Abstract:

Background: Gastrointestinal tract perforation is one of the common surgical emergency all over the world. Menekse et al devised POMPP score (predictive score of mortality in perforated peptic ulcer) to predict the morbidity and mortality in peptic ulcer perforation. Aim: The objective of this study was to assess the validity of POMPP score in peptic ulcer perforation and to assess its usefulness in gastrointestinal perforation due to causes other than the peptic ulcer. Methods: Fifty consecutive cases, who had undergone exploratory laparotomy for gastrointestinal perforation peritonitis, were included in the study. “These patients were assessed at the time of admission on the basis of Age >65 years, BUN >45mg/dl (Blood Urea Nitrogen) and Albumin <1.5g/L and a score of 1 point each had been given”. The total score was compared with the outcome of the disease in relation with mortality. Results: In our study, 42% of gastrointestinal perforation were due to peptic ulcer, 22 % due to small bowel perforations (18% Ileal and 4 % Jejunal), 14 % due to trauma and 22 % due to miscellaneous causes. Morbidity is common after gastrointestinal perforation and it ranges from 17-63% whereas mortality ranges from 6-14%. Conclusions: POMPP score is easy and valid scoring system for peptic ulcer perforation. Early detection of high risk peptic perforation cases, allow other supportive treatment modality apart from surgery which can decrease the mortality. However, this score is not valid in perforation due to causes other than peptic ulcer.

Keywords: Gastrointestinal tract perforation, POMPP score, Peptic ulcer perforation scoring

Introduction

Gastrointestinal tract perforation is one of the common surgical emergency all over the world. The spectrum of aetiology of gastrointestinal perforation in India is different from the western world.¹ It is one of the common cause of morbidity and mortality in adults. Duodenal ulcer perforations are 2-3 times more common than gastric ulcer perforation. In one third of patients, gastric ulcer perforation is due to gastric carcinoma. There is advancement in the surgical technique, intensive care support and antimicrobial therapy but still surgery for gastrointestinal perforation is difficult and complex.

Menekse et al, devised POMPP score (predictive score of mortality in perforated peptic ulcer) to predict the morbidity and mortality in peptic ulcer perforation.²

Aim

This study is aimed to assess the validity of previously derived POMPP score in peptic ulcer perforation by Menekse et al and also to assess its usefulness in other gastrointestinal perforation.

Methods

This is a prospective study conducted at Government Medical College, Amritsar, Punjab, India from May 2016 to April 2017. Informed consent form was obtained from all participants included in the study. Fifty consecutive cases, who had undergone exploratory laparotomy for gastrointestinal perforation peritonitis, were included in the study. “These patients were assessed at the time of admission on the basis of Age >65 years, BUN >45mg/dl (Blood Urea Nitrogen) and Albumin <1.5g/L and a score of 1 point each had been given”². The total score was between 0-3 and maximum score was 3. The total score was compared with the outcome of the disease in relation with mortality. The death that occurred within 30 days of continued hospital admission after surgical treatment or death at the same admission had been included as hospital mortality. Perforation due to malignancy were excluded from the study.
Results

50 consecutive cases of gastrointestinal perforation were enrolled for the study. All these patients were assessed on the basis of age, preoperative BUN and serum albumin. Table 1 is showing different types of perforation which were enrolled in the study. There were 44 males and 6 female cases. POMPP scoring was done in all the patients. Morbidity, like local complication (surgical site infection, wound dehiscence, entero-cutaneous fistula and pelvic abscess), and systemic complication (like respiratory, cardiac and renal complications) and mortality assessed as per the Table 2-5.

Table 1: Different sites of perforation (n=50).

| Site of perforation                                      | No. of cases | M  | F  |
|---------------------------------------------------------|--------------|----|----|
| Peptic ulcer perforation (duodenal)                     | 11           | 10 | 1  |
| Peptic ulcer perforation (gastric)                      | 10           | 10 | 0  |
| Appendicular perforation                                | 03           | 3  | 0  |
| Ileal perforation                                       | 09           | 7  | 2  |
| Jejunal perforation                                     | 02           | 2  | 0  |
| Caecal, colonic perforation and rectal                  | 05           | 4  | 1  |
| Gall bladder                                            | 03           | 2  | 1  |
| Trauma (blunt/penetrating)                              | 07           | 6  | 1  |

There were 21 cases of peptic ulcer perforation (42%) as shown in Table 2. Graham’s omental patch repair was done in all the cases. Out of these 21, 9 cases had zero score. No morbidity and mortality occurred in these patients.

Table 2: Peptic ulcer perforation (duodenal +gastric) n= 21.

| Local complication | Respiratory | Cardiac | Renal | Mortality |
|--------------------|-------------|---------|-------|-----------|
| Score              | N | SSI | WD | Others | ECF | URTI | ARDS | AF | BRAD | ARF | UTI |             |
| 0                  | 9 | -   | -  | -      | -   | -    | -    | -  | -    | -   | -   | 1          |
| 1                  | 9 | 3   | 2  | -      | -   | 1    | -    | -  | -    | -   | -   | 1          |
| 2                  | 2 | 1   | -  | -      | 1   | 1    | -    | -  | -    | -   | -   | 1          |
| 3                  | 1 | -   | -  | -      | -   | 1    | 1    | -  | -    | -   | -   | 1          |

N - Number, SSI- Surgical Site Infection, WD- Wound Dehiscence, ECF-Entero Cutaneous Fistula, RESP- Respiratory, URTI-Upper Respiratory Tract Infection, ARDS- Acute Respiratory Distress Syndrome, AF-Atrial Fibrillation, Brad-Bradycardia, ARF-Acute Renal Failure, UTI-Urinary Tract Infection, PA-Pelvic Abscess.

Score 1 was found in 9 cases. Among these, 3 developed SSI, 2 had wound dehiscence and 1 developed respiratory and renal complication. There were two cases of score 2. One of them developed entero-cutaneous fistula. No mortality was found in score 1 and 2. Some cases had multiple local and systemic complications. There was 1 mortality with score 3. (Table 2).

Table 3: Jejunal and Ileal perforation (n=11).

| Local complication | Respiratory | Cardiac | Renal | Mortality |
|--------------------|-------------|---------|-------|-----------|
| Score              | N | SSI | WD | Others | ECF | URTI | ARDS | AF | BRAD | ARF | UTI |             |
| 0                  | 5 | 2   | 1  | -      | -   | -    | -    | -  | -    | -   | -   | 1          |

| 3                  | - | -   | -  | -      | -   | -    | -    | -  | -    | -   | -   | -          |

This result validates the POMPP score in peptic ulcer perforation.

There were 11 cases of Jejunal and Ileal perforation (22% together). Two of the Ileal perforation were due to tuberculosis with stricture and 7 cases of Ileal perforation were due to enteric fever. Jejunal perforation were due to nonspecific inflammation on histopathological examination (HPE). Segmental resection and end to end hand sewen anastomosis was done in tuberculous Ileal perforation with stricture. Primary repair was done in all other Ileal and Jejunal perforation. Local and systemic complication were found as shown in Table 3. There was 1 mortality in score 0 and 3 mortalities in score 1.
Indexcopernicus value - 64.48

Discussion

Gastrointestinal perforation is frequently encountered surgical emergency in tropical countries like India than western country. [1] Traumatic injury to the stomach and duodenum is rare. [2] Morbidity is common after gastrointestinal perforation from 17-63% whereas mortality ranges from 6-14%. [3-5] Main etiologic factors for peptic ulcer perforation are use of non-steroidal anti-inflammatory drugs (NSAIDs), steroids, smoking, Helicobacter pylori and a diet high in salt. [3,6] All these factors affect the acid secretion in the gastric mucosa. In India, the small bowel is the next common site of spontaneous perforation after peptic ulcer perforation as shown in our study. Most small intestinal perforations occur in the distal ileum. This is due to prevalence of enteric fever and tuberculosis in this region and this was the main etiological factor in small intestinal perforation. “Hypoalbuminemia was one of the major factor associated with increased mortality. [7,8] Age over 65 years is an independent risk factor for mortality. [9,10] BUN level is regulated as a result of several conditions such as protein catabolism, steroid intake and gastrointestinal bleeding. Regardless of renal functions, it is also accepted as a marker of a severity of disease”. [11] In this study, 42% of gastrointestinal perforation were due to peptic ulcer, 22% due to small bowel perforations (18% ileal and 4% Jejunal), 14% due to trauma and 22% due to miscellaneous causes.

In this study, POMPP score was found to be very practical and easy. But it was valid only in peptic ulcer perforation.

Conclusion

POMPP score is easy and valid scoring system for peptic ulcer perforation. Early detection of high risk peptic perforation cases, allow other supportive treatment modality apart from surgery which can decrease the mortality. However, this score is not valid in perforation due to causes other than peptic ulcer.
