NRT for the inverse acoustic scattering problems see [21], [17] and [22]. RT/NRT were also applied to inverse scattering problems for electromagnetic

*Inverse Problems and Imaging* Volume 15, No. 2 (2021), 367–386
Duality between RT and NRT waves ([23]) and the Oseen flow linearized around a constant velocity field ([25]). We will refer the single wave RT and NRT adapted to our inverse problem by RT and NRT which will be given in Section 2 and Section 3, respectively. There is a duality known between the RT and NRT for the inverse scattering problem for acoustic waves ([21]) and for the Oseen flow linearized at constant velocity field ([25]). The RT/NRT for the inverse boundary value problems become a bit more complicated than those for the inverse scattering problems. The aims of this paper are to give the corresponding duality for our inverse problem, and by using either the RT or the NRT to test the analytic extension of the solution \( u \) of (1), reconstruct \( D \) under the assumption that \( u \) does not have analytic extension across \( \partial D \).

Our main results are the following three theorems.

**Theorem 1.1.** There is a duality between the RT and NRT for the inverse boundary value problem. Its details will be given in Section 3.

As an application of testing the analytic extension of \( u \) and the above duality theorem, we have the following reconstruction of \( D \).

**Theorem 1.2.** Consider the inverse boundary value problem. Then either using the RT or NRT, we can reconstruct \( D \) from the above given Cauchy data if \( u \) does not have any analytic extension across \( \partial D \). Their details will be given in Section 4 for the RT and Section 5 for the NRT, respectively.

**Remark 1.**

(i) The same result given as in Theorem 1.1 is true for an unknown \( D \) with Neumann boundary condition at \( \partial D \).

(ii) It can be noticed from these two theorems and a short introduction on the RT/NRT given before the theorems that the key behind the RT/NRT is the analyticity. These theorems can be further generalized to equations with analytic coefficients and the associated Green functions have the jump property, the decaying property at infinity, the mapping property and the Fredholm index zero property for the trace of double layer potentials.

A typical example that \( u \) does not have any analytic extension across \( \partial D \) is the case \( \partial D \) is not analytic everywhere (see Corollary 2.3 of [11]). This assumption on \( u \) is very strong. We can relax this assumption if we a priori know that \( D \) is a convex polygon and it has either irrationally angled corners (see Section 6 for its definition) or the distance property (see the next theorem for its definition). More precisely we have the following theorem.

**Theorem 1.3.** Consider the inverse boundary value problem. Suppose we know that \( D \) is a convex polygon. Assume that all of its corners have irrational angle or it satisfies the distance property given as

\[
\text{diam}(D) < \text{dist}(D, \partial\Omega),
\]

where \( \text{diam}(D) \) and \( \text{dist}(D, \partial\Omega) \) denote the diameter of \( D \) and the distance between \( D \) and \( \partial\Omega \), respectively. Further we assume the following existence of a priori convex polygon given as follows. There exists a convex polygon \( D_0 \) such that \( D \subset D_0 \subseteq \Omega \) and \( \Omega \setminus D_0 \) is connected. Then either using the RT or NRT, we can reconstruct \( D \) from the above given Cauchy data.
Remark 2.

(i) The existence of a priori convex polygon $D_0$ is necessary only in the case the NRT itself is used for the reconstruction. If we use the NRT with the duality between RT and NRT, we don’t need to have this $D_0$.

(ii) Replace the Dirichlet condition in (1) by the Neumann condition, and assume that $u$ is not a constant function. Further let $D$ be a convex polygon which satisfies the distance property. Then Ikehata ([13]) gave a reconstruction of $D$ from one set of Cauchy data by using his enclosure method.

Since there is a huge literature on the reconstruction methods for our inverse problem, we only give some major reconstruction methods by citing one paper for each method which we came across with strong interest. So we ask the readers to consult the literature there in and make further search to collect more information about the methods. They are iterative methods using the domain derivative [16], topological derivative [4], level set [6] and quasi-reversibility [5]. Also there are non-iterative methods using the polarization tensor [2], a family of special solutions called the complex geometrical optics solutions as test functions [14], nearly orthogonal probing functions [7] and point source [11]. The second non-iterative method is called the enclosure method which we already mentioned in Remark 2. We remark that this last method was given for the inverse scattering problem for the Helmholtz equation, but it can be adapted to the inverse boundary value problem for the Laplace equation to give a reconstruction of an unknown obstacle with non-analytic boundary.

In the rest of this paper except Section 6 and Appendix we only consider the three dimensional case i.e. $n = 3$ for the simplicity of description. Also we organize the rest of this paper as follows. In Section 2 we show that for a domain $G \subset \Omega$ likewise $D$, the analytic extension of $u$ to $\Omega \setminus \overline{G}$ can be characterized by the RT. Such a domain will be called a test domain for RT and NRT. Then in Section 3 we will introduce the NRT and prove the duality between the RT and NRT. Based on the characterization of analytic extension of $u$ in terms of the RT, we will reconstruct $D$ from the given Cauchy data in Section 4 by using the RT if the solution $u$ to (1) does not have any analytic extension across $\partial D$. Further in Section 5, we will reconstruct $D$ by using the NRT under the same situation as for the RT. For these two reconstructions we have to emphasize that we will not use the duality. In the last section we will pick up the case that $D$ is a convex polygon and prove Theorem 1.3. Appendix gives some propositions and their proofs cited in Sections 2 and 6.

2. Analytic extension and RT. We first consider a version of the range test for the inverse boundary value problem for the Laplace equation. As we mentioned before, the RT was introduced in [17] for the inverse scattering problem for the Helmholtz equation.

For $f \in H^{1/2}(\partial \Omega)$, we recall that $u = u^f \in H^1(\Omega \setminus \overline{D})$ is the solution to (1). Any domain $G \subset \Omega$ likewise $D$ is called a test domain. For a test domain $G$, we want to characterize the analytic extension of $u$ to $\Omega \setminus \overline{G}$ by using the RT, and by using this characterization, we want to analyze the analytic extension of $u$ across $\partial D$. The analytic extension of $u$ across $\partial D$ is defined as follows.

Definition 2.1. Let $\Omega$ and $D$ be open bounded sets given as before. A harmonic function $v \in H^1(\Omega \setminus \overline{D})$ is said to have an analytic extension across $\partial D$ if and only...
if there exists a domain $D'$ with Lipschitz boundary $\partial D'$ such that
\[
\mathcal{D}' \subseteq \mathcal{D}, \quad \mathcal{H}^{n-1}(\partial D \cap \partial D') > 0,
\]
and a function $v' \in H^1(\Omega \setminus \mathcal{D})$ such that
\[
\begin{cases}
\Delta v' = 0 & \text{in } \Omega \setminus \mathcal{D}, \\
v' = v & \text{in } \Omega \setminus \mathcal{D}.
\end{cases}
\]
Here $\mathcal{H}^{n-1}(A)$ stands for the $(n-1)$-dimensional Hausdorff measure of a measurable set $A$.

In order to introduce the RT, we need some preparation. To begin with let $v \in H^1(\Omega)$ be the unique solution to the boundary value problem:
\[
\begin{cases}
\Delta v = 0 & \text{in } \Omega, \\
v = f & \text{on } \partial \Omega
\end{cases}
\]
and consider $w := u - v$. We call this $v$ the back ground solution. Then $w$ satisfies
\[
\begin{cases}
\Delta w = 0 & \text{in } \Omega \setminus \mathcal{D}, \\
w = -v & \text{on } \partial D, \\
w = 0 & \text{on } \partial \Omega.
\end{cases}
\]

Denote by $G_y(\cdot) = G(\cdot, y)$ be the Green function of $\Delta$ in $\Omega$ with Dirichlet boundary condition on $\partial \Omega$. Let $S[\varphi]$ be the single-layer potential defined as $S : H^{-1/2}(\partial \mathcal{G}) \rightarrow H^1(\Omega \setminus \partial \mathcal{G})$ by
\[
S[\varphi](x) = \int_{\partial \mathcal{G}} G(x, y) \varphi(y) \, d\sigma(y), \quad \varphi \in H^{-1/2}(\partial \mathcal{G}), \; x \in \Omega \setminus \partial \mathcal{G}
\]
with the surface element $d\sigma(y)$ of $\partial \mathcal{G}$. Further define the operator
\[
R : H^{-1/2}(\partial \mathcal{G}) \rightarrow H^{-1/2}(\partial \Omega)
\]
by
\[
R[\varphi] = \partial_{\nu} S[\varphi] \in H^{-1/2}(\partial \Omega), \quad \varphi \in H^{-1/2}(\partial \mathcal{G}),
\]
where $\nu$ is the unit normal of $\partial \Omega$ directed into the exterior of $\Omega$. Of course $R$ is a compact linear operator with the kernel $\partial_{\nu} G(x, y)$.

Now consider the solvability of the boundary integral equation:
\[
R[\varphi](x) = \partial_{\nu} w(x), \quad x \in \partial \Omega
\]
with respect to $\varphi \in H^{-1/2}(\partial \mathcal{G})$. Then we have the following theorem.

**Theorem 2.2.** (5) is solvable if and only if $w$ can be analytically extended to $\Omega \setminus \mathcal{G}$ and $w_+ \big|_{\partial \mathcal{G}} \in H^{1/2}(\partial \mathcal{G})$, where $w_+ = w\big|_{\Omega \setminus \mathcal{G}}$.

**Proof.** We first prove the only if part. Let $\varphi \in H^{-1/2}(\partial \mathcal{G})$ be a solution of (5). Let $z = S[\varphi]$. Then by using (5), $z \in H^1(\Omega \setminus \mathcal{G})$ and it satisfies
\[
\begin{cases}
\Delta z = 0 & \text{in } \Omega \setminus \mathcal{G}, \\
\partial_{\nu} z = \partial_{\nu} w & \text{on } \partial \Omega, \\
z = 0 & \text{on } \partial \Omega.
\end{cases}
\]

Compare this with
\[
\begin{cases}
\Delta w = 0 & \text{in } \Omega \setminus \mathcal{D}, \\
w = 0 & \text{on } \partial \Omega.
\end{cases}
\]
Then by the unique continuation property (UCP) of solutions for the Laplace equation, we have \( w = z \) in \( \Omega \setminus (\overline{D} \cup \overline{M}) \), where \( M \subseteq \Omega \) is the minimal domain\(^1\) such that the harmonic function \( z \) can be analytically extended into \( \Omega \setminus M \). Hence \( w \) can be analytically extended into \( \Omega \setminus \overline{G} \) which implies \( w = S[\varphi] \) on \( \partial G \). Then, since \( S : H^{-1/2}(\partial G) \to H^{1/2}(\partial G) \), we have \( w_+|_{\partial G} \in H^{1/2}(\partial G) \), where we have abused the notation \( S \) used to denote the single-layer potential.

Next, we prove the if part. Assume that \( w \) can be analytically extended to \( \Omega \setminus \overline{G} \) and \( w_+|_{\partial G} \in H^{1/2}(\partial G) \). By the bijectivity of \( S : H^{-1/2}(\partial G) \to H^{1/2}(\partial G) \) which will be shown in Proposition A.1, there exist a unique \( \varphi \in H^{-1/2}(\partial G) \) which solves \( S[\varphi] = w_+|_{\partial G} \) on \( \partial G \). Then \( z := S[\varphi] \) satisfies

\[
\begin{align*}
\Delta z &= 0 \quad \text{in } \Omega \setminus \overline{G}, \\
z &= 0 \quad \text{on } \partial \Omega, \\
z &= w_+|_{\partial G} \quad \text{on } \partial G.
\end{align*}
\]

Compare this with

\[
\begin{align*}
\Delta w &= 0 \quad \text{in } \Omega \setminus \overline{G}, \\
w &= 0 \quad \text{on } \partial \Omega, \\
w &= w_+|_{\partial G} \quad \text{on } \partial G.
\end{align*}
\]

Then, by the uniqueness of solutions to the boundary value problem in \( \Omega \setminus \overline{G} \), we have \( z = w \) in \( \Omega \setminus G \). Hence

\[ R[\varphi] = \partial_\nu S[\varphi] = \partial_\nu z = \partial_\nu w \text{ on } \partial \Omega. \]

\[
\square
\]

For any test domain \( G \), Theorem 2.2 tells us that the analytic extension of the solution \( w \in H^1(\Omega \setminus \overline{D}) \) to \( \Omega \setminus \overline{G} \) can be tested by the solvability of (5) with respect to \( \varphi \in H^{-1/2}(\partial G) \). We will interpret this solvability using the regularization theory (see for instance Theorem 3.1.10 of [21]), and compact operator. Consider the Tikhonov regularized solution \( \varphi_\alpha \in H^{-1/2}(\partial G) \) with a regularization parameter \( \alpha > 0 \) of the equation \( R[\varphi] = \partial_\nu w \) in \( H^{-1/2}(\partial \Omega) \). That is

\[
\varphi_\alpha = (\alpha I + R^* R)^{-1} R^* \partial_\nu w,
\]

where \( R^* : H^{-1/2}(\partial \Omega) \to H^{-1/2}(\partial G) \) is the adjoint operator of \( R \). Then by the regularization theory (see for instance Theorem 3.1.10 of [21]), we have

\[
\begin{align*}
\partial_\nu w \in \text{Rge}(R) \implies \varphi_\alpha \to \varphi \quad (\alpha \to 0) \text{ in } H^{-1/2}(\partial G), \\
\partial_\nu w \not\in \text{Rge}(R) \implies \lim_{\alpha \to 0} \|\varphi_\alpha\|_{H^{-1/2}(\partial G)} = \infty.
\end{align*}
\]

Hence allowing the limit becomes infinity, we can test whether \( \partial_\nu w \) belongs to \( \text{Rge}(R) \) by letting \( \lim_{\alpha \to 0} \|\varphi_\alpha\|_{H^{-1/2}(\partial G)} \). Finally combining this with Theorem 2.2, we have the following equivalence:

\[
w \text{ can be analytically extended to } \Omega \setminus \overline{G} \text{ and } w_+|_{\partial G} \in H^{1/2}(\partial G) \iff \text{finite } \lim_{\alpha \to 0} \|\varphi_\alpha\|_{H^{-1/2}(\partial G)} \text{ exists.}
\]

\( ^1 \) \( M \) is the minimal domain in the sense that \( u \) can be extended into \( \Omega \setminus M \) but not into any \( \Omega \setminus N \) for \( N \subseteq M \).
Hence we can use \( \lim_{\alpha \to 0} \| \varphi_\alpha \|_{H^{-1/2}(\partial \Omega)} \) as a pre-indicator function to test the analytic extension of \( w \) across \( \partial G \). This is the range test (RT) and its indicator function will be given in Section 4.

3. NRT and its duality between RT. In this section we will show the duality between the RT and the NRT for the inverse boundary value problem by showing the equivalence of the pre-indicator functions for the both testing methods. There is already the corresponding duality known for the inverse scattering problem by a very short argument ([21]). We will adopt the argument in [21] for our inverse problem, but we will add more supplementary arguments. To begin with recall that \( R^* : H^{-1/2}(\partial \Omega) \to H^{-1/2}(\partial G) \) was the adjoint operator of \( R : H^{-1/2}(\partial G) \to H^{-1/2}(\partial \Omega) \). Then the pre-indicator function and the indicator function of the NRT for the test domain \( G \) are the same and defined by

\[
I_{NRT}(G) := \sup_{\zeta \in H^{-1/2}(\partial G), \| R^* \zeta \| \leq 1} |(\zeta, \partial_\nu w)|,
\]

where we have denoted the norm of \( H^{-1/2}(\partial G) \) and inner product of \( H^{-1/2}(\partial \Omega) \) by \( \| \cdot \| \) and \( (\cdot, \cdot) \), respectively. Note that the pre-indicator function of RT is based on \( \| \cdot \| \) while the pre-indicator function of NRT is based on \( R^* \). This indicates some duality between the RT and NRT.

Now we are ready to state the duality in terms of the equivalence of the pre-indicator functions of RT and NRT as follows.

**Proposition 1.** Let \( \varphi_\alpha \in H^{-1/2}(\partial G) \) be the Tikhonov regularized solution (6) of (5) with regularization parameter \( \alpha > 0 \). Then we have

\[
\lim_{\alpha \to 0} \| \varphi_\alpha \|^2 = \sup_{\zeta \in H^{-1/2}(\partial G), \| R^* \zeta \| \leq 1} |(\zeta, \partial_\nu w)|.
\]

We remark that this equality holds even in the case both sides of this equality are infinite.

**Proof.** By \( \varphi_\alpha = (\alpha I + R^* R)^{-1} R^* \partial_\nu w \) and the denseness of the range \( \text{Rge}(R^*) \) which will be proved in Theorem A.2 of Appendix, we first have

\[
\lim_{\alpha \to 0} \| \varphi_\alpha \|^2 = \lim_{\alpha \to 0} \sup_{\| z \| \leq 1} |(z, \varphi_\alpha)|
\]

\[
= \lim_{\alpha \to 0} \sup_{\| z \| \leq 1} |(z, (\alpha I + R^* R)^{-1} R^* \partial_\nu w)|
\]

\[
= \lim_{\alpha \to 0} \sup_{z \in \text{Rge}(R^*), \| z \| \leq 1} |(z, (\alpha I + R^* R)^{-1} R^* \partial_\nu w)|
\]

by abusing the notation “(, )” to denote the inner product of the Hilbert space \( H^{-1/2}(\partial G) \).

Since \( R(\alpha I + R^* R)^{-1} = (\alpha I + RR^*)^{-1} R \) and (11), we have

\[
\lim_{\alpha \to 0} \| \varphi_\alpha \|^2 = \lim_{\alpha \to 0} \sup_{z \in \text{Rge}(R^*), \| z \| \leq 1} |((\alpha I + RR^*)^{-1} R z, \partial_\nu w)|
\]

\[
= \lim_{\alpha \to 0} \sup_{R^* \zeta \leq 1} |((\alpha I + RR^*)^{-1} RR^* \zeta, \partial_\nu w)|,
\]

where we have put \( z = R^* \zeta \) with \( \zeta \in H^{-1/2}(\partial \Omega) \).
Finally we want to show
\[ \lim_{\alpha \to 0} \sup_{\|R^*\zeta\| \leq 1} |((\alpha I + RR^*)^{-1}RR^*\zeta, \partial_\nu w)| = \sup_{\zeta \in H^{-1/2}(\partial\Omega), \|R^*\zeta\| \leq 1} |(\zeta, \partial_\nu w)|. \]  

To begin, let \((\mu_n, \varphi_n, \psi_n)\) be the singular system of \(R^*: H^{-1/2}(\partial\Omega) \to H^{-1/2}(\partial G)\). The bracket \(\langle \cdot, \cdot \rangle\) used in the sequel for proving (13) is the inner product of the Hilbert space \(H^{-1/2}(\partial\Omega)\). Define \(I\) and \(J\) by
\[
I = \lim_{\alpha \to 0} \sup_{\|R^*\zeta\| \leq 1} |((\alpha I + RR^*)^{-1}RR^*\zeta, \partial_\nu w)|, \\
J = \sup_{\|R^*\zeta\| \leq 1} |(\zeta, \partial_\nu w)|.
\]

We will show the identity \(I = J\) even in the case \(I, J\) are infinite. Observe that
\[
\|R^*\zeta\|^2 = \sum_{n=1}^{\infty} \lambda_n |\zeta_n|^2, \\
\tag{14}
((\alpha I + RR^*)^{-1}RR^*\zeta, \partial_\nu w) = \sum_{n=1}^{\infty} \frac{\lambda_n}{\alpha + \lambda_n} \zeta_n (\partial_\nu w)_n
\]

with \(\lambda_n = \mu_n^2, \zeta_n = (\zeta, \varphi_n), (\partial_\nu w)_n = (\varphi_n, \partial_\nu w)\).

Now we adjust \(\zeta\) by multiplying each of its \(\zeta_n\) by a unimodular complex number such that \(\zeta_n (\partial_\nu w)_n \geq 0\). Then the modulus of the second quantity of (14) becomes larger, but \(\|R^*\zeta\|\) does not change. We call such \(\zeta \in H^{-1/2}(\partial\Omega)\) positive and denote it by \(\zeta^+\). Hence we have
\[
I = \sup_{\alpha, \zeta^+} A(\zeta^+, \alpha) \text{ with } A(\zeta^+, \alpha) := \sum_{n=1}^{\infty} \frac{\lambda_n}{\alpha + \lambda_n} \zeta^+_n (\partial_\nu w)_n, \\
\tag{15}
\]

where \(\sup_{\alpha, \zeta^+}\) is taken for \(\alpha > 0\) and \(\zeta^+ \in H^{-1/2}(\partial\Omega)\) which satisfies the estimate \(\|R^*\zeta^+\| \leq 1\). Define \(B(\zeta^+)\) by
\[
B(\zeta^+) := \sum_{n=1}^{\infty} \zeta^+_n (\partial_\nu w)_n. \\
\tag{16}
\]

Then by using \(\varphi_n, n \in \mathbb{N}\) is an orthonormal system and the Bessel inequality, it is easy to see that for each fixed \(\zeta^+, A(\zeta^+, \alpha)\) is monotonically increasing as \(\alpha\) becomes small and converges to \(B(\zeta^+)\). Namely we have
\[
A(\zeta^+, \alpha) \nearrow B(\zeta^+) \text{ as } \alpha \searrow 0. \\
\tag{17}
\]

Now consider the following two cases (i) \(I < \infty\) and (ii) \(I = \infty\). First consider the case (i). By (7), \(\partial_\nu w \in \text{Rge}(R) \subset N(R^*)^\perp\). Hence by (15), (16) and (17), we have
\[
I = \sup_{\|R^*\zeta\| \leq 1} \sum_{n=1}^{\infty} \zeta^+_n (\partial_\nu w)_n = \sup_{\|R^*\zeta\| \leq 1} \left| \sum_{n=1}^{\infty} \zeta_n (\partial_\nu w)_n \right| \\
\tag{18}
= \sup_{\|R^*\zeta\| \leq 1} \left| \sum_{n=1}^{\infty} \zeta_n (\partial_\nu w)_n + (Q\zeta, Q(\partial_\nu w)) \right| \\
= \sup_{\|R^*\zeta\| \leq 1} |(\zeta, \partial_\nu w)| = J,
\]

where \(Q: H^{-1/2}(\partial\Omega) \to N(R^*) \subset H^{-1/2}(\partial\Omega)\) is the projection.
Next we consider the case (ii). If \( \partial_v w \in N(R^*)^\perp \), we still can have (18). Hence \( J = \infty \). So let’s assume \( \partial_v w \notin N(R^*)^\perp \). Observe that

\[
J \geq \sum_{n=1}^{\infty} \zeta_n (\partial_v w)_n + (Q\zeta, Q(\partial_v w))
\]

for any \( \zeta \) satisfying \( ||R^*\zeta||^2 = \sum_{n=1}^{\infty} \lambda_n |\zeta_n|^2 \leq 1 \). Since \( Q(\partial_v w) \neq 0 \), we can have

\[
\sup_{||R^*\zeta|| \leq 1} \sum_{n=1}^{\infty} \zeta_n (\partial_v w)_n + (Q\zeta, Q(\partial_v w)) = \infty
\]

by taking \( \zeta_n = 0, n \in \mathbb{N} \) in (19). Hence \( J = \infty \). \( \square \)

4. Reconstruction of unknown obstacle by RT. In this section we will show the reconstruction of the unknown obstacle \( D \) by the RT. First of all, by (7), \( \lim_{n \to 0} ||\varphi_n||_{H^{-1/2}(\partial G)} \) can be either finite or infinite. Based on this we define the indicator function \( I_{RT}(G) \) of RT for a test domain \( G \) by

\[
I_{RT}(G) := \begin{cases} 
\lim_{\alpha \to 0} ||\varphi_n||_{H^{-1/2}(\partial G)} & \text{if the finite limit exists,} \\
\infty & \text{if otherwise.}
\end{cases}
\]

We call a test domain \( G \) positive if it satisfies \( I_{RT}(G) < \infty \). Denote the set of all positive test domains by \( \mathcal{P} \).

By using this indicator function \( I_{RT}(\cdot) \), we can explain more precisely what is the RT. It is a domain sampling method which uses the indicator function \( I_{RT}(\cdot) \) for test domains to reconstruct \( D \) or extract some information about the location of \( D \). The key to this method is (8) which gives

\[
w \text{ can be analytically extended to } \Omega \setminus \overline{G} \text{ and } w_+|_{\partial G} \in H^{1/2}(\partial G)
\]

\[
\iff I_{RT}(G) < \infty.
\]

Then we have the following theorem.

**Theorem 4.1.** Let \( G \) be a test domain. Then we have the followings.

(i) \( \overline{D} \subset \overline{G} \implies I_{RT}(G) < \infty \).

(ii) Let \( \overline{D} \not\subset \overline{G} \) and recall \( u \in H^1(\Omega \setminus \overline{D}) \) is the solution to the boundary value problem (1). If \( u \) admits an analytic extension across \( \partial D \) from \( \Omega \setminus \overline{D} \) into the whole \( \overline{D} \setminus G \), then \( I_{RT}(G) < \infty \).

(iii) Let \( \overline{D} \not\subset \overline{G} \). If the above \( u \) does not admit an analytic extension across \( \partial D \), then \( I_{RT}(G) = \infty \).

As a consequence, if \( u \) does not admit an analytic extension across \( \partial D \), then we have the following reconstruction of \( \overline{D} \) as \( \overline{D} = \cap_{G \in \mathcal{P}} \overline{G} \).

**Proof.** First of all note that by the analyticity of the background solution \( v \) in \( \Omega \), the analytic extension of \( u \) and that of \( w := u - v \) are the same. If \( \overline{D} \subset \overline{G} \), then \( w \) is analytic in \( \Omega \setminus \overline{G} \). Also since \( \partial G \subset \Omega \setminus D \) and \( w \in H^1(\Omega \setminus \overline{D}) \), \( w_+|_{\partial G} \in H^{1/2}(\partial G) \). Hence \( I_{RT}(G) < \infty \). This proves (i).

Next let \( \overline{D} \not\subset \overline{G} \) and assume that \( u \) admits an analytic extension across \( \partial D \) from \( \Omega \setminus \overline{D} \) into the whole \( \overline{D} \setminus G \). Then \( w \) is analytic in \( \Omega \setminus G \). Hence \( I_{RT}(G) < \infty \) which proves (ii).

Now assume \( \overline{D} \not\subset \overline{G} \) and \( u \) does not admit an analytic extension across \( \partial D \). Then we prove \( I_{RT}(G) = \infty \) by contradiction. Suppose \( I_{RT}(G) < \infty \). Then \( w \) is analytic in \( \Omega \setminus \overline{G} \). By the assumption on \( u \), this implies \( \partial D \cap (\Omega \setminus \overline{G}) = \emptyset \). That is \( \partial D \subset \overline{G} \).
But since $D, G$ are connected open sets compactly embedded in $\Omega$, we have $\overline{D} \subset \overline{G}$. This contradicts to $\overline{D} \nsubseteq \overline{G}$. Hence we must have $I_{RT}(G) < \infty$ which proves (iii).

Finally we will prove the last statement. From (i) and (iii), we have $\overline{D} \subset \overline{G} \implies G \in \mathcal{P}$ and $\overline{D} \nsubseteq \overline{G} \implies G \notin \mathcal{P}$, respectively. Hence we have $\overline{D} \subset \overline{G} \iff G \in \mathcal{P}$ which immediately gives $\overline{D} = \cap_{G \in \mathcal{P}} \overline{G}$.

\begin{remark}
Instead of the indicator function $I_{RT}(G)$ for a test domain $G$, if we use a new indicator function $I'_{RT}(G)$ given as
\begin{equation}
I'_{RT}(G) = \begin{cases}
\lim_{\alpha \to 0} \sup_{\beta < \alpha} \| \varphi_{\alpha} - \varphi_{\beta} \|_{H^{-1/2}(\partial G)} & \text{if the finite limit exists,} \\
\infty & \text{if otherwise,}
\end{cases}
\end{equation}
then we have $w$ can be analytically extended to $\Omega \backslash \overline{G}$ and $w_{+}|_{\partial G} \in H^{1/2}(\partial G)$
\begin{equation}
\iff I'_{RT}(G) = 0.
\end{equation}
Hence we can have Theorem 4.1 in terms of this indicator function with obvious changes. We note that it is nice to have (23) instead of $I_{RT}(G) < \infty$ in (21). However the pre-indicator $\lim_{\alpha \to 0} \sup_{\beta < \alpha} \| \varphi_{\alpha} - \varphi_{\beta} \|_{H^{-1/2}(\partial G)}$ of this new $I'_{RT}(\cdot)$ loose the direct connection with the pre-indicator function $I_{NRT}(\cdot)$ of the NRT which will be defined in the next section.

5. Reconstruction of unknown obstacle by NRT. In this section we will show the reconstruction of the unknown obstacle $D$ by the NRT. Needless to say that we can have the reconstruction for the NRT by using the duality. But we pursue a way to provide the reconstruction for the NRT without using the duality. We start with some preparation necessary for showing the reconstruction. To avoid heavy notations, let $X = H^{-1/2}(\partial G)$, $Y = H^{1/2}(\partial \Omega)$. Recall that the operator $R : X \to Y$ was defined by $R[\varphi] = \partial_{\nu} S[\varphi]$ on $\partial \Omega$. Hence
\[ R[\varphi](x) = \int_{\partial G} \partial_{\nu} G(x, y) \varphi(y) \, d\sigma(y), \ x \in \partial \Omega, \]
for $\varphi \in X$.

We also let $X^{*} = H^{1/2}(\partial G)$ and $Y^{*} = H^{-1/2}(\partial \Omega)$ be the dual spaces of $X$ and $Y$, respectively. Also let $(\cdot, \cdot)_{X}$ and $(\cdot, \cdot)_{Y}$ be the inner products in $X$ and $Y$, respectively. Then the adjoint operator $R^{*} : Y \to X$ of $R$ can be given by the relation
\[ (\phi, R^{*} \psi)_{X} = (R \phi, \psi)_{Y}, \ \phi \in X, \ \psi \in Y. \]
Further let $J_{X}$ and $J_{Y}$ be the isometric isomorphism $J_{X} : X \to X^{*}$, $J_{Y} : Y \to Y^{*}$ defined by
\[ (J_{X} \phi)(\psi) = (\psi, \phi)_{X}, \ \phi, \psi \in X, \]
and define $J_{Y}$ in a similar way. Then the dual operator $R^{(*)} : Y^{*} \to X^{*}$ of the operator $R$ and the adjoint operator $R^{*}$ have the relation $R^{*} = J_{X}^{-1} R^{(*)} J_{Y}$. Moreover a direct computation yields that
\begin{equation}
(R^{(*)} \eta)(y) = \int_{\partial \Omega} \partial_{\nu_{x}} G(x, y) \eta(x) \, d\sigma(x), \ y \in \partial G
\end{equation}
for any $\eta \in Y^{*}$.

Observe that
\begin{equation}
\| R^{*} \zeta \|_{X} = \| J_{X}^{-1} R^{(*)} J_{Y} \zeta \|_{X} = \| R^{(*)} J_{Y} \zeta \|_{X^{*}} = \| R^{(*)} \zeta \|_{X^{*}}
\end{equation}
where \( \hat{\zeta} = J_Y \zeta \in Y^* \). Let \( W[\varphi] \) be the double-layer potential for \( \varphi \in Y^* \) defined by

\[
W[\varphi](x) := \int_{\partial \Omega} \partial_\nu G_0(x, y)\varphi(y) \, d\sigma(y),
\]

where \( G_0(x, y) = \frac{1}{4\pi|x-y|} \) for \( x \neq y \) and \( \nu \) is the unit outer normal of \( \partial \Omega \). Then we have the following representations of \( I_{NRT}(G) \).

**Proposition 2.** The indicator function defined by (9) has the following representation

\[
I_{NRT}(G) = \sup_{\hat{\zeta} \in Y^*, \|\hat{\zeta}\|_{X^*} \leq 1} \left| \int_{\partial \Omega} \hat{\zeta} \partial_\nu w \, d\sigma(x) \right|.
\]

Moreover, (27) can be written as

\[
I_{NRT}(G) := \sup_{\varphi \in Y^*, \|\varphi\|_{W^2(\Omega)} \leq 1} \left| \int_{\partial \Omega} (W[\varphi](x)\partial_\nu w(x) + \partial_\nu W[\varphi](x)v(x)) \, d\sigma(x) \right|,
\]

where \( w = u - v \) and \( v \in H^1(\Omega) \) is the solution to \( \Delta v = 0 \) in \( \Omega \) with \( v = f \) on \( \partial \Omega \).

**Proof.** By the definitions of \( \hat{\zeta} \) given after (25) and \( J_Y \), we have

\[
(\zeta, \partial_\nu w)_Y = (J_Y \zeta, \partial_\nu w) = \hat{\zeta}(\partial_\nu w) = \int_{\partial \Omega} \hat{\zeta} \partial_\nu w \, d\sigma(x).
\]

Then combining this with (25) we have (27).

Next, by the jump formula of the double-layer potential \( W[\varphi] \), we have

\[
W[\varphi](x) = -\frac{1}{2} \varphi(x) + \int_{\partial \Omega} \partial_\nu G_0(x, y)\varphi(y) \, d\sigma(y), \quad x \in \partial \Omega.
\]

Note that \( W[\varphi] \) is harmonic in \( \Omega \) and the Dirichlet boundary value problem for the Laplace equation in \( \Omega \) is uniquely solvable. Then, by the compactness of

\[
Y^* \ni \varphi \mapsto \int_{\partial \Omega} \partial_\nu G_0(x, y)\varphi(y) \, d\sigma(y) \in Y^*
\]

and the Fredholm alternative, there is a unique solution \( \varphi \in Y^* \) satisfying the boundary integral equation

\[
W[\varphi](x) = \hat{\zeta}(x), \quad x \in \partial \Omega,
\]

and \( \varphi \) depends continuously on \( \hat{\zeta} \in Y^* \). By \( w = 0 \) on \( \partial \Omega \) and \( w = -v \) on \( \partial D \), we have

\[
\int_{\partial \Omega} W[\varphi](x)\partial_\nu w(x) \, d\sigma(x) = \int_{\partial D} (W[\varphi](x)\partial_\nu w(x) + \partial_\nu W[\varphi](x)v(x)) \, d\sigma(x)
\]

by the Green formula, where \( \nu \) is the unit outer normal on \( \partial D \). This immediately implies (28) and completes the proof. \( \square \)

Now we are ready to start considering the reconstruction of the unknown obstacle \( D \) by the NRT. By Proposition 2, it suffices to consider the indicator function (28) for studying the reconstruction by the NRT. The reconstruction by the NRT is a sampling method to test the test domains using the indicator function defined by (9). Likewise before for the reconstruction by the RT, a test domain \( G \) is called positive or no-response if \( I_{NRT}(G) \) is finite.
Remark 4. The meaning of no-response is as follows. If we mask the obstacle \( D \) by a test domain \( G \) i.e. \( \overline{D} \subset \overline{G} \), then we don’t have any huge response i.e. \( I(G) < \infty \) (see the proof of Theorem 5.1, (i) given later). To make the response zero so that we really have no-response, we need to use the following indicator function \( I_{NRT}'(G) \) defined by
\[
I_{NRT}'(G) := \lim_{\varepsilon \to 0} \sup_{\zeta \in H^{-1/2}(\partial \Omega)} \| (\zeta, \partial \nu) \|_{L^2}.
\]

By replacing \( I_{RT}(\cdot) \) in Theorem 4.1 by \( I_{NRT}(\cdot) \), we have the following reconstruction of an unknown obstacle \( D \) by the NRT.

**Theorem 5.1.** For a test domain \( G \), we have the followings.

(i) \( \overline{D} \subset \overline{G} \Rightarrow I_{NRT}(G) < \infty \).

(ii) Let \( \overline{D} \not\subset \overline{G} \) and assume that the solution \( u \in H^1(\Omega \setminus \overline{D}) \) to the forward problem admits an analytic extension across \( \partial D \) from \( \Omega \setminus \overline{D} \) into the whole \( \overline{D} \setminus G \). Then \( I_{NRT}(G) < \infty \).

(iii) As an additional assumption, we assume that \( \Omega \) and \( G \) are \( C^2 \)-spherical domains, i.e. \( \Omega \) and \( G \) are diffeomorphic to an open ball up to their boundaries. Let \( \overline{D} \not\subset \overline{G} \). If the above \( u \) does not admit an analytic extension across \( \partial D \), then \( I_{NRT}(G) = \infty \).

As a consequence, if \( \Omega \) is a \( C^2 \)-spherical domain and also the above solution \( u \) does not admit an analytic extension across \( \partial D \), then \( \overline{D} \) can be reconstructed as the intersection of all \( \overline{G} \) for positive \( C^2 \)-spherical test domain \( G \).

Before getting into the proof, we would like to emphasize that the proof of this theorem is much more involved than that of Theorem 4.1. Especially proving (iii). The key to prove (iii) is the analytic extension of solutions for the Laplace equation. This can be analyzed by using the following well known lemma given in [22, Lemma 3.2]. The proof of (iii) is almost the same as the proof of Theorem 4.1 in that paper, but we need to adopt the proof there to our situation.

**Lemma 5.2.** Let \( \mathcal{O} \Subset \Omega \) be a domain with \( C^2 \) boundary, and \( \mathcal{O}_e := \Omega \setminus \overline{\mathcal{O}} \). Let \( u \) be analytic in \( \mathcal{O}_e \), and consider the following set associated with the Taylor coefficients of \( u \) at \( z \in \mathcal{O}_e \) with \( \text{dist}(z, \partial \Omega) > \rho \) for some \( \rho > 0 \):
\[
\left\{ a_{\ell}(z) := \sup_{h \in \mathbb{R}^2, |h| = 1} \rho \frac{|(h \cdot \nabla)^{\ell} u(z)|}{\ell!} : \ell \in \mathbb{Z}_+ \right\}.
\]

Define \( T(z; \rho) \) by
\[
T(z; \rho) := \sup_{\ell \in \mathbb{Z}_+} a_{\ell}(z).
\]

Fix \( \rho > 0 \) such that \( \text{dist}(z, \partial \Omega) > \rho \) is satisfied for all \( z \in \mathcal{O}_e \) with \( \text{dist}(z, \partial \Omega) > \eta \) for a fixed small \( \eta > 0 \). Assume that the set \( T(z; \rho) \) is bounded in each neighborhood of \( z' \in \mathcal{O}_e \). Then \( u \) can be extended into an open neighborhood of \( \overline{\mathcal{O}}_e \). In other words, there exists a set \( \mathcal{O}' \) with \( \overline{\mathcal{O}}' \subset \mathcal{O} \) such that \( u \) is extensible into \( \mathcal{O}'_e := \Omega \setminus \overline{\mathcal{O}}' \).

**Remark 5.** From the proof of this lemma given in [22], \( z, z' \in \mathcal{O}_e \) can be taken very close to \( \partial \mathcal{O} \). Hence \( \rho \) can be taken very small.

**Proof of Theorem 5.1.** We first consider the case \( \overline{D} \subset \overline{G} \). Then \( w \) has an analytic extension to \( \Omega \setminus G \) which also implies \( w_+ |_{\partial G} \in H^{1/2}(\partial G) \). Hence by Theorem 2.2,
\[ R[\varphi] = \partial_w w \text{ has a solution } \varphi \in H^{-1/2}(\partial G). \] Then we have
\[
I_{NRT}(G) = \sup_{\zeta \in H^{-1/2}(\partial \Omega), \|R^*\zeta\|_{H^{-1/2}(\partial \Omega)} \leq 1} \left( (\zeta, R[\varphi])_{H^{-1/2}(\partial \Omega)} \right) 
\]
\[
= \sup_{\zeta \in H^{-1/2}(\partial \Omega), \|R^*\zeta\|_{H^{-1/2}(\partial \Omega)} \leq 1} \left( (R^*\zeta, \varphi)_{H^{-1/2}(\partial \Omega)} \right) < \infty.
\]
This proves (i).

Next we prove (ii). By the assumption, \( w \) has an analytic extension to \( \Omega \setminus G \) which also implies \( w|_{\partial G} \in H^{1/2}(\partial G) \). Then we can argue in the same way as (i) from here by using Theorem 2.2 to have \( I_{NRT}(G) < \infty \). This proves (ii).

Our next task is to prove (iii). Assume that \( u \) cannot have an analytic extension across \( \partial D \). Let \( \{G_t\}_{t \in [0,T]} \) be a homotopy, that is \( G_t \) depends continuously on \( t \in [0,T] \) and \( G_0 = \Omega, G_1 = G \), and moreover it satisfies \( G_{t'} \in G_t \) for \( t' < t \), \( t, t' \in [0,T] \) and each \( G_t \) with \( t \in (0,T) \) has the same regularity and topological property as \( G \). As for the existence of such a homotopy see Theorem 6.3 of [12]. Since \( u \) cannot be analytically extended into the set \( \Omega \setminus \bar{G} \), then there must exist a maximal parameter \( t_0 \in (0,1) \) such that \( u \) can be analytically extended into \( \Omega \setminus G_{t_0} \) for any \( t < t_0 \) but not into any \( \Omega \setminus G_t \) for all \( t > t_0 \). Hence, for a given \( \rho > 0 \), there exist \( z_0 \in \Omega \setminus G_{t_0} \) with \( \text{dist}(z_0, \partial \Omega) = \inf_{y \in \partial \Omega} |y - z_0| > \rho \) such that \( T(z; \rho) \) for \( w \) is not bounded in any neighborhood \( V(z_0) \subset \Omega \setminus \bar{G}_{t_0} \) of \( z_0 \). Here note that by Remark 5, we can take \( \rho \) very small. We will fix such a \( \rho \). Put
\[
(33) \quad \rho_0 := \text{dist}(z_0, \bar{G}).
\]
Take \( V(z_0) \) as a subset of a ball \( B_{\rho_0/2}(z_0) \) with radius \( \rho_0/2 \) centered at \( z_0 \). For \( z \in V(z_0), \ell \in \mathbb{Z}_+, h \in \mathbb{R}^3 \) with \( |h| = 1 \), define
\[
(34) \quad \beta(z, \ell, h) := \| (h \cdot \nabla)^\ell \mathcal{G}(\cdot, z) \|_{H^1(G \cup (\Omega \setminus \bar{G}))},
\]
where \( \Omega_\epsilon := \{ x \in \Omega : \text{dist}(x, \partial \Omega) > \epsilon \} \) with a small enough \( \epsilon > 0 \). Then the \( H^1(G) \)-norm of the function
\[
(35) \quad \mathcal{H}(\cdot, z, \ell, h) := \frac{1}{2\sigma \kappa} \beta(z, \ell, h) (h \cdot \nabla)^\ell \mathcal{G}(\cdot, z)
\]
is bounded by \( (2\sigma \kappa)^{-1} \) for \( z \) in \( V(z_0) \), where \( \sigma = \|R^{\ell+}\| \) and \( \kappa > 0 \) is the norm of the trace operator \( H^1(G) \to H^{1/2}(\partial G) \).

Now for any fixed \( z \in V(z_0) \), there exist domains \( M(z) \subset \tilde{M}(z) \) with the following properties:
\begin{enumerate}
\item the boundaries \( \partial M(z), \partial \tilde{M}(z) \) of \( M(z), \tilde{M}(z) \) are \( C^2 \),
\item \( u \) is analytic in \( \Omega \setminus M(z) \),
\item \( z \notin \tilde{M}(z) \),
\item \( \Omega \setminus \tilde{M}(z), \Omega \setminus \tilde{M}(z) \) are connected,
\item \( G \subset M(z) \).
\end{enumerate}

Since \( W \) has a dense range (see Proposition A.3), there exists a sequence \( \varphi_n^{z,\ell,h} \in H^{1/2}(\partial \Omega) \), \( n \in \mathbb{N} \) for each \( z \in V(z_0), \ell \in \mathbb{Z}_+, |h| = 1 \) such that
\[
(36) \quad \| W[\varphi_n^{z,\ell,h}] - \mathcal{H}(\cdot, z, \ell, h) \|_{H^{1/2}(\partial \tilde{M}(z))} \to 0, \quad n \to \infty.
\]
Here note that both \( W[\varphi_n^{z,\ell,h}] \), \( \mathcal{H}(\cdot, z, \ell, h) \) satisfy the Laplace equation in \( \tilde{M}(z) \). Hence by the interior regularity estimate for solutions of the Laplace equation, we
have
\[
\|W[\varphi_{n}^{z,\ell,h}]-\mathcal{H}(\cdot,z,\ell,h)\|_{H^{1}(M(z))} \to 0, \ n \to \infty
\]
and
\[
\|W[\varphi_{n}^{z,\ell,h}]-\mathcal{H}(\cdot,z,\ell,h)\|_{H^{1}(M(z))} \leq (2\sigma\kappa)^{-1}
\]
for large enough \(n = n(z,\ell,h)\) which depends on \(z \in V(z_{0}), \ell \in \mathbb{Z}_{+}, |h| = 1\). From (34), (35), (38) and the above property (5),
\[
\|W[\varphi_{n}^{z,\ell,h}]\|_{H^{1}(G)} \leq \|W[\varphi_{n}^{z,\ell,h}]-\mathcal{H}(\cdot,z,\ell,h)\|_{H^{1}(G)} + \|\mathcal{H}(\cdot,z,\ell,h)\|_{H^{1}(G)} \leq (\sigma\kappa)^{-1}, \ z \in V(z_{0}), \ell \in \mathbb{Z}_{+}, |h| = 1
\]
with \(n = n(z,\ell,h)\). This implies
\[
\|R^{(s)}W[\varphi_{n}^{z,\ell,h}]\|_{H^{1/2}(\partial G)} \leq 1, \ z \in V(z_{0}), \ell \in \mathbb{Z}_{+}, |h| = 1
\]
with \(n = n(z,\ell,h)\).
Now recall (28), and for \(n \in \mathbb{N}\), consider
\[
I_{NRT}^{(n)}(G) := \left| \int_{\partial D} \left( |W[\varphi_{n}^{z,\ell,h}](x)\partial_{\nu}w(x) + \partial_{\nu}W[\varphi_{n}^{z,\ell,h}](x)w(x) \right) d\sigma(x) \right|.
\]
Then by the Green formula, we have
\[
I_{NRT}^{(n)}(G) = \int_{\partial D} \left( |W[\varphi_{n}^{z,\ell,h}](x)\partial_{\nu}w(x) - \partial_{\nu}W[\varphi_{n}^{z,\ell,h}](x)w(x) \right) d\sigma(x)
\]
\[
= \int_{\gamma} \left( |W[\varphi_{n}^{z,\ell,h}](x)\partial_{\nu}w(x) - \partial_{\nu}W[\varphi_{n}^{z,\ell,h}](x)w(x) \right) d\sigma(x),
\]
where \(\gamma = \partial(M(z) \cap D)\) and the normal on \(\gamma\) is pointing into the exterior of the finite region closed by the curve \(\gamma\). Since \(\gamma \subset M(z)\), by taking the limit \(n \to \infty\) to (42) and using (35) and (37), we have
\[
\lim_{n \to \infty} I_{NRT}^{(n)}(G) = \int_{\gamma} \left( \frac{\partial w(x)}{\partial \nu}(x)\mathcal{H}(x,z,\ell,h) - \partial\mathcal{H}(x,z,\ell,h)\mathcal{G}(x,z) \right) d\sigma(x)
\]
\[
= \frac{1}{\beta(z,\ell,h)} \int_{\gamma} \left( \frac{\partial w(x)}{\partial \nu}(x)(h \cdot \nabla)^{\ell}\mathcal{G}(x,z) - \partial_{\nu}\mathcal{G}(x,z) \right) d\sigma(x)
\]
\[
= \frac{1}{\beta(z,\ell,h)(h \cdot \nabla)^{\ell}w_{ext}(z)} - \frac{1}{4\beta(z,\ell,h)}(h \cdot \nabla)^{\ell}w_{ext}(z),
\]
where
\[
w_{ext}(z) := \int_{\delta \Omega} \left( \frac{\partial w(y)}{\partial \nu}(y)\mathcal{G}(y,z) - \partial\mathcal{G}(y,z)\mathcal{G}(y,z) w(y) \right) d\sigma(y).
\]
Now recall that \(T(z;\rho)\) for \(w\) is not bounded in \(V(z_{0})\). Hence, for any \(k \in \mathbb{N}\), there exist \(z_{k} \in V(z_{0}), \ell_{k} \in \mathbb{Z}_{+}\) and a unit vector \(h_{k} \in \mathbb{R}^{3}\) such that
\[
\left| \frac{\partial w_{ext}(z_{k})}{\partial \psi_{k}^{\ell}}(h_{k} \cdot \nabla)^{\ell}w(z_{k}) \right| \geq k.
\]
On the other hand, by the analyticity of $G(y, z)$ with respect to $z \in V(z_0)$ for $y \in G \cup (\Omega \setminus \Omega_\epsilon)$, there exists a constant $c > 0$ such that
\[
|\beta(z, \ell, h)| \leq c \frac{\ell}{\rho^\ell}, \quad z \in V(z_0), \; \ell \in \mathbb{Z}_+, \; |h| = 1.
\]
This follows from (34) and $G(\cdot, z)$ in $G \cup (\Omega \setminus \Omega_\epsilon)$ satisfies a similar estimate as (46).

Further, from the definition (34) of $\beta(z, \ell, h)$ and the definition (44) of $w_{\text{ext}}$, we have
\[
\left| \frac{1}{\beta(z, \ell, h)}(h \cdot \nabla)^\ell w_{\text{ext}}(z) \right| \leq c', \quad z \in V(z_0), \; \ell \in \mathbb{Z}_+, \; |h| = 1
\]
for some constant $c' > 0$. Hence combining (43)–(47), we have
\[
I_{\text{NRT}}^{(n_k)}(G) = \lim_{k \to \infty} I_{\text{NRT}}^{(n_k)}(G) = \infty.
\]
Here we remark that $\varphi_k$ satisfies (40) so that we can have the above inequality in the estimate (47). This completes the proof of (iii). The rest of the proof is the same as that for Theorem 4.1.

Remark 6. We could have defined the indicator function $I_{\text{NRT}}(G)$ for a test domain $G$ as
\[
I_{\text{NRT}}^{(n_k)}(G) = \lim_{k \to \infty} I_{\text{NRT}}^{(n_k)}(G) = \infty.
\]
Then we can say the same as before in Remark 3.

6. Convex polygonal $D$. In this section we will provide a proof of Theorem 1.3.

Concerning the analytic extension of $u$ across $\partial D$ we have the following proposition.

Proposition 3. Let $D$ be a convex polygon. Assume that $D$ satisfies one of the following conditions.

(i) All the corners of $D$ have irrational angles.
(ii) $D$ satisfies the distance property (2).

Then $u$ cannot analytically extend across this corner.
Proof. This can be easily proved along the same way following the proofs for Lemma 3.1 and Lemma 3.2 in [9]. More precisely consider the function $u^e(x)$ in the proof of Lemma 3.1 of [9] which satisfies the Dirichlet boundary condition on $P_1 \cap P_2 \cap B_r(a_0)$ and assume that it can be analytically extended across $a_0$ into $D$. Then our task is to show that this implies $f \equiv 0$ which contradicts to $f \not\equiv 0$. Here $P_1, P_2$ are half spaces such that their intersection generates a sector which locally gives a corner of $D$ at its vertex $a_0$. This $w^e$ corresponds to our $u$. Then $u$ becomes

$$u(x) = \sum_{k=1}^{\infty} b_k^e r^k \sin(k\varphi), \; x \in B_r(a_0)$$

with small $\epsilon > 0$ and $b_k^e \sin(k\alpha) = 0$, $k \in \mathbb{N}$, where $B_r(a_0) := \{ |x - a_0| < \epsilon \}$. Here we have

$$\begin{align*}
\text{case 1:} & \quad \sin(k\alpha) \neq 0, \; k \in \mathbb{N} \text{ if } \alpha/\pi \not\in \mathbb{Q} \implies b_k^e = 0, \; k \in \mathbb{N}, \\
\text{case 2:} & \quad \sin(k\alpha) = 0, \; k \in \mathbb{N} \text{ if } \alpha/\pi = q/p \in \mathbb{Q} \\
& \quad \text{with } p, q \in \mathbb{N}, \; (p, q) = 1, \; p|k,
\end{align*}$$

(50)

where $p|k$ and $(p, q) = 1$ mean that $p$ is a divisor of $k$ and $p, q$ do not have any common divisor, respectively. We have the case 1 for (i) in the theorem, and we have to consider both the cases 1 and 2 for (ii) in the theorem. For the case (i), $u = 0$ in $B_r(a_0) \cap (\Omega \setminus D)$. Hence we have $f = u|_{a_0} \equiv 0$ by the UCP which contradicts to $f \not\equiv 0$. For the case 2, note that we have $k = mp, m \in \mathbb{N}$. Then arguing as in [9] using the rotations around $a_0$ by angle $2\pi/p$ and the distance condition which allows us to have $r > 0$ such that $\overline{D} \subset B_r(a_0) \subset \Omega$, $u$ can be analytically continued inside the whole $B_r(a_0)$. Hence $u$ satisfies the homogeneous Dirichlet boundary value problem in $D$ for the Laplace equation, which yields $u = 0$ in $D$. Then the UCP implies $f \equiv 0$ which contradicts to $f \not\equiv 0$.\]

We will first show Theorem 1.3 by using the RT.

**Theorem 6.2.** Let $D$ be the same as in Proposition 3. Let $G$ be a convex polygonal test domain. Then we have the followings.

(i) $\overline{D} \subset \overline{G} \implies I_{RT}(G) < \infty$.

(ii) $\overline{D} \nsubseteq \overline{G} \implies I_{RT}(G) = \infty$.

As a consequence we have the following reconstruction of $\overline{D}$ as $\overline{D} = \cap_{G \in \mathcal{P}} \overline{G}$.

Proof. (i) can be proved in the same way as that of Theorem 4.1. If $\overline{D} \nsubseteq \overline{G}$, there is at least one vertex of $D$ lying outside of $\overline{G}$. Then by using Proposition 3, we easily have $I_{RT}(G) = \infty$.\]

Finally we show Theorem 1.3 by using NRT.

**Theorem 6.3.** Assume the existence of a priori convex polygon $D_0$. Let $D$ be the same as in Proposition 3 and let $G \subset D_0$ be a convex polygonal test domain. Then we have the followings.

(i) $\overline{D} \subset \overline{G} \implies I_{NRT}(G) < \infty$.

(ii) $\overline{D} \nsubseteq \overline{G} \implies I_{NRT}(G) = \infty$.

As a consequence we have the following reconstruction of $\overline{D}$ as $\overline{D} = \cap_{G \in \mathcal{P}} \overline{G}$, where $\mathcal{P}$ denotes the set of all positive test convex polygonal test domain $G \subset D_0$.\]

**Inverse Problems and Imaging** Volume 15, No. 2 (2021), 367–386
Proof. The proof of (i) is the same as that of (i) in Theorem 5.1. Also by considering the homotopy \{G_t\}_{t \in [0, 1]} such that \(G_0 = D_0, G_1 = G\) and each \(G_t\) is a convex polygon, we can just repeat the proof of (iii) in Theorem 5.1 to prove (ii).

Appendix. In this appendix we will give the proofs of the bijectivity of \(S\), the denseness of the ranges of operators \(R^*\) and \(W\). We give unified proofs which are valid for both the two dimensional case and the three dimensional case. We first prove the bijectivity of \(S\).

Proposition A.1. The operator
\[ S : H^{-1/2}(\partial G) \to H^{1/2}(\partial G) \text{ is bijective.} \]

Proof. Decompose \(S\) into
\[ S = S_0 + S_1, \]
where \(S_0\) is the operator defined likewise the operator \(S\) by the potential
\[
\begin{aligned}
&\frac{1}{4\pi|x-y|} \quad \text{if } n = 3, \\
&-\frac{1}{2\pi} \log |x-y| \quad \text{if } n = 2,
\end{aligned}
\]
for \(x \neq y\). Then it is well known that \(S_0 : H^{-1/2}(\partial G) \to H^{1/2}(\partial G)\) is a Fredholm operator with index 0 (see [18]) and \(S_1 : H^{-1/2}(\partial G) \to H^{1/2}(\partial G)\) is compact. We remark here that \(S_0\) is even bijective for \(n = 3\). Hence \(S\) is a Fredholm operator with index 0. Then by the Fredholm alternative we only need to show \(S\) is injective. That is
\[
\varphi \in H^{-1/2}(\partial G) \implies \varphi = 0,
\]
where \(v_+ = S[\varphi]|_{\Omega \setminus G}\). Observe that we have
\[
\begin{aligned}
\Delta v_+ &= 0 \quad \text{in } \Omega \setminus G, \\
v_+ &= 0 \quad \text{on } \partial \Omega, \\
v_+ &= 0 \quad \text{on } \partial G.
\end{aligned}
\]
By the uniqueness of this boundary value problem, we have \(v_+ = 0\) in \(\overline{\Omega \setminus G}\). On the other hand \(v_- := S[\varphi]|_G\) satisfies
\[
\begin{aligned}
\Delta v_- &= 0 \quad \text{in } G, \\
v_- &= v_+ = 0 \quad \text{on } \partial G,
\end{aligned}
\]
which implies \(v_- = 0\) in \(\overline{G}\). Then by the jump formula for \(\partial \nu S[\varphi] \) at \(\partial G\), we have \(\varphi = 0\). Here note that the singularity of the kernels of \(S\) and \(S_0\) are the same at \(\partial G\).

Next we will prove the denseness of the ranges of the operators \(R^*\) and \(W\). Since the proofs are almost the same, we only give the details for \(R^*\) and just point out some additional things to be concerned for \(W\).

Proposition A.2. \(R^*\) is injective. Hence the range \(\text{Rge}(R^*) \subset H^{-1/2}(\partial G)\) of \(R^*\) is dense.
Proof. It is well known that we have $\overline{\text{Rge}(R^*)} = N(R)^\perp$, where $N(R)$ is the kernel of $R$. Hence it is enough to prove the injectivity of $R$. To show this let $\varphi \in H^{-1/2}(\partial G), R\varphi = 0$ on $\partial \Omega$. Put

$$ q(x) := \int_{\partial G} \partial_{\nu_y} G(x, y) \varphi(y) \, d\sigma(y), \quad x \in \Omega \setminus \partial G, $$

then $q$ satisfies

$$ \begin{cases} 
\Delta q = 0 & \text{in } \mathbb{R}^n \setminus \partial G, \\
q = 0 & \text{on } \partial \Omega, \\
q(x) = O(|x|^{-(n-1)}), \nabla q(x) = O(|x|^{-n}) & \text{as } |x| \to \infty.
\end{cases} $$

(A.2)

By the uniqueness of the exterior problem (see Chapter 8 of [19]), we have

$$ \begin{align*}
q = 0 \quad &\text{in } \mathbb{R}^n \setminus \Omega \\
\partial_{\nu_y} q = 0 \quad &\text{on } \partial \Omega. 
\end{align*} $$

and this implies $\partial_{\nu_y} q = 0$ on $\partial \Omega$. Here note that we have one order faster decay for $q(x)$ and $\nabla q(x)$, but the order given in (A.2) is enough to have (A.3). Then by the UCP, we have $q = 0$ in $\mathbb{R}^n \setminus \overline{G}$ and this implies $(\partial_{\nu_y} q)|_{\partial G} = 0$. By the continuity of the normal derivative of $q$ at $\partial G$, we have the trace of the normal derivative $(\partial_{\nu_y} q)|_{\partial G}$ taken from $G$ is zero, i.e. $(\partial_{\nu_y} q)|_{\partial G} = 0$. Recalling $\Delta q = 0$ in $G$, there exists a constant $c$ such that $q = c$ on $\overline{G}$. Hence by the jump formula, $\varphi = c$, and hence

$$ q(x) = c \int_{\partial G} \partial_{\nu_y} G(x, y) \, d\sigma(y), \quad x \in \mathbb{R}^n \setminus \partial G. $$

This contradicts to $q = 0$ in $\mathbb{R}^3 \setminus \overline{\Omega}$ if $c \neq 0$. Hence $c$ must be zero and hence $\varphi = 0$. Thus we have proven the injectivity of $R$. \hfill \Box

Proposition A.3. Consider the layer potential operator $W$ defined by (26) as an operator $W : H^{1/2}(\partial \Omega) \to H^{1/2}(\partial \tilde{M}(z))$. Then the range $\text{Rge}(W) \subset H^{1/2}(\partial \tilde{M}(z))$ of $W$ is dense.

Proof. As mentioned before the proof is quite similar to the proof of Theorem A.2. Hence we will only point out some additional things necessary for proving the denseness of $\text{Rge}(W)$. In order to simplify the notations in this proof we denote $X := H^{-1/2}(\partial \tilde{M}(z)), Y := H^{-1/2}(\partial \Omega)$ and their dual spaces by $X^* = H^{1/2}(\partial \tilde{M}(z))$ and $Y^* = H^{1/2}(\partial \Omega)$, respectively. Also let $J_X : X \to X^*$ and $J_Y : Y \to Y^*$ be the isometric isomorphisms. Let $W^* : X^* \to Y^*$ and $W^{(*)} : X \to Y$ be the adjoint operator and dual operator of $W$. Then since $W^* = J_Y W^{(*)} J_X^{-1}$, it is enough to prove $W^{(*)}$ is injective. By a direct computation, $W^{(*)}$ is given as

$$ W^{(*)}[\psi](y) = \int_{\partial G} \partial_{\nu_y} G(x, y) \psi(x) \, d\sigma(x), \quad y \in \partial \Omega $$

for any $\psi \in X$. Further, by the denseness of $X^* \subset X$ and the continuity of $W^{(*)}$, it is enough to prove that if $\psi \in X^*$, $W^{(*)}[\psi](y) = 0, y \in \partial \Omega$, then $\psi = 0$. The rest of the proof is almost the same as that of Proposition A.2. \hfill \Box

Acknowledgments. We thank the anonymous referees for their useful comments for improving this paper. The second author appreciate Professor Guanghui Hu at Beijing Computational Science Research Center for several useful discussions. For the research funds, the first author, the second author and the fourth author acknowledge their supports from the Ministry of Science and Technology Taiwan, under the Columbus Program: MOST-109-2636-M-009-006, the Grant-in-Aid for
Scientific Research 19K03554 and 15H05740 of JSPS and the National Natural Science Foundation of China (Nos.11671082, 12071072), respectively.
