ABSTRACT

Sixteen dairy goats were assigned to a 4 × 4 Latin square design. Full-fat extruded soyabean (EXSB) were fed at rates of 0, 150, 300, and 400 g/day, and grass hay was fed for ad libitum intake. Dietary EXSB had no effect on milk yield and milk fat content (P>0.05). Feeding increasing levels of EXSB linearly increased the concentrations of casein and whey protein in milk, and the concentration of conjugated linoleic acids in milk fat (P<0.05). Feeding EXSB has the potential to improve the quality of milk for processing as well as the nutritive value of milk fat.

KEY WORDS: extruded soyabean, dairy goats, milk protein fractions, conjugated linoleic acids

INTRODUCTION

Full-fat soyabean are of interest as a source of protein and energy in the ration of high yielding dairy ruminants. Various heat treatments have been applied to increase proportions of undegradable protein in the rumen when full-fat soyabean are fed to lactating cows. Attention has also been given to the influence of heat-treated full-fat soyabean on the fatty acid composition of milk fat. In the diets of dairy cows, extruded soyabeans (EXSB), but not ground raw soyabean, elevated the proportions of conjugated linoleic acids (CLA) in milk fat (Chouinard et al., 2001). Conjugated linoleic acids are components of ruminant fat that are of interest since biomedical studies with animal models have demonstrated a number of beneficial health effects. Feeding EXSB would therefore improve the nutritive value of milk fat from a human health point of view. However, similar feeding strategies have not been extensively evaluated with dairy goats. Our objective was

to examine the effects of diets containing increasing levels of EXSB on milk yield, milk composition and milk fatty acid profile in dairy goats.

MATERIAL AND METHODS

Sixteen primiparous dairy goats that averaged 120 days in milk were randomly assigned to a 4×4 Latin square design with 21-day periods. Two squares were composed of Saanen goats, one square was composed of Toggenbourg goats, and one square was composed of Alpine goats. Full-fat EXSB were fed at rates of 0, 150, 300, and 400 g/day as part of grain mixes formulated to be isonitrogenous (Table 1). Chopped grass hay was fed ad libitum.

The first two weeks of each period were used for adjustment to diets and week 3 was used for data collection. During each of these periods, goat weight was recorded for three consecutive days. Hay intake was determined and feed ingredients were sampled for four consecutive days. Milk yield was recorded for six consecutive milkings, and milk was sampled proportionately to milk yield.

| Ingredient, % of DM | Extruded soyabean, g/d |
|---------------------|------------------------|
|                     | 0  | 150 | 300 | 450 |
| Cracked maize       | 70.4 | 66.9 | 63.5 | 60.3 |
| Soyabean meal       | 23.1 | 15.4 | 7.8 | - |
| Extruded soyabean   | -  | 11.2 | 22.3 | 33.3 |
| Molasses            | 1.8 | 1.8  | 1.8  | 1.8 |
| Vitamin and mineral premix | 4.0 | 4.0  | 4.0  | 4.0 |
| Vitamin E (50 000 IU/kg) | 0.7 | 0.7  | 0.7  | 0.7 |

RESULTS

Mean body weight and body weight change were unaffected by treatments. Forage intake expressed as kilograms per day or as a percentage of body weight was not different among treatments. Milk yield and milk corrected for fat and protein content were also unaffected by the level of EXSB supplemented in the diet (Table 2).

The percentage and yield of milk fat did not differ among treatments. Milk crude protein percentage increased linearly with the level of EXSB in the diet. However, milk protein yield was similar among treatments. The percentages of true protein, casein, whey protein, and non casein nitrogen in milk increased linearly with the level of dietary EXSB (Table 3). The concentration of non protein nitrogen was unaffected by treatments. As a result, true protein expressed as a proportion of crude protein increased linearly with the level of EXSB in the diet. Casein expressed as a proportion of true protein was not affected by treatments.
However, the ratio of casein to whey protein decreased linearly with the level of dietary soyabeans.

Feeding increasing amounts of EXSB linearly decreased the proportion of short- and medium-chain fatty acids in milk fat (Table 4). The proportions of C18 fatty acids increased linearly with the level of dietary EXSB.

DISCUSSION

The current experiment shows that feeding EXSB had no major effect on production performances of lactating dairy goats. However, dietary EXSB increased the concentration of casein and whey protein in milk without affecting the proportion of non protein nitrogen. Increasing milk casein content is known to improve cheese yield.

One of the objectives of this study was also to examine the effects of dietary full-fat soyabean on the fatty acid profile of milk fat including CLA concentrations. The CLA content increased by 123% in milk fat of goats fed EXSB at the rate of 450 g/d as compared with unsupplemented diet. Previous investigations (Chouinard et al., 2001) involving dietary addition of processed soyabean in dairy cows have shown increases in milk fat concentration of CLA similar to those observed in the current study with dairy goats.

CONCLUSIONS

Feeding EXSB has the potential to improve the quality of milk for processing as well as the nutritive value of milk fat without affecting production performance in dairy goats.
