A geometric view of the possible outcomes of elastic collisions of two massive bodies is developed that integrates laboratory, center of mass, and relative body frames in a single diagram. From these diagrams all the scattering properties of binary collisions can be obtained. The particular case of gravitational scattering by a moving massive object corresponds to the slingshot maneuver, and its maximum velocity is obtained.

I. INTRODUCTION

We show how to geometrically parametrize the elastic collision between two bodies of arbitrary masses and velocities by using diagrams in the rest-frame of one of the bodies. For given masses and initial velocities the possible solutions in two dimensions can be parametrized by a single angle $\theta$ for both attractive or repulsive interactions. Although an elastic collision is an highly idealized approximation of real interactions, there are many applications where this approximation is appropriate.

The statement that two bodies collide means that for a very short time $\delta t$ in comparison to the ratio of characteristic length scales and speeds, the forces due to gravitational, electromagnetic, or any other interaction between the two bodies dominate any external forces in causing the momentum change $\Delta \vec{p}$ of each of the bodies. This condition implies that the impulse received from the external forces by one body during the collision is negligible in comparison to the impulse contribution from the interaction forces due to the other body, which usually justifies assuming that the total linear momentum or center of mass momentum of the two bodies during the collision is a constant. This assumption is an approximation because the total change of momentum of the system is equal to the total impulse received. (The total impulse due to internal forces must add to zero because the forces on the two bodies must be instantaneously equal and opposite.) This approximation becomes better as $\delta t \to 0$ or the external forces become weaker relative to the internal forces and is exact when there are no external forces in which case the center of mass momentum is a constant of the motion.

When the interactions are conservative, the total mechanical energy is conserved during the collision, which leads to the assumption that the total kinetic energy is conserved immediately before and after the collision, that is, when the internal forces are (and again become) negligible in comparison to the external forces. This assumption is also an approximation, which becomes asymptotically exact when there are no external forces. When the internal forces are central, the total angular momentum is also conserved in the collision under similar assumptions.

The usual treatment of the elastic collision of two bodies of masses $m_1$ and $m_2$ with initial velocities $\vec{v}_0$ and $\vec{u}_0$ invokes conservation of linear momentum and kinetic energy in a one- or two-dimensional setting. Three-dimensional collisions are seldom addressed, but see Ref. 4.

![FIG. 1: Laboratory and CM views of an elastic collision between two bodies](image)

The view from the initial (rest) frame of one of the bodies is usually worked out and related to the center of mass (CM) view of the collision. The latter is particularly simple because the total linear momentum $\vec{P}_{cm}$ is always
zero in this reference frame, which means that
\[ \mathbf{v}_0' = -\frac{m_2}{m_1} \mathbf{u}_0' \quad \text{and} \quad \mathbf{v}_1' = -\frac{m_2}{m_1} \mathbf{u}_1', \]
where \( \mathbf{v}_i' = \mathbf{v}_i - \mathbf{V}_{cm} \) and \( \mathbf{u}_i' = \mathbf{u}_i - \mathbf{V}_{cm} \). Equation (1) means that the incoming velocities appear as collinear opposing vectors in the CM frame and so do the outgoing velocities. Conservation of kinetic energy is a scalar equation which in the CM frame can be expressed as
\[ |\mathbf{v}_0'| = |\mathbf{v}_1'| \quad \text{and} \quad |\mathbf{u}_0'| = |\mathbf{u}_1'|. \] (2)

The resulting velocity directions remain undefined, so additional information is necessary to completely determine the velocities, for example, the scattering angle with respect to a reference direction. For a vector of given magnitude but unknown direction the possible outcomes define the points on a circumference centered on the origin. In the CM frame these vectors, \( \mathbf{v}_1' \) and \( \mathbf{u}_1' \), describe two circumferences whose diametrically opposed points represent the possible outcomes for the \( v \)-body and \( u \)-body velocities (see Fig. 1). To return to the laboratory frame it is necessary to add the constant vector \( \mathbf{V}_{cm} \).

In the laboratory frame the following procedure can be used to geometrically determine these outcomes. First notice that \( \mathbf{v}_1 = \mathbf{v}_0 \) and \( \mathbf{u}_1 = \mathbf{0} \) is also a possible solution, corresponding to a missed collision. Extending \( \mathbf{v}_0 \) and \( \mathbf{u}_0 \) from the origin defines points on two concentric circumferences whose center is pointed to by extending \( \mathbf{V}_{cm} \) from the origin; these three points are in a straight line. These two circumferences define all the possible velocities in the laboratory frame, and once the direction of a resulting velocity is determined, then so is the other by the collinearity of the three points (two on each circumference plus the center). The collision trapezoid in velocity space referred to in many textbooks is obtained in Fig. 1 by joining all the arrowheads.

These properties of the binary elastic collision are well known and will not be discussed further. Instead, we will develop an alternative geometric interpretation of the conservation laws and relate the laboratory view, the CM view, and the view of the collision from the initial reference frame of one of the bodies. This latter reference frame is more practical because it is asymptotically coincident at \( t \to -\infty \) with the non-inertial body frame of the relative coordinates and velocities for which the two-body problem for central forces is usually solved; that is, the frame in which the relative motion of the two masses will appear as that of a single reduced mass \( \mu = m_1 m_2/(m_1 + m_2) \), at the relative position of one of the masses, moving under forces pointing to a fixed total mass \( M = m_1 + m_2 \) at the frame’s origin, where the other mass is at rest; this motion can be calculated for sufficiently well behaved forces. In particular, for a gravitational collision the result must be a hyperbola (unless the asymptotic provisos made in the preceding paragraphs do not apply, for example if the two bodies do not start or end sufficiently far apart, and then elliptic and parabolic collisions should be considered).

II. ELASTIC COLLISION: TWO-DIMENSIONAL CASE WITH ONE BODY AT REST

In a collision with a mass at rest at the origin, the resulting trajectories lie on a plane in which the total angular momentum \( \mathbf{L}_0 \) relative to the CM is orthogonal to both \( \mathbf{v}_1 \) and \( \mathbf{u}_1 \) (strong action-reaction law).

In the frame where the \( u \)-body is initially at rest, the relevant conservation equations for a collision with a \( v \)-body with velocity \( \mathbf{v}_0 \) are
\[ m_1 \mathbf{v}_0 = m_1 \mathbf{v}_1 + m_2 \mathbf{u}_1, \] (3a)
\[ \frac{1}{2} m_1 v_0^2 = \frac{1}{2} m_1 v_1^2 + \frac{1}{2} m_2 u_1^2, \] (3b)
which represent linear momentum conservation and kinetic energy conservation before and after an elastic collision. An equivalent way of writing Eq. (3) is
\[ \frac{m_1}{m_2} (\mathbf{v}_0 - \mathbf{v}_1) = \mathbf{u}_1 \] (4a)
\[ \frac{m_1}{m_2} (\mathbf{v}_0 - \mathbf{v}_1) \cdot (\mathbf{v}_0 + \mathbf{v}_1) = \mathbf{u}_1 \cdot \mathbf{u}_1. \] (4b)

We use Eq. (4a) to replace \( m_1 (\mathbf{v}_0 - \mathbf{v}_1)/m_2 \) by \( \mathbf{u}_1 \) on the left-hand side of Eq. (4b), and \( \mathbf{u}_1 \) by \( m_1 (\mathbf{v}_0 - \mathbf{v}_1)/m_2 \) on the right-hand side and obtain
\[ \mathbf{u}_1 \cdot (\mathbf{v}_0 + \mathbf{v}_1) = \mathbf{u}_1 \cdot \left( \frac{m_1}{m_2} (\mathbf{v}_0 - \mathbf{v}_1) \right). \] (5)

Equation (5) can be solved to express the unknown scalar product \( \mathbf{v}_1 \cdot \mathbf{u}_1 \) in terms of \( \mathbf{v}_0 \cdot \mathbf{u}_1 \) as
\[ \mathbf{v}_1 \cdot \mathbf{u}_1 = \frac{m_1 - m_2}{m_1 + m_2} \mathbf{v}_0 \cdot \mathbf{u}_1. \] (6)

We take the scalar product of \( \mathbf{u}_1 \) with both sides of Eq. (4b) and use Eq. (5) to eliminate \( \mathbf{v}_1 \cdot \mathbf{u}_1 \) and obtain
\[ \frac{2 m_1}{m_1 + m_2} \mathbf{v}_0 \cdot \mathbf{u}_1 = \mathbf{u}_1 \cdot \mathbf{u}_1. \] (7)

Equation (7) expresses the magnitude
\[ u_1 = |\mathbf{u}_1| = \sqrt{\mathbf{u}_1 \cdot \mathbf{u}_1} \] (8)
in terms of the unknown angle \( \theta \) that \( \mathbf{u}_1 \) makes with \( \mathbf{v}_0 \). We denote the outgoing direction of the \( u \)-body by
\[ \mathbf{u}_0 = \frac{\mathbf{u}_1}{u_1}. \] (9)

Then Eq. (7) is equivalent to
\[ u_1 = \frac{2 m_1}{m_1 + m_2} \mathbf{v}_0 \cdot \mathbf{u}_0. \] (10)

Apart from the unknown value of \( \theta \), the resulting \( u \)-body velocity must be
\[ \mathbf{u}_1 = \frac{2 m_1}{m_1 + m_2} v_0 \cos(\theta) \mathbf{u}_0. \] (11)
Equation (13) is not particularly illuminating with regard to its geometrical relation to \( \mathbf { u }_1 \), so a more geometrical approach will be adopted in Sec. II A for the determination of \( \mathbf { v }_1 \).

A. Geometrical view

Equation (7) can be expressed in terms of the known vector \( \mathbf { V }_{cm} \). We set

\[
\mathbf { d } = \frac { 2 m_1 } { m_1 + m_2 } \mathbf { v }_0 = 2 \mathbf { V }_{cm},
\]

and collect terms on the left-hand side using the fact that

\[
(\mathbf { d } - \mathbf { u }_1) \cdot \mathbf { u }_1 = 0,
\]

that is, \( \mathbf { d } - \mathbf { u }_1 \) is always orthogonal to \( \mathbf { u }_1 \). Equation (15) shows that any admissible solution \( \mathbf { u }_1 \) will define a chord from the origin to a point on the circumference with fixed diameter defined by \( \mathbf { d } \) (see Fig. 2).

The angle \( \theta \in [ - \pi / 2, \pi / 2 ] \) formed by \( \mathbf { u }_1 \) and \( \mathbf { v }_0 \) is the same as the angle between \( \mathbf { u }_1 \) and \( \mathbf { d } \). Thus, \( \mathbf { u }_\theta \) is the unit vector in the direction determined by \( \theta \), and for a given choice of \( \theta \),

\[
\mathbf { u }_1 = d \cos ( \theta ) \mathbf { u }_\theta.
\]  

Given the geometric constraints on \( \mathbf { u }_1 \), we can determine \( \mathbf { v }_1 \) by substituting \( m_1 ( \mathbf { v }_0 - \mathbf { v }_1 ) / m_2 \) for \( \mathbf { u }_1 \) on the left-hand side of Eq. (13). After rearranging terms we obtain

\[
\mathbf { u }_1 \cdot ( \mathbf { v }_0 + \mathbf { v }_1 - \mathbf { u }_1 ) = 0.
\]

Equation (17) means that the vector \( \mathbf { n } \) given by

\[
\mathbf { n } = \mathbf { v }_0 + \mathbf { v }_1 - \mathbf { u }_1,
\]

is always orthogonal to \( \mathbf { u }_1 \),

\[
\mathbf { u }_1 \cdot \mathbf { n } = 0.
\]

We will show now that, just like \( \mathbf { u }_1 \), the vector \( \mathbf { n } \) is uniquely determined as soon as \( \theta \) is given. The expression for \( \mathbf { v }_1 \) will then also be determined from Eq. (15) as

\[
\mathbf { v }_1 = \mathbf { u }_1 - \mathbf { v }_0 + \mathbf { n }.
\]  

We use the orthogonality condition expressed by Eq. (19) to cancel the right-hand side in the scalar prod-
The possible outcomes of $\vec{v}_1$ are defined by a circumference centered at $\vec{D}$ away from the origin, with radius $d = 2\vec{v}_0$. FIG. 3: Collision diagram for equal masses $m_1 = m_2$, with the $u$-body (mass $m_2$) at rest ($\vec{u}_0 = 0$). The $\vec{u}_1$ and $\vec{v}_1$ circumferences now coincide, and necessarily $\vec{v}_1 \parallel \vec{n} \perp \vec{u}_1$, that is $\theta + \varphi = \frac{\pi}{2}$.

The product of Eq. (16) with $\vec{n}$, and replace Eq. (20) on its left-hand side to find $(m_1/m_2)\vec{n} \cdot (\vec{v}_0 - \vec{v}_1) = 0$, or

$$\vec{n} \cdot (2\vec{v}_0 - \vec{n}) = 0. \tag{21}$$

That is, $\vec{n}$ and $\vec{D} - \vec{n}$ (where $\vec{D} = 2\vec{v}_0$) are always orthogonal. Similar to Eq. (15), Eq. (21) means that $\vec{n}$ defines a chord from the origin to a point on the circumference with a fixed diameter defined by $\vec{D}$. Because $\vec{n}$ is orthogonal to $\vec{u}_1$, this condition defines a unique chord that makes the angle $\phi = (\pi/2) - \theta$ with $\vec{v}_0$. Its direction defines the unit vector $\hat{w}_\theta$, orthogonal to $\vec{u}_\theta$, and therefore

$$\vec{n} = 2v_0 \cos \left( \frac{\pi}{2} - \theta \right) \hat{w}_\theta = 2v_0 \sin(\theta) \hat{w}_\theta. \tag{22}$$

We use Eqs. (22) and (11) for $\vec{u}_1$ and decompose $\vec{v}_0$ into

$$\vec{v}_0 = v_0 (\cos(\theta) \vec{u}_\theta + \sin(\theta) \hat{w}_\theta), \tag{23}$$

so that Eq. (20) becomes

$$\vec{v}_1 = v_0 \left[ \frac{m_1 - m_2}{m_1 + m_2} \cos(\theta) \vec{u}_\theta + \sin(\theta) \hat{w}_\theta \right]. \tag{24}$$

The possible outcomes of $\vec{v}_1$ also have a geometrical locus defined by a circumference centered at

$$\vec{V}_{cm} = \frac{1}{2} \vec{d} = \frac{m_1}{m_1 + m_2} \vec{v}_0 \tag{25}$$

away from the origin, with radius

$$r_v = |\vec{v}_0 - \vec{V}_{cm}| = \frac{m_2}{m_1 + m_2} v_0. \tag{26}$$

This radius is to be expected because $\vec{v}_1 = \vec{v}_0$, $\vec{u}_1 = 0$ is one possible result for the collision, meaning that the closest approach of the two bodies was too far compared to the range of the interaction forces. Confirmation that in general the possible $\vec{v}_1$ define such a circumference results from verifying the orthogonality condition for two particular chords

$$(\vec{v}_1 - \vec{v}_0) \cdot [\vec{v}_1 - \vec{v}_0 + 2(\vec{v}_0 - \vec{V}_{cm})] = 0, \tag{27}$$

which holds when Eqs. (24), (20), and (16) are used, together with the identities $\vec{u}_1 \cdot \vec{d} = \vec{u}_1 \cdot \vec{u}_1$ and $\vec{u}_1 \cdot \vec{n} = 0$:

$$(\vec{v}_1 - \vec{v}_0) \cdot (\vec{u}_1 - \frac{2m_1 \vec{v}_0}{m_1 + m_2} + \vec{n}) = -\frac{m_2}{m_1} \vec{u}_1 \cdot (\vec{u}_1 - \vec{d} + \vec{n}) = 0. \tag{28}$$

**B. Scattering angles in the $u$-body and center of mass frames**

The scattering angles for the collision can now be deduced from the parameters $m_1$, $m_2$, and $\theta$. Relative to the invariant direction $\vec{V}_{cm}$ of the CM, the scattering angle for $\vec{u}_1$ is evidently $\theta$ itself. As for the scattering angle $\varphi$ between $\vec{v}_1$ and $\vec{V}_{cm} || \vec{v}_0$, it can be calculated from Eqs. (24) and (21)

$$\cos(\varphi) = \frac{\vec{v}_1 \cdot \vec{v}_0}{v_1 v_0} = \frac{1 - \frac{2m_2}{m_1 + m_2} \cos^2(\theta)}{\sqrt{1 - \left(\frac{4m_1 m_2}{(m_1 + m_2)^2}\right) \cos^2(\theta)}}. \tag{29}$$

The total scattering angle between $\vec{u}_1$ and $\vec{v}_1$ is $\theta + \varphi$. 

If $m_1 = m_2$, the identity (29) reduces to $\cos(\varphi) = \sin(\theta)$, which means that $\varphi = \phi = (\pi/2) - \theta$ and

$$\vec{u}_1 \cdot \vec{v}_1 = u_1 v_1 \cos(\varphi + \theta) = 0.$$  \hspace{1cm} (30)

Thus, if $m_1 = m_2$, the resulting velocities $\vec{u}_1$ and $\vec{v}_1$ are orthogonal and are both chords of the circumference with diameter $\vec{d} = \vec{v}_0$ (see Fig. 3). This orthogonality is geometrically visible from Eq. (6), which in this equal-mass case reduces to $\vec{v}_1 \cdot \vec{u}_1 = 0$, indicating that the solutions to the collision must remain orthogonal.

Note that if the angle $\varphi$ is specified instead of the angle $\theta$, the determination of $\vec{u}_1$ is geometrically unique when $m_1 < m_2$, but there is an ambiguity when $m_1 > m_2$ because there are two different magnitudes for $\vec{v}_1$ with the same $\varphi$, hence two different angles $\theta$. Direct inversion of Eq. (29) yields

$$\cos^2(\theta) = \frac{1}{2} \left[ 1 + \frac{m_1}{m_2} \sin^2(\varphi) \pm \cos(\varphi) \sqrt{1 - \frac{m_1^2}{m_2^2} \sin^2(\varphi)} \right].$$  \hspace{1cm} (31)

If $m_1 < m_2$ the solution with the $-$ sign is the correct one. This solution can be argued by looking at the limiting case of a missed collision ($\varphi = 0$) with the $m_2$ body at rest. In such a case $\theta$ is ill-defined (because the $m_2$ velocity remains zero), but we can see that in neighboring collision cases, the limit of $\theta$ as $\varphi \to 0$ is $\pm \pi/2$, not zero (see Fig. 4). Actually $\theta = 0$ for a head-on collision, and because $m_1 < m_2$ the outcome for $\vec{v}_1$ corresponds to a back-scattering with $\varphi = \pi$.

If $m_1 > m_2$, real solutions exist only for $\varphi \in [\mp \varphi_L, \varphi_L]$ (indicating that there is no back-scattering in these cases), where

$$\varphi_L = \pm \arcsin\left(\frac{m_2}{m_1}\right).$$  \hspace{1cm} (32)

The two solutions $\theta_{\pm}(\varphi)$ obtained in Eq. (31) now apply. Geometrically this result could be obtained by referring to Fig. 2 and noting that the limiting values $\vec{v}_{1L}, \varphi_L$ for $\vec{v}_1$ and $\varphi$ are obtained when $\vec{v}_1$ is tangent to its locus circumference, that is, perpendicular to $\vec{v}'_1 = \vec{v}_1 - \vec{V}_{cm}$. Because $\vec{v}_{1L} \cdot \vec{v}'_{1L} = 0$.

$$\vec{v}_{1L} \cdot \vec{V}_{cm} = |\vec{v}_{1L}|^2.$$  \hspace{1cm} (33)

Because $|\vec{v}_{1L}|^2 = V_{cm}^2 - v_0^2 = (m_1 - m_2)/(m_1 + m_2)v_0^2$, we have $\cos(\varphi_L) = \sqrt{1 - (m_2/m_1)^2}$, or

$$\sin(\varphi_L) = \pm \frac{m_2}{m_1}. \hspace{1cm} (34)$$

The scattering angle $\varphi$ for the $u$-body can also be related to the scattering angle $\varphi'$ as seen from the CM-frame. We use $\vec{v}_1 = \vec{v}'_1 + \vec{V}_{cm}$ together with Eqs. (29) and (30) and obtain

$$\tan(\varphi) = \frac{v_1' \sin(\varphi')}{V_{cm} + v_1' \cos(\varphi')} = \frac{m_2 \sin(\varphi')}{m_1 + m_2 \cos(\varphi')}.$$  \hspace{1cm} (35)

For equal masses

$$\tan(\varphi) = \tan\left(\frac{\varphi'}{2}\right).$$  \hspace{1cm} (36)

Likewise, the scattering angle $\theta$ for the $u$-body can also be related to $\varphi'$. If we use the fact that $u_1' = V_{cm} and
Equation (41) is equivalent to
\[ \tan(\theta) = \frac{u_i \sin(\varphi)}{V_{cm} - u_i \cos(\varphi)} = \frac{\sin(\varphi)}{1 - \cos(\varphi)}. \] (37)
which simplifies to
\[ \tan(\theta) = \cot\left(\frac{\varphi}{2}\right), \] (38)
which is independent of the mass ratio.

III. ELASTIC COLLISION: GENERAL TWO-DIMENSIONAL CASE

If both bodies are initially moving when viewed from a laboratory frame, the same analysis can be carried out (see Fig. 5). All that is necessary is to switch temporarily to an equivalent inertial frame \( S_{cm} \) moving with the initial \( u \)-body velocity \( \vec{v}_0 \). In this frame the situation is exactly as before, that is, an elastic collision with a body initially at rest. The same equations and conclusions are valid except that everywhere we need to let \( \vec{v}_i \rightarrow \vec{v}_i - \vec{u}_0 \), \( \vec{u}_i \rightarrow \vec{u}_i - \vec{u}_0 \), and \( \vec{V}_{cm} \rightarrow \vec{V}_{cm} - \vec{u}_0 \).

In this case the conservation equations are
\[
\begin{align*}
  m_1 \vec{v}_0 + m_2 \vec{u}_0 &= m_1 \vec{v}_1 + m_2 \vec{u}_1; \quad (39a) \\
  \frac{1}{2} m_1 v_0^2 + \frac{1}{2} m_2 u_0^2 &= \frac{1}{2} m_1 v_1^2 + \frac{1}{2} m_2 u_1^2, \quad (39b)
\end{align*}
\]
which can be rewritten as
\[
\begin{align*}
  m_1 \frac{\vec{v}_0 - \vec{v}_1}{m_2} &= \vec{u}_1 - \vec{u}_0; \quad (40a) \\
  m_1 m_2 \frac{\vec{v}_0 - \vec{v}_1 \cdot (\vec{v}_0 + \vec{v}_1)}{m_2} &= (\vec{u}_1 - \vec{u}_0) \cdot (\vec{u}_1 + \vec{u}_0). \quad (40b)
\end{align*}
\]
Manipulation of Eq. (40) in a manner similar to Sec. III will generate the equivalent relations in this new frame \( S_{cm} \). Equation (41) now becomes
\[ |\vec{u}_1 - \vec{u}_0|^2 = \frac{2m_1}{m_1 + m_2} (\vec{v}_0 - \vec{u}_0) \cdot (\vec{u}_1 - \vec{u}_0). \] (41)
We set as before
\[
\vec{d} = 2(\vec{V}_{cm} - \vec{u}_0) = \frac{2m_1}{m_1 + m_2} (\vec{v}_0 - \vec{u}_0) \quad (42)
\]
\[ \vec{u}_0 = \frac{1}{|\vec{u}_1 - \vec{u}_0|} (\vec{u}_1 - \vec{u}_0), \] (43)
where \( \vec{u}_0 \) is the direction of \( \vec{u}_1 - \vec{u}_0 \) and \( \theta \) is the angle between \( \vec{v}_0 - \vec{u}_0 \) and \( \vec{u}_1 - \vec{u}_0 \). Then
\[ |\vec{u}_1 - \vec{u}_0| = \vec{d} \cdot \vec{u}_0 = \frac{2m_1}{m_1 + m_2} |\vec{v}_0 - \vec{u}_0| \cos(\theta). \] (44)
Note that Eq. (44) is equivalent to
\[ (\vec{u}_1 - \vec{u}_0) \cdot (\vec{u}_1 - \vec{u}_0) = \vec{d} \cdot (\vec{u}_1 - \vec{u}_0), \] (45)
which means that
\[ (\vec{u}_1 - \vec{u}_0) \cdot (\vec{u}_1 - \vec{u}_0 - \vec{d}) = 0. \] (46)
As with Eq. (45), Eq. (46) states that \( \vec{u}_1 - \vec{u}_0 \) always defines a chord from the origin to a circumference of diameter \( \vec{d} \). The final expression for \( \vec{u}_1 \) is thus
\[ \vec{u}_1 = \vec{u}_0 + \frac{2m_1}{m_1 + m_2} (\vec{v}_0 - \vec{u}_0) \cos(\theta) \vec{u}_0. \] (47)
The equivalent of the \( \vec{n} \) vector in Eq. (48) is
\[ \vec{n} = (\vec{v}_0 - \vec{u}_0) + \vec{v}_1 - \vec{u}_1, \] (48)
and its orthogonality to \( \vec{u}_1 - \vec{u}_0 \) remains
\[ (\vec{u}_1 - \vec{u}_0) \cdot \vec{n} = 0. \] (49)
Therefore Eq. (49) becomes
\[ \vec{n} \cdot (2(\vec{v}_0 - \vec{u}_0) - \vec{n}) = 0, \] (50)
and \( \vec{n} \) also defines a chord from the origin to a circumference of diameter \( \vec{D} = 2(\vec{v}_0 - \vec{u}_0) \). Thus geometrically once \( \vec{u}_1 \) is defined then so is \( \vec{n} \) and Eq. (48) yields the final expression for \( \vec{v}_1 \) as
\[ \vec{v}_1 = \vec{n} + \vec{u}_1 - (\vec{v}_0 - \vec{u}_0). \] (51)
In this general case the only invariant direction in the collision is that of the center of mass. It is left as an exercise for the reader to derive a relation between \( \theta, \varphi \), and \( \varphi' \) in the \( u \)-body and CM frames and the scattering deviations from the center of mass direction of the resulting \( \vec{u}_1, \vec{v}_1 \) velocities in the lab frame.

IV. CONCLUSION

We have shown how the relative velocities in a binary elastic collision obey simple geometric relations even for arbitrary masses and initial velocities. As can be seen from Fig. 5, the possible final velocities \( \vec{u}_1 \) and \( \vec{v}_1 \) for given initial conditions lie on two concentric circumferences centered at a point in velocity space defined by \( \vec{V}_{cm} \). The points defined by \( \vec{u}_1, \vec{v}_1, \) and \( \vec{V}_{cm} \) from the origin always define a straight line. These circumferences have radii
\[
\begin{align*}
  r_u &= |\vec{u}_1 - \vec{V}_{cm}| = \frac{m_1}{m_1 + m_2} |\vec{v}_0 - \vec{u}_0| \quad (52a) \\
  r_v &= |\vec{v}_1 - \vec{V}_{cm}| = \frac{m_2}{m_1 + m_2} |\vec{v}_0 - \vec{u}_0|, \quad (52b)
\end{align*}
\]
where \( \vec{v}_1 - \vec{u}_1 \) was replaced by \( \vec{v}_0 - \vec{u}_0 \) because, from Eq. (41) and the orthogonality condition (51) (see Fig. 5),
\[ |\vec{v}_1 - \vec{u}_1|^2 = \vec{n} \cdot (\vec{n} - 2(\vec{v}_0 - \vec{u}_0)) + |\vec{v}_0 - \vec{u}_0|^2 = |\vec{v}_0 - \vec{u}_0|^2. \] (53)
The maximum radius for either of these circumferences is \( r_v = |\vec{v}_0 - \vec{u}_0| \), which occurs when the respective \( i \)-body mass is much smaller than the other, in which case the latter circumference will have a vanishing diameter, meaning that the velocity of the massive body is similar to that of the center of mass itself. If, for instance, \( m_1 \gg m_2 \), then \( \vec{V}_{cm} \approx \vec{v}_0 \approx \vec{v}_1 \). In the limit \( m_2/m_1 \rightarrow 0 \), \( r_v \rightarrow 0 \) and
\[ r_u = \frac{m_1}{m_1 + m_2} |\vec{v}_0 - \vec{u}_0| - |\vec{v}_0 - \vec{u}_0|. \] (54)
All the scattering properties for binary collisions can be obtained from collision diagrams such as those in Figs. 2–5. In particular, the conditions for $v$-body back-scattering or the existence of a maximum scattering angle depends only on the condition $r_v \gtrsim r_u$. An interesting exercise would be to derive the angular $\theta$ range for which an increase in outgoing velocity is obtained for a binary elastic collision with $m_1 < m_2$, $\vec{u}_0 = 0$.

One of us has written a Java application that renders these collision diagrams interactively. The program uses a Live Java library developed by Martin Kraus. Simulations reveal scattering situations that are not intuitively obvious but can be understood when the full two-body motion is explored. In particular, by changing the asymptotic angle $\theta$ and mass ratio $m_2/m_1$, we can obtain the optimum incident condition for a gravity-assisted fly-by (or gravitational slingshot). It is then apparent that the maximum velocity attainable by the smaller mass, $m_1 < m_2$, in a collision is

$$v_{1,\text{max}} = V_{cm} + \frac{m_2}{m_1 + m_2} |\vec{v}_0 - \vec{u}_0| \quad (55)$$

which occurs when both masses exit in the same direction as that of $\vec{V}_{cm}$. As a consequence of Eq. (55), when the massive body is initially at rest (or when the collision is viewed from its rest frame), the maximum velocity attained is $v_{1,\text{max}} = v_0$.

In future work we will show that these collision diagrams are useful for calculating the eccentricities and focal distances for open Keplerian orbits for gravitational scattering or repulsive Coulomb scattering. An explanation of the slingshot maneuver and gravity-assist planetary fly-by can be easily obtained. In this way the orbits can be viewed in the laboratory frame and a study can be made of the optimal incidence angle for a planetary fly-by that delivers the maximum velocity boost in a chosen direction.
