Rabi oscillations, decoherence, and disentanglement in a qubit-spin-bath system: exact dynamics

Ning Wu*, Arun Nanduri*, and Herschel Rabitz†
Department of Chemistry, Princeton University, Princeton, NJ 08544

The exact reduced dynamics of a qubit coupled uniformly to a spin bath modeled by the periodic XX spin chain via the XX-type spin flipping qubit-bath interaction is obtained by deriving sets of equations of motion for the time-dependent wavefunctions in the momentum space of the XX chain. We first study the Rabi oscillations of the qubit with the bath prepared in the spin coherent state. It is found that nonresonance and finite intrabath interaction have significant effects on the qubit dynamics. We further discuss the bath-induced decoherence of the qubit with the bath prepared in its ground state. The decoherence properties depend on the internal phases of the spin bath. By considering two independent copies of such qubit-bath subsystems, we also probe the disentanglement dynamics of two initially entangled qubits and find that entanglement sudden death appears in the critical phase of the XX chain. The decoherence factor is found to be an upper bound for the concurrence.

I. INTRODUCTION

The quantum dynamics of a single qubit or central spin coupled to a spin environment [1] has been widely studied theoretically in several different areas, including quantum information sciences [2,3], quantum decoherence [4,5], and excitation energy transfer [6,7]. One of the most promising candidates for quantum computation, solid-state spin systems, are inevitably coupled to their surrounding environment, usually through interactions with neighboring nuclear spins [1,8,9]. The coupling of a qubit to a spin bath can in general lead to non-Markovian behavior [2,10], causing the usual Markovian quantum master equations to fail for such models. Most recently, it was demonstrated for the first time that a spin bath can assist coherent transport in a two-level system [11]. Fully understanding the role played by a spin environment is an interesting and important issue.

One commonly studied qubit-spin bath system is the so-called spin-star network [1,12,13,14,15,16,17,18,19], in which a preferred central spin is coupled homogeneously to a spin bath without intrabath interactions. A more realistic type of environment takes the form of quantum interacting spin chains [1,10,15,16], where the decay of the qubit’s coherence is found to be related to the critical properties of the spin environments. Most prior work making use of such an environment considered qubit-spin bath coupling of the Ising form, which is spin conserving. As a result, it is much easier to analytically obtain the full dynamics of the system, in contrast to the situation where a spin-flip coupling is present. Exceptions include Refs. [20,21], where the authors considered the spin-flip XX-type qubit-bath coupling but with a spin bath having homogeneous self-interactions, and Ref. [22], where the authors use t-DMRG to study the reduced dynamics of a qubit coupled locally to an XXZ spin chain via the Heisenberg-type qubit-bath interaction. It should be noted that, in general, both the spin-star network and the homogeneously coupled spin bath can be treated by introducing collective angular momentum operators which facilitates the analytical treatment. In this work, we will focus on a more realistic system with a uniform spin-flip qubit-bath interaction as well as short range XX-type intrabath interactions. To our knowledge, the exact dynamics of such a model, which is one step closer to faithfully representing environmental spins interacting via fully general Heisenberg-type interactions, has not been obtained before.

The collapse and revival (CR) behavior of Rabi oscillations of a qubit coupled to a single bosonic field mode, described by the Jaynes-Cummings (JC) model, is a fundamental consequence of field quantization and provides a much-studied illustration of the quantum nature of qubit-field systems [16]. Using a correspondence between the JC model and a spin-star network with a large number of spins, it is found in Ref. [22] that within a certain parameter regime, CR phenomena also appear in a qubit-big spin model. Ref. [27] goes beyond the resonant JC model to the nonresonant Dicke model, and notes that the dynamics depends on the sign of the detuning between the qubit and field frequency. In this work, we extend the model studied in Ref. [28] to the nonresonant case with a self-interacting spin bath modeled by the periodic XX spin chain. It is found that both nonzero detuning and the nearest neighbor coupling within the XX bath can have an effect on the qubit’s dynamics. In particular, the interplay between nonresonance and intrabath interaction is able to reproduce CR behavior even for a spin bath with a relatively small number of sites.

In addition, the dynamics of entanglement in many-body systems has recently been studied from different perspectives. As interacting quantum spin systems are believed to be paradigmatic for quantum information processing, their entanglement dynamics has attracted much attention. In prior works, the dynamical behavior of pairwise entanglement is found to be related to quantum phase transitions of the spin chains. Another emerging focus is on the evolution of the entanglement of a pair of qubits exposed to noisy environments. In a seminal work, Yu and Eberly found that the Markovian dynamics of the entanglement between two qubits connected to individual bosonic baths can behave in sharp contrast to single qubit decoherence: the pairwise entanglement of two initially entangled spin-1/2 atoms suddenly disappears in a finite time proportional to the spontaneous lifetime of single qubits, while the single qubit coherence only vanishes asymptotically. This phenomenon is called entanglement sudden death (ESD). More recently, it has been shown in the same setup that the sudden death region and find that ESD always occurs earlier than the onset of decoherence in a single qubit. The initial Bell state considered is the polarized state of the XX bath. The short time dynamics of the decoherence of a single qubit is coupled uniformly with each spin in the spin bath via XX-type interactions. We introduce the collective angular momentum operator $L = \sum_i \sigma_i$, where $\sigma_i = (\sigma_x, \sigma_y, \sigma_z)$. Note that our $H_{SB}$ takes the same form as that in Ref. [28] and [31]. However, there is no intrabath interaction in Ref. [28] and uniform intrabath interactions in Ref. [31]. In this work, we will choose as the spin bath a periodic one-dimensional chain with nearest neighbor interaction $J_{ij} = J \delta_{i+1,j}$, namely, an XX spin chain with periodic boundary conditions. For this system, the total magnetization $M = \sigma_z/2 + L_z$ is a good quantum number. However, the total angular momentum $L^2 = L_x^2 + L_y^2 + L_z^2$ of the spin bath is not conserved due to the finite interaction $J$.

A spin coherent state of the spin bath, which lives in the $l = N/2$ subspace and is parameterized by the unit vector $\hat{\Omega} = (\sin \theta \cos \phi, \sin \theta \sin \phi, \cos \theta)$, can be written as

$$|\hat{\Omega}\rangle = e^{-iL_x \phi} e^{-iL_y \theta} \left( \frac{N}{2} \right)^{-N/2} \sum_{n=0}^{N} C_n D_n^{(N/2)} ,$$

where $C_n = \frac{z^n}{(1+z^2)^{N/2}} \sqrt{C_N^n}$ with $z = \cot \frac{\theta}{2} e^{-i\phi}$, and $|D_n^{(l)}\rangle = |l, n-l\rangle$ ($n \in \{0, 1, ..., 2l\}$) are the fully symmetric Dicke states [39], which are simultaneous eigenstates of $L_x$, $L_y$, and $L_z$. In addition, the dynamics of entanglement in many-body systems has recently been studied from different perspectives. As interacting quantum spin systems are believed to be paradigmatic for quantum information processing, their entanglement dynamics has attracted much attention. In prior works, the dynamical behavior of pairwise entanglement is found to be related to quantum phase transitions of the spin chains. Another emerging focus is on the evolution of the entanglement of a pair of qubits exposed to noisy environments. In a seminal work, Yu and Eberly found that the Markovian dynamics of the entanglement between two qubits connected to individual bosonic baths can behave in sharp contrast to single qubit decoherence: the pairwise entanglement of two initially entangled spin-1/2 atoms suddenly disappears in a finite time proportional to the spontaneous lifetime of single qubits, while the single qubit coherence only vanishes asymptotically. This phenomenon is called entanglement sudden death (ESD). More recently, it has been shown in the same setup that the sudden death region and find that ESD always occurs earlier than the onset of decoherence in a single qubit. The initial Bell state considered is the polarized state of the XX bath. The short time dynamics of the decoherence of a single qubit is coupled uniformly with each spin in the spin bath via XX-type interactions. We introduce the collective angular momentum operator $L = \sum_i \sigma_i$, where $\sigma_i = (\sigma_x, \sigma_y, \sigma_z)$. Note that our $H_{SB}$ takes the same form as that in Ref. [28] and [31]. However, there is no intrabath interaction in Ref. [28] and uniform intrabath interactions in Ref. [31]. In this work, we will choose as the spin bath a periodic one-dimensional chain with nearest neighbor interaction $J_{ij} = J \delta_{i+1,j}$, namely, an XX spin chain with periodic boundary conditions. For this system, the total magnetization $M = \sigma_z/2 + L_z$ is a good quantum number. However, the total angular momentum $L^2 = L_x^2 + L_y^2 + L_z^2$ of the spin bath is not conserved due to the finite interaction $J$.

A spin coherent state of the spin bath, which lives in the $l = N/2$ subspace and is parameterized by the unit vector $\hat{\Omega} = (\sin \theta \cos \phi, \sin \theta \sin \phi, \cos \theta)$, can be written as

$$|\hat{\Omega}\rangle = e^{-iL_x \phi} e^{-iL_y \theta} \left( \frac{N}{2} \right)^{-N/2} \sum_{n=0}^{N} C_n D_n^{(N/2)} ,$$

where $C_n = \frac{z^n}{(1+z^2)^{N/2}} \sqrt{C_N^n}$ with $z = \cot \frac{\theta}{2} e^{-i\phi}$, and $|D_n^{(l)}\rangle = |l, n-l\rangle$ ($n \in \{0, 1, ..., 2l\}$) are the fully symmetric Dicke states [39], which are simultaneous eigenstates of $L_x$, $L_y$, and $L_z$. In this work, we will choose as the spin bath a periodic one-dimensional chain with nearest neighbor interaction $J_{ij} = J \delta_{i+1,j}$, namely, an XX spin chain with periodic boundary conditions. For this system, the total magnetization $M = \sigma_z/2 + L_z$ is a good quantum number. However, the total angular momentum $L^2 = L_x^2 + L_y^2 + L_z^2$ of the spin bath is not conserved due to the finite interaction $J$.
of \( L^2 \) and \( L_z \) with eigenvalues \( l(l+1) \) and \( n - l \). To study the Rabi oscillations of the qubit, the initial state is chosen as the product state

\[
|\psi(0)\rangle = |1\rangle \otimes |\tilde{\Omega}\rangle,
\]

with the qubit in its up state \( |1\rangle \). (The down state will be denoted by \( |\tilde{1}\rangle \).)

It will be convenient to work in the interaction picture with respect to \( H_S + H_B \). The energy levels and eigenstates of \( H_B \) can be obtained by using the Jordan-Wigner transformation \( \sigma^+_i = \prod_{j=1}^{i-1}(1 - 2c_j^tc_j)c_i, \sigma^-_i = 2c_i^tc_i - 1 \), where \( c_i \) are fermionic operators. \( H \) then describes a qubit immersed in a spinless fermion bath,

\[
H = \frac{\omega}{2}(\sigma_z + 1) + \frac{J}{2} \sum_{j=1}^{N} (c_j^tc_{j+1} + c_{j+1}^tc_j) - \hbar \sum_{j=1}^{N} c_j^tc_j + g \sum_{j=1}^{N} (c_j^T T_j \sigma_+ + c_j T_j^T \sigma_+),
\]

where the string operators \( T_j = e^{i\pi \sum_{j=1}^{i-1} c_i^tc_i} \) have the properties

\[
T_j^2 = 1, \ [c_i, T_j] = 0, \ [c_i, T_j] = 0.
\]

One can define two projection operators, \( P_+ = \frac{1+T_{N+1}}{2} \), and \( P_- = \frac{1-T_{N+1}}{2} \), which project onto subspaces where the total fermion number operator \( N_\sigma = \sum_{j=1}^{N} c_j^tc_j \) has even or odd eigenvalues \( N_\sigma \). For even or odd \( N_\sigma \), anti-periodic \( c_{N+1} = -c_1 \) or periodic boundary conditions \( c_{N+1} = c_1 \), respectively, are imposed on the fermions. As a result, we can introduce the following two sets of Fourier transformations,

\[
c_j = \frac{1}{\sqrt{N}} \sum_{k \in K_+} e^{ikj} c_k = \frac{1}{\sqrt{N}} \sum_{k \in K_-} e^{ikj} d_k,
\]

where \( \{c_k\} \) and \( \{d_k\} \) are Fourier modes with wave-numbers surviving in \( K_+ = \{ -\pi, \frac{\pi}{N}, ..., \frac{\pi}{N}, \pi - \frac{\pi}{N}, ..., 0, ..., -\pi + \frac{\pi}{N} \} \) and \( K_- = \{ -\pi, -\pi + \frac{\pi}{N}, ..., \pi - \frac{\pi}{N} \} \), respectively. Now \( H_B \) is diagonalized as

\[
H_B = \sum_{k \in K_+} \varepsilon_k c_k^tc_k + \sum_{k \in K_-} \varepsilon_k d_k^td_k,
\]

with \( \varepsilon_k = J \cos k - \hbar \) the single particle spectrum. By direct calculation, we arrive at the interaction picture Hamiltonian

\[
H_I(t) = e^{i(H_S + H_B)t} H_S B e^{-i(H_S + H_B)t}
= g \sum_{j=1}^{N} \left[ (P_- e^{iH_{-t}} c_j^T T_j e^{-iH_{-t}} P_+ + P_+ e^{iH_{-t}} c_j T_j e^{-iH_{-t}} P_-) \right] \sigma_+ e^{-i\omega t} + \text{H.c.},
\]

where H.c. stands for the Hermitian conjugate. Since \( M \) is a conserved quantity, it is sufficient to study time evolution from the states \( |\psi^{(n)}(0)\rangle = |1\rangle \otimes |D_n^{(\tilde{\Omega})}\rangle \). In the interaction picture, the state evolved from the initial state in Eq. \( 3 \) then reads \( |\psi_I(t)\rangle = \sum_n |c_n\rangle \langle \psi^{(n)}(t)| \), with \( |\psi^{(n)}(t)\rangle = T e^{-i\int_0^t ds H_I(s) d|\psi^{(n)}(0)\rangle} \). In the non-interacting case \( J = 0 \), the total angular momentum of the spin bath is conserved, so \( |\psi^{(n)}(t)\rangle \) will be of the form

\[
|\psi^{(n)}(t)\rangle = a_n(t)|1\rangle|D_n^{(\tilde{\Omega})}\rangle + b_n(t)|\tilde{1}\rangle|\tilde{D}_n^{(\tilde{\Omega})}\rangle.
\]

However, for finite \( J \), \( |\psi^{(n)}(t)\rangle \) will be driven into other \( l \)-subspaces under the action of \( H_I(t) \):

\[
|\psi^{(m)}(t)\rangle = \sum_m a_n^{(m)}(t)|D_n^{(m)}\rangle + \sum_m b_n^{(m)}(t)|\tilde{D}_n^{(m)}\rangle,
\]

which complicates the analysis. To this end, we represent the Dicke states in terms of the fermion operators:

\[
|D_n^{(\tilde{\Omega})}\rangle = \frac{1}{\sqrt{C_{n}^{(\tilde{\Omega})}}} \sum_{j_1 < j_2 < ... < j_n} \sigma_+^{j_1} ... \sigma_+^{j_n} |\tilde{1}\rangle ... |\tilde{1}\rangle
= \frac{1}{\sqrt{C_{n}^{(\tilde{\Omega})}}} \sum_{j_1 < j_2 < ... < j_n} e^{j_1} ... e^{j_n} |0\rangle
= \frac{1}{\sqrt{C_{n}^{(\tilde{\Omega})}}} \sum_{k_1 < k_2 < ... < k_n \ j_1 < j_2 < ... < j_n} S^*(k_1, ..., k_n; j_1, ..., j_n) f_{k_1}^T ... f_{k_n}^T |0\rangle,
\]

where \( f_k = c_k(d_k) \) for even (odd) \( n \). Here \( |0\rangle \) is the vacuum state of the fermions, which corresponds to the state with all bath spins in their down states \( |\tilde{1}\rangle ... |\tilde{1}\rangle \). The function

\[
S(k_1, ..., k_m; j_1, ..., j_m) = \left( \frac{1}{\sqrt{N}} \right)^m \det \begin{pmatrix} e^{ik_1j_1} & e^{ik_1j_2} & ... & e^{ik_1j_m} \\ e^{ik_2j_1} & e^{ik_2j_2} & ... & e^{ik_2j_m} \\ ... & ... & ... & ... \\ e^{ik_mj_1} & e^{ik_mj_2} & ... & e^{ik_mj_m} \end{pmatrix},
\]

is the Slater determinant made up of plane waves. In the following we treat even \( n \) or odd \( n \) separately.

(1) \( n = \text{even} \).

It is easily seen that the most general form of \( |\psi^{(n)}(t)\rangle \) is

\[
|\psi^{(n)}(t)\rangle = |1\rangle \otimes \sum_{k_1 < ... < k_n} B(k_1, ..., k_n; t) \prod_{l=1}^{n} c_{k_l}^0 |0\rangle
+ |\tilde{1}\rangle \otimes \sum_{k_1 < ... < k_{n+1}} D(k_1, ..., k_{n+1}; t) \prod_{l=1}^{n+1} d_{k_l}^0 |0\rangle,
\]

where \( C_{n+1}^{(\tilde{\Omega})} \) is the number of states in the \( n \)-subspace.
where $B(k_1, \ldots, k_n; t)$ and $D(k_1, \ldots, k_n+1; t)$ are coefficients to be determined by the time-dependent Schrödinger equation $i\hbar \partial |\psi^{(n)}(t)\rangle = H_I(t)|\psi^{(n)}(t)\rangle$. After a straightforward calculation (see Appendix A), we arrive at the following two sets of equations of motion for the coefficients $B$ and $D$

\begin{align}
 i\dot{D}(p_1, \ldots, p_{n+1}; t) &= \frac{g}{\hbar} e^{-i\omega t} e^{i\sum_{l=1}^{n+1} \varepsilon_{p_l} t} \sum_{k_1 < \ldots < k_n} \varepsilon_{k_1} B(k_1, \ldots, k_n; t) f^*(p_1, \ldots, p_{n+1}; k_1, \ldots, k_n), \quad (14) \\
 i\dot{B}(p_1, \ldots, p_n; t) &= \frac{g}{\hbar} e^{i\omega t} e^{i\sum_{l=1}^{n} \varepsilon_{p_l} t} \sum_{k_1 < \ldots < k_{n+1}} \varepsilon_{k_1} D(k_1, \ldots, k_{n+1}; t) f(k_1, \ldots, k_{n+1}; p_1, \ldots, p_n), \\
 \quad (15)
\end{align}

where the auxiliary function $f$ is defined to be

\[ f(k_1, \ldots, k_{m+1}; p_1, \ldots, p_m) = \sum_{j_1 < j_2 < \ldots < j_{m+1}} S(k_1, \ldots, k_{m+1}; j_1, \ldots, j_{m+1}) \]

\[ \sum_{l=1}^{m+1} S^*(p_1, \ldots, p_m; j_1, \ldots, j_{m+1}). \]

(16)

Here $(j_1, \ldots, j_{m+1})$ is the string of length $m$, $(j_1, \ldots, j_{l-1}, j_{l+1}, \ldots, j_{m+1})$, where $j_l$ has been removed. Note from Eqs. (14) and (15) that $h$ and $\omega$ only enter the equations of motion through their sum $h + \omega$, the detuning. The initial values of the $B$s and $D$s can be read off from Eq. (11):

\begin{align}
 B(k_1, \ldots, k_n; 0) &= \frac{1}{\sqrt{C_N}} \sum_{j_1 < j_2 < \ldots < j_n} S^*(k_1, \ldots, k_n; j_1, \ldots, j_n), \\
 D(k_1, \ldots, k_n; 0) &= 0. \quad (17)
\end{align}

Note that the above equations also include the case of $n = 0$, where there are no $k$-arguments for $B(\cdot; t)$. The corresponding $f$ function is defined by $f(k_1) = \sum_j S(k_1; j)$.

(2) $n$ odd.

Similarly, the time-evolved states for odd $n$ are of the form

\[ |\psi^{(n)}(t)\rangle = |1\rangle \otimes \sum_{k_1 < \ldots < k_n} B'(k_1, \ldots, k_n; t) \prod_{l=1}^{n} d_{k_l}^* |0\rangle \\
+ |1\rangle \otimes \sum_{k_1 < \ldots < k_{n+1}} D'(k_1, \ldots, k_{n+1}; t) \prod_{l=1}^{n+1} c_{k_l} |0\rangle, \quad (18)\]

where the coefficients $B'$ and $D'$ obey the same sets of equations of motion Eqs. (14-15), except the number of arguments for the $B'$s and $D'$s change.

To get an intuitive understanding of the dynamics, we first consider the non-interacting case $J = 0$. In this case the total angular momentum $L^z$ is conserved. By applying the Schrödinger operator to Eq. (1), we obtain the following equations of motion for the coefficients $a_n(t)$ and $b_n(t)$

\[ i\dot{a_n}(t) = \tilde{g}_n e^{i(h+\omega)t} b_n(t), \]
\[ i\dot{b_n}(t) = \tilde{g}_n e^{-i(h+\omega)^t} a_n(t) \quad (19)\]

with initial conditions $a_n(0) = 1$, $b_n(0) = 0$ and $\tilde{g}_n = g\sqrt{(n+1)(N-n)}$. The solutions are

\[ a_n(t) = e^{\frac{i}{2}(h+\omega)t} \left[ -i(h+\omega) \right] \sin \frac{t}{2} \sqrt{4g_n^2 + (h + \omega)^2} \]
\[ + \cos \frac{t}{2} \sqrt{4g_n^2 + (h + \omega)^2}, \]
\[ b_n(t) = -2i\tilde{g}_ne^{-\frac{i}{2}(h+\omega)t} \sin \frac{t}{2} \sqrt{4g_n^2 + (h + \omega)^2} \]
\[ \quad \quad \quad \quad \frac{\sqrt{4g_n^2 + (h + \omega)^2}}{4g_n^2 + (h + \omega)^2}. \quad (20)\]

The polarization dynamics is given by

\[ \langle \sigma_z(t) \rangle = \sum_{n=0}^{N} |C_n|^2 \left[ |a_n(t)|^2 - |b_n(t)|^2 \right] \]
\[ = 1 - 8 \sum_{n=0}^{N} \tilde{g}_n^2 |C_n|^2 \sin^2 \frac{t}{2} \sqrt{4g_n^2 + (h + \omega)^2}. \quad (21)\]

We note that $\langle \sigma_z(t) \rangle$ is symmetric under changing the sign of the detuning: $h + \omega \rightarrow -(h + \omega)$. The other two components can be calculated directly from Eq. (5):

\[ \langle \sigma_x(t) \rangle = 2\Re \left[ e^{-i\omega t} \sum_{n=1}^{N} C_{n-1}^* C_n b_{n-1}^* a_n \right], \]
\[ \langle \sigma_y(t) \rangle = -2\Im \left[ e^{-i\omega t} \sum_{n=1}^{N} C_{n-1}^* C_n b_{n-1}^* a_n \right]. \quad (22)\]

We also monitor the purity dynamics of the qubit

\[ P_{q\bar{q}}(t) = \frac{1}{2} (1 + \sum_{i=x,y,z} \langle \sigma_i(t) \rangle^2) \]
\[ = \frac{1 + \langle \sigma_x(t) \rangle^2}{2} + 2 \left| \sum_{n=1}^{N} C_{n-1}^* C_n b_{n-1}^* a_n \right|^2. \quad (23)\]

Although $\langle \sigma_x(t) \rangle$ and $\langle \sigma_y(t) \rangle$ depend on both $h + \omega$ and $\omega$, $\langle \sigma_z(t) \rangle$ and $P_{q\bar{q}}(t)$ depend only on $h + \omega$. Fig. 1 shows the dynamics of these four quantities in the resonant case $h + \omega = 0$, where clear CR behavior appears for the polarization dynamics $\langle \sigma_z(t) \rangle$. This observation has been recently made in Ref. [28] via a correspondence between the non-interacting qubit-spin-bath system and the JC model at large $N$. As in the JC model [18], in the collapse regime $gt \approx 2.5$ the polarization only undergoes
very small oscillations with nearly vanishing amplitudes, but is accompanied by a maximum of the purity. We will refer to such CR behavior as ‘conventional’ CR dynamics observed in the resonant case. This behavior can be understood from examining the dynamics of \( \langle \sigma_z(t) \rangle \) and \( \langle \sigma_y(t) \rangle \). For example, \( \langle \sigma_z(t) \rangle \) always vanishes for \( \omega = 0 \) (Fig. 1(a)) while \( \langle \sigma_y(t) \rangle \) reaches its maximum in the collapse regime, indicating the approximate creation of a pure state \( |+\rangle \) with the qubit pointing along the +\( \hat{y} \) direction. We observe that \( \omega \) controls the frequency of rotation of the Bloch vector in the \( x - y \) plane in the conventional collapse region. It was argued in Ref. 23 that the correspondence between the qubit-spin bath model and the JC model only holds for the parameter regime \( |z|^2 \ll 1 \ll N \), and may break down for \( |z|^2 \geq 1 \). In Fig. 1(d), we display the dynamics for \( z = 1.6 \) with all the other parameters the same as in Fig. 1(a). We see that the CR dynamics still survives and that the behavior of \( \langle \sigma_z(t) \rangle \) and purity is almost the same as in Fig. 1(a), but with the qubit evolving into state \( |-\rangle \) in the collapse regime.

Fig. 2 shows the results for the nonresonant and noninteracting case \( (h + \omega)/g \neq 0, J/g = 0 \). From examining different values of the detuning \( h + \omega \), we observe that it controls both the amplitude and period of the oscillations of the envelope of \( \langle \sigma_z(t) \rangle \). Larger values of \( (h + \omega)/g \) lead to longer periods and smaller amplitudes of these oscillations, as can also be seen from Eq. (21). Interestingly, the CR dynamics emerges even for a relatively small number of bath spins \( N = 10 \), which would not occur in the resonant case. However, this is not the conventional CR dynamics as seen in the resonant case.

For \( (h + \omega)/g = 15 \), there is a collapse region for \( \langle \sigma_x \rangle \) and \( \langle \sigma_y \rangle \) at \( gt \approx 30 \), where both the purity and \( \langle \sigma_z(t) \rangle \) suffer from rapid oscillations between 0.5 and 1. More interesting dynamics appears at \( gt \approx 55 \) (Fig. 2(b)), where the purity undergoes small oscillations but remains close in absolute value to unity. We will refer to the behavior in both these regions as ‘unconventional’ CR dynamics. Unlike in the resonant case, where the pure state of the qubit rotates in the \( x - y \) plane, here the qubit moves along the surface of the northern hemisphere of the Bloch sphere.

For finite \( J \), although a closed form solution to the equations of motion cannot be obtained, we have been able to solve Eqs. (14-15) numerically for finite \( N \). To carry out the integration in a reasonable amount of time, it is necessary to solve for the auxiliary f-functions beforehand, and we were able to write a recursive function to do so. This step is the most time consuming, and prevented us from examining systems with larger \( N \). It is also advisable to decouple the system of equations in both Eqs. (14-15) based upon the zeros of the f-functions. Doing so allows each component to be solved in parallel, resulting in a great speedup of the numerical integration.

The three components of the Bloch vector can be calculated from Eq. (13) and Eq. (15):

\[
\langle \sigma_x(t) \rangle = 2\Im[e^{-i\omega t}Z(t)],
\langle \sigma_y(t) \rangle = -2\Re[e^{-i\omega t}Z(t)],
\langle \sigma_z(t) \rangle = 0,
\]

(24)
with

\[ Z(t) = \sum_{n=1}^{N} C_{2n-1}^{*} C_{2n} \]
\[ + \sum_{k_1 < \ldots < k_{2n}} D'(k_1, \ldots, k_{2n}; t) B(k_1, \ldots, k_{2n}; t) + \]
\[ \sum_{n=0}^{N-1} C_{2n}^{*} C_{2n+1} \]
\[ + \sum_{k_1 < \ldots < k_{2n+1}} D'(k_1, \ldots, k_{2n+1}; t) B'(k_1, \ldots, k_{2n+1}; t) \]  

(25)

and

\[ \langle \sigma_z(t) \rangle = \langle \psi_I(t) | \sigma_z | \psi_I(t) \rangle \]
\[ = \sum_{n=0}^{N} |C_{2n}|^2 \sum_{k_1 < \ldots < k_{2n}} |B(k_1, \ldots, k_{2n}; t)|^2 \]
\[ - \sum_{k_1 < \ldots < k_{2n+1}} |D'(k_1, \ldots, k_{2n+1}; t)|^2 \]
\[ + \sum_{n=0}^{N-1} |C_{2n+1}|^2 \sum_{k_1 < \ldots < k_{2n+1}} |B'(k_1, \ldots, k_{2n+1}; t)|^2 \]
\[ - \sum_{k_1 < \ldots < k_{2n+2}} |D'(k_1, \ldots, k_{2n+2}; t)|^2 \]  

(26)

Numerical results for finite intrabath interaction and finite detuning with \( J/g = 0.5 \) and \( (h + \omega)/g = 10 \) are plotted in Fig. 3(a). Comparing with Fig. 2, we see that conventional CR dynamics in \( \langle \sigma_z(t) \rangle \) reappears after introducing finite intrabath coupling. This is shown more clearly in Fig. 3(b). Except for the facts that the oscillation center of \( \langle \sigma_z(t) \rangle \) moves to around 0.5, and that the peaks of the purity are below 1.0 in this case, the dynamics in the collapse region closely mimics that of in Fig. 1(c). This is an intriguing observation, considering that our spin bath contains only a relatively small number of spins (\( N = 10 \)). However, not every peak of the purity is accompanied by the collapse of \( \langle \sigma_z(t) \rangle \), as can be seen from the first and third peaks in Fig. 3(a). In Fig. 3(c), we display the same plot for \( J/g = 1.0 \). We see that increasing the coupling strength \( J/g \) causes the period between successive peaks of the purity to decrease. These revivals in the purity also appear to wash out more quickly than they do in Fig. 3(a).

As mentioned earlier, for \( J = 0 \) the dynamics is symmetric under changing the sign of the detuning \( h + \omega \rightarrow -(h + \omega) \) for fixed \( \omega \). However, this is not the case for finite \( J \), as can be seen from the simple example of \( N = 2 \); i.e., for a spin bath made up of only two spins, where an analytical expression can be obtained:

\[ \langle \sigma_z(t) \rangle = \frac{|C_0|^2}{8g^2} \frac{8g^2 \cos t \sqrt{8g^2 + J_5^2 + J_7^2}}{8g^2 + J_7^2} + \frac{|C_1|^2}{8g^2} \frac{8g^2 \cos t \sqrt{8g^2 + J_5^2 + J_7^2}}{8g^2 + J_7^2} + |C_2|^2 \]

with \( J_5 = h + \omega \pm J \). Note that only the relative sign between \( h + \omega \) and \( J \) is relevant.

### III. ENTANGLEMENT DYNAMICS OF TWO QUBITS COUPLED TO TWO INDIVIDUAL SPIN BATHS

In the previous section, we studied the reduced dynamics of a single qubit coupled to an interacting spin bath, with the bath initially prepared in the spin coherent state. Now we consider two such copies of the qubit-bath system, between which there is no direct interaction:

\[ H = \sum_{q=1,2} \left( H_S^{(q)} + H_B^{(q)} + H_{SB}^{(q)} \right), \]

(27)
with \( H^{(q)}_B \), \( H^{(q)}_S \), and \( H^{(q)}_{SB} \) given by Eq. \( (1) \), and the upper index indicating the operators for copies \( q = 1 \) or \( 2 \).

As shown in Ref. [31], the reduced dynamics of the two qubits can be determined completely from that of only one of the two copies. Explicitly, let \( \rho(t) \) denote the reduced density matrix of the two qubits. Assuming a separable initial state \( \rho_{tot}(0) = \rho(0) \otimes \rho_B \), \( \rho(t) \) can be written in the basis of the two qubits \( \{ |11\rangle, |\bar{1}\bar{1}\rangle, |\bar{1}1\rangle, |1\bar{1}\rangle \} \) as

\[
\rho_{aa',bb'}(t) = \sum_{c,c',d,d'} W^{(1)}_{abcd}(t) W^{(2)}_{a'b'c'd'}(t) \rho_{c,c',d,d'}(0),
\]

where \( W^{(q)}_{abcd}(t) \) is determined by the dynamics of each part through

\[
\rho^{(q)}_{ab}(t) = \sum_{cd} W^{(q)}_{abcd}(t) \rho^{(q)}_{cd}(0), \quad q = 1, 2
\]

for an initial state \( \rho^{(q)}(0) \otimes \rho^{(q)}_B \) of copy \( q \).

Thus, in the following we focus on the dynamics of a single qubit coupled to a single bath described by Eq. \( (1) \), and drop the upper index \( q \) for simplicity. Obviously, the dynamics depends on the initial state of the bath \( \rho_B \). In this section, we will choose the ground state of the isolated XX chain as the bath’s initial state.

Prior to carrying out the analysis, we recall some general results on the ground state structure of the XX chain with periodic boundary conditions. We set \( J = -1 \) and \( h \geq 0 \) henceforth. For a chain with a finite number of sites, lowering \( h \) from the critical field \( h_c = 1 \) to \( h = 0 \) causes \( N/2 \) level crossings, which correspond to transitions between different parity sectors. This leads to the Kosterlitz-Thouless phase transition in the thermodynamic limit.

The level crossing or parity changing occurs at the following \( N/2 \) critical fields:

\[
h_m = -\frac{\cos(m - \frac{1}{2}) \pi}{\cos \frac{\pi}{2} \frac{N}{2}}, \quad m = \frac{N}{2} - \frac{N}{2} + 1, \ldots, N - 1.
\]

Note that \( h_{N-1} = h_c = 1 \), so that the region \( h \in [0, +\infty) \) is divided into the following intervals:

\[
i) : h_m \leq h \leq h_{m+1}, \quad m = \frac{N}{2} - \frac{N}{2} + 1, \ldots, N - 2.
\]
\[
ii) : 1 \leq h,
\]
\[
iii) : 0 \leq h \leq h_{\frac{N}{2}}.
\]

For fields within interval \( i) \) and with \( m \) even, the ground state is filled by \( m + 1 \) \( d \)-fermions

\[
|g_m\rangle_d = d^\dagger_{-m} d^\dagger_{-(m-2)} \ldots d^\dagger_0 d^\dagger_{(m-2)} \vdots d^\dagger_m |0\rangle,
\]

and possesses an energy

\[
E^{(d)}_m = -(h + 1) - 2 \sum_{l=1}^{m} \left( \cos \frac{2\pi l}{N} + h \right).
\]

Similarly, for odd \( m \), the ground state is filled by \( m + 1 \) \( c \)-fermions

\[
|g_m\rangle_c = c^\dagger_{-m} c^\dagger_{-(m-2)} \ldots c^\dagger_0 c^\dagger_{m} |0\rangle,
\]

with energy

\[
E^{(c)}_m = -2 \sum_{l=1}^{m+1} \left( \cos \frac{(2l-1)\pi}{N} + h \right).
\]

For fields within interval \( ii) \), the ground state is always the fully polarized state with all spins pointing in the \( +\hat{z} \) direction. In the fermionic picture, this state corresponds to the completely occupied state \( |g_{N-1}\rangle_c \) which is filled by the \( c \)-fermions and has an energy \(-hN\). Depending on whether \( N = 4n \) or \( N = 4n + 2 \), the ground state for fields within interval \( iii) \) will be either \( |g_{N/2-1}\rangle_c \) or \( |g_{N/2+1}\rangle_d \).

In order to get a better understanding of the relationship between decoherence and disentanglement, which is believed to be of importance for both the foundation of quantum mechanics and practical applications of quantum information [24], we first study the decoherence dynamics of a single qubit.

### A. Single qubit decoherence

We suppose that initially the qubit is not entangled with the XX bath. That is,

\[
|\phi(0)\rangle = (a_1 |\bar{1}\rangle + a_1 |1\rangle) \otimes |g_{XX}\rangle,
\]

where \( |g_{XX}\rangle \) is the ground state of the XX chain. The coefficients \( a_1 \) and \( a_1 \) satisfy \( |a_1|^2 + |a_1|^2 = 1 \). Note that \( |g_{XX}\rangle \) is not an eigenstate of Eq. \( (1) \), so the evolution starting from \( |\phi(0)\rangle \) is non-trivial. The spin-flip qubit-bath coupling will induce entanglement between the qubit and spins in the XX chain. We have seen that \( |g_{XX}\rangle \) can be characterized by the number of excitations \( N_e \) within the XX chain. In the real space spin representation described by Eq. \( (1) \), such a state is a linear combination of spin configurations with \( N_e \) up spins. The state will evolve into superpositions of states within subspaces with \( N_e \pm 1 \) excitations due to the interaction term \( H_{SB} \).

Let us first focus on the case of \( 0 < h < 1 \), where the excitation number \( N_e = m + 1 \leq N - 1 \). Depending on the parity of the filling number \( m \), we will use indices ‘\( o \)’ or ‘\( e \)’ to indicate quantities corresponding to odd or even \( m \). For \( |g_{XX}\rangle = |g_m\rangle_c \) with \( m \) odd, the most general
form of $|\phi_I(t)\rangle$ will be

$$
|\phi_I(t)\rangle_o = \sum_{k_1 \ldots k_{m+1}} [a_1 A(k_1, \ldots, k_{m+1}; t)|1\rangle
+a_1 B(k_1, \ldots, k_{m+1}; t)|1\rangle \prod_{l=1}^{m+1} c_{k_l}^\dagger |0\rangle
+ \sum_{k_1 \ldots k_{m+1}} a_1 D(k_1, \ldots, k_{m+1}; t)|1\rangle \prod_{l=1}^{m+2} d_{k_l}^\dagger |0\rangle
+ \sum_{k_1 \ldots k_{m+1}} a_1 C(k_1, \ldots, k_{m+1}; t)|1\rangle \prod_{l=1}^{m} c_{k_l}^\dagger |0\rangle.
$$

(37)

By similar calculations as in the spin coherent state case, we find that $B$ and $D$ obey the same set equations of motion as Eqs. (24) and (25). In addition, the equations of motion for $A$ and $C$ read

$$
i \dot{C}(p_1, \ldots, p_m; t) = ge^{i\omega t} e^{i\sum_{l=1}^{m+1} \epsilon_{p_l} t} \sum_{k_1 \ldots k_m} e^{-i\sum_{l=1}^{m+1} \epsilon_{k_l} t} A(k_1, \ldots, k_{m+1}; t)f(k_1, \ldots, k_{m+1}; p_1, \ldots, p_m),
$$

(38)

$$
i \dot{A}(p_1, \ldots, p_{m+1}; t) = ge^{-i\omega t} e^{i\sum_{l=1}^{m+1} \epsilon_{p_l} t} \sum_{k_1 \ldots k_m} e^{-i\sum_{l=1}^{m+1} \epsilon_{k_l} t} C(k_1, \ldots, k_{m+1}; t)f^*(p_1, \ldots, p_{m+1}; k_1, \ldots, k_{m}).
$$

(39)

All the nonzero initial values of these variables can be read from Eq. (24) and Eq. (25)

$$A(-m \frac{\pi}{N}, \ldots, m \frac{\pi}{N}; 0) = B(-m \frac{\pi}{N}, \ldots, m \frac{\pi}{N}; 0) = 1.
$$

(40)

All other initial values of $A$, $B$, $C$ and $D$ vanish.

Similarly, for $|g_{XX}\rangle = |g_m\rangle_d$ with $m$ even, $|\phi_I(t)\rangle$ will be of the form

$$
|\phi_I(t)\rangle_e = \sum_{k_1 \ldots k_{m+1}} [a_1 A'(k_1, \ldots, k_{m+1}; t)|1\rangle
+a_1 B'(k_1, \ldots, k_{m+1}; t)|1\rangle \prod_{l=1}^{m+1} d_{k_l}^\dagger |0\rangle
+ \sum_{k_1 \ldots k_{m+1}} a_1 D'(k_1, \ldots, k_{m+1}; t)|1\rangle \prod_{l=1}^{m+2} d_{k_l}^\dagger |0\rangle
+ \sum_{k_1 \ldots k_{m+1}} a_1 C'(k_1, \ldots, k_{m+1}; t)|1\rangle \prod_{l=1}^{m} d_{k_l}^\dagger |0\rangle.
$$

(41)

We are now ready to trace out the bath degrees of freedom to obtain the reduced density matrix of the qubit, and hence the $W$ factors in Eq. (29). Note that $[P_y H_y P_y, P_- H_- P_-] = 0$, so the trace can be taken over $c$-fermions and $d$-fermions independently: $\rho_o(t) = tr_c(d)(|\phi_S(t)\rangle_o \langle \phi_S(t)|)$ with the Schrödinger picture state given by $|\phi_S(t)\rangle_o = e^{-i(H_S + H_B)t}|\phi_I(t)\rangle_o$. By using Eq. (29), we obtain the $W$ factors

$$
W_{11}^{(o)}(t) = \sum_{k_1 \ldots k_{m+1}} |B(k_1, \ldots, k_{m+1}; t)|^2,
$$

$$
W_{1111}^{(o)}(t) = \sum_{k_1 \ldots k_{m}} |C(k_1, \ldots, k_{m}; t)|^2,
$$

$$
W_{111}^{(o)}(t) = \sum_{k_1 \ldots k_{m}} |D(k_1, \ldots, k_{m+2}; t)|^2,
$$

$$
W_{1111}^{(o)}(t) = \sum_{k_1 \ldots k_{m+1}} |A(k_1, \ldots, k_{m+1}; t)|^2,
$$

$$
W_{111}^{(o)}(t) = W_{1111}^{(o)}(t),
$$

(42)

with all other elements vanishing. Similar expressions hold for even $m$, with $A$, $B$, $C$ and $D$ replaced by $A'$, $B'$, $C'$ and $D'$. We recognize the decoherence factor of a single qubit $\rho(r)$ from Eq. (29) as

$$r(t) = W_{1111}^{(o)}(t),
$$

(43)

whose absolute value is bounded by $0 \leq |r(t)|^2 \leq 1$, corresponding to complete decoherence and no loss of coherence, respectively.

In Fig. 1, we plot the temporal evolution of the decoherence factor $|r(t)|^2$ for different values of nearest neighbor couplings $J/g$ in the weak qubit-bath coupling regime $|J/g|, h \gg 1$. The revival of coherence occurs since the bath is finite. The loss of coherence is modest for the smallest value of $|J/h| = 0.5$. $|r(t)|^2$ approaches zero only for values $J/h < -1$, namely, in the critical regime of the XX chain. As the intrabath interaction strength $|J/h|$ is increased, the coherence of the qubit is first suppressed, as can be seen by comparing the curves for $J/h = -1.05$ and $J/h = -0.5$, and then enhanced, as can be seen by examining the curves for $J/h = -1.5$ and $J/h = -6.0$. These observations indicate that the relationship between decoherence and interaction strength is not straightforward.

Fig. 1(a) displays the short time behavior of the decoherence factor $|r(t)|^2$. It can be seen that when $gt$ is small, $|r(t)|^2$ decays as a Gaussian

$$|r(t)|^2 \sim e^{-\alpha(gt)^2}.
$$

(44)

In Fig. 1(b), we display several values of the exponent $\alpha$ for different values of $|J/h|$ as blue dots which were
we numerically fit to $|r(t)|^2$ for small times. Interestingly, we note that $\alpha$ exhibits plateaus as a function of $|J/h|$. This behavior can be understood from second-order time-dependent perturbation theory in the qubit-bath coupling $g/J$. It turns out that the initial Gaussian rate is given by (see Appendix B)

$$\alpha = \sum_{p_1 < \ldots < p_m} |f(k_1, \ldots, k_{m+1}; p_1, \ldots, p_m)|^2$$

$$+ \sum_{p_1 < \ldots < p_{m+2}} |f(p_1, \ldots, p_{m+2}; k_1, \ldots, k_{m+1})|^2,$$

where $(k_1, \ldots, k_{m+1}) = (-m \frac{\pi}{2}, \ldots, m \frac{\pi}{2})$ or $(-m \frac{\pi}{2}, \ldots, 0, \ldots, m \frac{\pi}{2})$ for initial states with $|g \chi\rangle = |g_m\rangle_c$ or $|g_m\rangle_d$. This perturbative result is displayed as the red set of plateaus in Fig. 4(b). Note that the $f$-functions, and hence the rate $\alpha$, have nothing to do with the system’s parameters and only depend on the filling number $m$, which explains the presence of plateaus. In Fig. 4(a), two curves are plotted for each value of $m$, and for $g t < 0.03$ the ten curves are seen to collapse into five groups corresponding to the five different values of $m$. The first divergence within a group can be seen for the $m = 5$ sector, where the curves for $J/h = -4.0$ and $J/h = -6.0$ separate past $g t \approx 0.03$.

The short time behavior of the decoherence factor for intermediate qubit-bath coupling, with $h/g = 1$, and strong qubit-bath coupling, with $h/g = 0.1$ (not shown here), is similar to that of weak qubit-bath coupling. In particular, they are also characterized by Gaussian behavior. However, the behavior at longer times, as $|J/h|$ is increased, changes. In order to quantitatively compare the behavior of $|r(t)|^2$ in these three regimes, in Fig. 5(a) we plot the value of the first maximum of the decoherence factor $|r|_{\text{max}}^2$ (aside from the initial value $|r(0)|^2 = 1$) as a function of the intrabath interaction strength $|J/h|$ for the three coupling regimes examined above. This quantity is representative of the extent to which coherence is maintained in the qubit. For all three regimes, when the bath is in a polarized phase $|J/h| < 1$, the decoherence factor returns to unity after one oscillation, and indeed it appears that the periodic revival of the coherence continues for all times. All of the curves exhibit a sudden drop at $|J/h| = 1$, reflecting the transition to the critical phase of the bath. Interestingly, in the critical region $|J/h| > 1$, $|r|_{\text{max}}^2$ displays markedly different behavior in each regime. For weak qubit-bath coupling, $|r|_{\text{max}}^2$ behaves non-monotonically and oscillates about
high values. However, \(|r|_{\text{max}}^2\) appears to monotonically increase for \(h/g = 1\) and \(h/g = 0.1\), albeit very slowly for the latter. These results seem to show that strong intrabath interaction strength suppresses the decoherence of the qubit, a result has been observed for a qubit coupled to a spin bath with homogeneous self-interaction \([22, 35]\).

As another means of assessing the effect of intrabath interactions on the coherence of the qubit, in Fig. 6 we plot the time \(gt\) at which the decoherence factor \(|r(t)|^2\) reaches its first minimum as a function of \(|J/h|\) for the three qubit-bath coupling regimes. We focus on the critical region \(|J/h| > 1\), as the time of the first minimum for \(|J/h| \leq 1\) is much larger and does not display much variation. Interestingly, the green curve, for which \(h/g = 10\), initially decreases sharply with each successive sector and then displays a global minimum at \(|J/h| \approx 3.8\), where the decoherence disappears the quickest. For intermediate and strong qubit-bath coupling \(h/g = 1\) and \(h/g = 0.1\), as \(|J/h|\) is increased and successive magnetization sectors of the bath are encountered, the time \(gt\) of the first minimum drops. But unlike the weak coupling case, \(gt\) increases monotonically within each sector, agreeing with previous results that strong interactions within the bath suppress decoherence of the qubit \([22]\).

**B. Disentanglement of two initially entangled qubits**

Now, we turn to the study of the disentanglement of two qubits interacting with independent XX-baths. We focus on one type of initial state for the two-qubit system \(|\Psi⟩ = α|11⟩ + β|1\bar{1}⟩\) with \(α\) real and \(α^2 + |β|^2 = 1\). From Eq. (46), it follows that the time evolved reduced density matrix for the two qubits reads

\[
ρ(t) = \begin{pmatrix}
ρ_{11,11}(t) & 0 & 0 & 0 \\
0 & ρ_{11,ii}(t) & ρ_{i1,11}(t) & 0 \\
0 & ρ_{1i,11}(t) & ρ_{11,ii}(t) & 0 \\
0 & 0 & 0 & ρ_{ii,ii}(t)
\end{pmatrix},
\]

with

\[
ρ_{11,11}(t) = W_{1111}(t)W_{1111}(t),
ρ_{11,ii}(t) = α^2W_{1111}(t)W_{1111}(t) + |β|^2W_{1111}(t)W_{1111}(t),
ρ_{1i,ii}(t) = αβW_{1i11}(t)W_{1i11}(t),
ρ_{ii,11}(t) = αβW_{i111}(t)W_{i111}(t) + |β|^2W_{ii11}(t)W_{ii11}(t),
ρ_{ii,ii}(t) = W_{ii11}(t)W_{ii11}(t),
\]

where we have assumed that the two environments are identical, so that \(W_{abcd}(t) = W_{abcd}(t) = W_{abcd}(t)\). We use Wootter’s concurrence \([33]\) to measure the bipartite entanglement between the two qubits. The concurrence is defined as

\[
C(t) = \max\{0, 2λ_{\text{max}}(t) - tr\sqrt{ρ(t)\bar{ρ}(t)}\},
\]

\[
\hat{ρ}(t) = σ_y ⊗ σ_y ρ^*(t)σ_y ⊗ σ_y,
\]

where \(λ_{\text{max}}\) is the largest eigenvalue of the matrix \(\sqrt{ρ(t)\bar{ρ}(t)}\). The concurrence for state \(ρ(t)\) reads

\[
C(t) = \max\{0, 2|αβ||r(t)|^2 - 2\sqrt{ρ_{11,11}(t)ρ_{11,11}(t)}\},
\]

where \(|r(t)|^2\) is the single qubit decoherence factor in Eq. (43).

In Fig. 7, we plot the evolution of concurrence as a function of \(gt\) from the maximally entangled Bell state.
The disentanglement dynamics and the decoherence of a single qubit, we set all parameters to be the same as those in Fig. 5. The concurrence appears to be bounded from above by the corresponding decoherence factor $|r(t)|^2$ for all time. For $0 > J/h > -1$, the XX chain is in the fully polarized state along the $+\hat{z}$ direction. The concurrence shows regular oscillations about a high value and never vanishes in this regime. In fact, we have seen that the two-qubit concurrence $C(t)$ exactly coincides with the single qubit decoherence factor $|r(t)|^2$ here. This relation can be understood by examining Eq. (50): for $2|\alpha\beta||r(t)|^2 - 2\sqrt{\rho_{11,11}(t)\rho_{11,11}(t)} \leq 0$, we have $C(t) = 0 \leq |r(t)|^2$; while for $2|\alpha\beta||r(t)|^2 - 2\sqrt{\rho_{11,11}(t)\rho_{11,11}(t)} > 0$, we have

$$C(t) = 2|\alpha\beta||r(t)|^2 - 2\sqrt{\rho_{11,11}(t)\rho_{11,11}(t)}$$

$$\leq 2|\alpha\beta||r(t)|^2 \leq |r(t)|^2.$$  

Hence, the concurrence is always bounded from above by $|r(t)|^2$. When the spin bath is in a polarized state, we always have $D\{k_i\}; t = 0$, as can be seen from Eq. (33). Therefore, $C(t) = 2|\alpha\beta||r(t)|^2 = |r(t)|^2$ for the Bell state with $\alpha = \beta = 1/\sqrt{2}$. A similar conclusion also holds for the other type of entangled state $\alpha|\bar{1}\bar{1} + \beta|11\rangle$. This relationship between decoherence and disentanglement has also been observed before in other system-bath models [55, 56].

On the other hand, ESD always exists in the critical regime $J/h < -1$. This is consistent with the result for two distant qubits coupled locally to an XXZ spin chain via isotropic Heisenberg qubit-bath coupling [53], where it was found that ESD is absent in the ferromagnetic or polarized phase of the spin bath. We also observe that ESD always occurs earlier than the minimum of the corresponding single-qubit decoherence factor, a result in agreement with the case of qubits coupled to independent bosonic baths [51]. In the sudden death region, revival of the entanglement appears a period of time after disentanglement, which is also observed in Ref. [51]. This revival phenomenon is induced by the non-Markovian nature of the spin bath [11].

In order to compare the entanglement dynamics with the decoherence of a single qubit, we plot the disentanglement time, which is defined as the time when the concurrence first vanishes, as a function of intrabath coupling $|J/h|$ in the sudden death region $|J/h| > 1$ in Fig. 8. The time $gt$ until ESD occurs decreases as sectors with lower filling factors $m$ are encountered, but within each sector, $gt$ increases as $|J/h|$ is increased, although this effect is only pronounced for weak qubit-bath coupling $h/g = 10$. This plot displays many similarities to Fig. 4. However, for the green curve with $h/g = 10$, increasing $|J/h|$ only causes an increase in $gt$ with each sector, in contrast to the nonmonotonic behavior of the corresponding curve in Fig. 4. Also, the intrabath coupling strengths at which the entanglement dies the fastest and at which the decoherence is minimized most quickly are not the same. In spite of these differences, there is a qualitative agreement between Figs. 4 and 8 indicating that the decoherence dynamics of a single qubit and the entanglement dynamics of two noninteracting qubits are linked, especially when the qubits are strongly coupled to their respective baths.
IV. CONCLUSIONS

In this work, we studied the reduced dynamics of a specific qubit-spin-bath model. Unlike the spin conserving Ising-type qubit-bath coupling utilized in most previous works, we considered an XX-type spin flipping qubit-bath coupling, which complicates the analytical analysis, since the system-bath interaction term does not commute with the rest of the Hamiltonian. In addition, we model interactions in the bath by introducing nearest-neighbor XX-type couplings among the bath spins. Such a model may be more physical than the non-interacting ‘spin star’ and homogeneously interacting spin baths which have been examined before, but is more difficult to treat analytically. However, by mapping this XX chain into momentum space via the Jordan-Wigner transformation, we have shown how to obtain the equations of motion for the time-dependent total wavefunctions in momentum space. The reduced dynamics of a single qubit is then obtained by tracing out the bath degrees of freedom.

Using the above results, we first studied the Rabi oscillations of the qubit with the bath initially prepared in a spin coherent state. Interestingly, the interplay between off-resonance and intrabath interactions was found to produce conventional collapse and revival behavior even for a relatively small spin bath size. We further discussed the bath-induced decoherence of a single qubit with the bath’s initial state taken to be its ground state. We found that the decoherence properties of the qubit depend on the internal phases of the XX bath. Specifically, the short time decay rate of the decoherence factor only depends on the filling number of the bath ground state. This result was confirmed through second order time-dependent perturbation theory. Finally, we considered two independent copies of such qubit-bath subsystems and studied the disentanglement dynamics of two initially entangled qubits. The two qubits are always entangled if the XX bath is in its polarized state, whereas entanglement sudden death appears in the critical phase. Qualitative similarities were observed between the time dependence of the two-qubit entanglement and the single-qubit decoherence factor, and we showed that the concurrence is bounded from above by the decoherence factor of the single qubit.

The central spin model can be used broadly to understand the influence of the environment on systems ranging from electron spins of atomic impurities embedded in solid-state devices to nuclear spins in semiconductor quantum dots. The ability to control the strength of both intrabath and the qubit-bath couplings of such systems has been demonstrated, for example, in NV centers in diamond. As our results suggest that turning on interactions among bath spins can have markedly different effects on the decoherence and entanglement properties of the central spins depending on how strongly they are coupled to their environment, this work may be of relevance to all efforts aimed at using such systems to construct quantum information processing devices.

\[ i \partial_t |\psi^{(n)}\rangle = H_1(t) |\psi^{(n)}\rangle \quad (51) \]

After acting with \( H_1(t) \) on \( |\psi^{(n)}(t)\rangle \), only two terms survive:

\[ H_1(t) |\psi^{(n)}(t)\rangle = |\psi_{\text{e}}^{(n)}(t)\rangle + |\psi_{\text{d}}^{(n)}(t)\rangle, \]

\[ |\psi_{\text{e}}^{(n)}(t)\rangle = g \sum_{j=1}^{N} P_+ e^{i H_1 \cdot T_j} e^{-i \omega t} |P_+ \sigma_- e^{-i \omega t}| 1 \]
\[ \sum_{k_1 < \ldots < k_n} B(k_1, \ldots, k_n; t) \prod_{l=1}^{n} d_{k_l}^+ |0\rangle, \]

\[ |\psi_{\text{d}}^{(n)}(t)\rangle = g \sum_{j=1}^{N} P_- e^{i H_1 \cdot T_j} e^{-i \omega t} |P_- \sigma_- e^{i \omega t}| 1 \]
\[ \sum_{k_1 < \ldots < k_{n+1}} D(k_1, \ldots, k_{n+1}; t) \prod_{l=1}^{n+1} d_{k_l}^+ |0\rangle. \quad (52) \]

\( |\psi_{\text{e}}^{(n)}(t)\rangle \) can be calculated as

\[ |\psi_{\text{e}}^{(n)}(t)\rangle = g e^{-i \omega t} |1\rangle e^{i H_1 \cdot T} \sum_{k_1 < \ldots < k_n} e^{-i \sum_{l=1}^{n} \epsilon_{k_l} t} B(k_1, \ldots, k_n; t) |\chi_{k_1, \ldots, k_n}\rangle, \quad (53) \]
with

$$|\chi_{k_1,...,k_n} \rangle = \sum_{j=1}^{N} c_j^T T_j \prod_{l=1}^{n} c_{k_l}^T |0\rangle$$

$$= \sum_{j=1}^{N} T_j c_j^T \sum_{j_1<j_2<...<j_n} S(k_1,...,k_n; j_1,...,j_n) c_j^T c_{j_1}^T c_{j_2}^T \cdots c_{j_n}^T |0\rangle + ...$$

$$+ \sum_{j_1<...<j_l<j_{l+1}<...<j_n} S(k_1,...,k_n; j_1,...,j_{l-1},j_{l+1},...,j_n) c_j^T c_{j_1}^T c_{j_2}^T \cdots c_{j_l}^T \cdots c_{j_{l+1}}^T c_{j_{l+2}}^T \cdots c_{j_n}^T |0\rangle + ...$$

$$= \sum_{j_1<...<j_l<j_{l+1}<...<j_n} \left( \sum_{l=1}^{n} S(k_1,...,k_n; j_1,...,j_l) \right) \sum_{p_1<...<p_{n+1}} S^*(p_1,...,p_{n+1}; j_1,...,j_n) d_{p_1}^T d_{p_{n+1}}^T |0\rangle.$$  (54)

Here \((j_1,...,j_l,...,j_{m+1})\) is the string of length \(m\), \((j_1,...,j_{l-1},j_{l+1},...,j_{m+1})\), where \(j_l\) has been removed. So, \(|\psi_c^{(n)}(t)\rangle\) is given by

$$|\psi_c^{(n)}(t)\rangle = \sum_{k_1<...<k_n} e^{-i \sum_{l=1}^{n} \epsilon_{k_l} t} B(k_1,...,k_n; t) \sum_{j_1<...<j_l<...<j_n} \left( \sum_{l=1}^{n} S(k_1,...,k_n; j_1,...,j_l) \right) \sum_{p_1<...<p_{n+1}} S^*(p_1,...,p_{n+1}; j_1,...,j_n) d_{p_1}^T d_{p_{n+1}}^T |0\rangle.$$  (55)

Comparing with the left hand side of Eq. (34), we obtain

$$i \dot{D}(p_1,...,p_{n+1}; t) = \sum_{k_1<...<k_n} e^{-i \sum_{l=1}^{n} \epsilon_{k_l} t} B(k_1,...,k_n; t) \sum_{j_1<...<j_l<...<j_n} \left( \sum_{l=1}^{n} S(k_1,...,k_n; j_1,...,j_l) \right) \sum_{p_1<...<p_{n+1}} S^*(p_1,...,p_{n+1}; j_1,...,j_n) e^{i \sum_{l=1}^{n+1} \epsilon_{p_l} t}.$$  (56)

By introducing the auxiliary function in Eq. (4), we obtain Eq. (4). The equations of motion for the \(B\)s can be derived similarly.
Comparing with Eq. (37) in the main text, we have

\[
A(k_1, \ldots, k_{m+1}; t) = 1 + g^2 \sum_{p_1 < \ldots < p_m} \sum_{l=1}^{m+1} \varepsilon_{p_l} - \sum_{l=1}^{m+1} \varepsilon_{k_l}
\frac{e^{-i(\omega + \sum_{l=1}^{m+1} \varepsilon_{p_l} - \sum_{l=1}^{m+1} \varepsilon_{k_l})t} - 1}{(\omega + \sum_{l=1}^{m} \varepsilon_{p_l} - \sum_{l=1}^{m+1} \varepsilon_{k_l})^2} \left| f(k_1, \ldots, k_{m+1}; p_1, \ldots, p_m) \right|^2,
\]

\[
B(k_1, \ldots, k_{m+1}; t) = 1 + g^2 \sum_{p_1 < \ldots < p_{m+2}} \sum_{l=1}^{m+1} \varepsilon_{p_l} - \sum_{l=1}^{m+2} \varepsilon_{k_l}
\frac{e^{i(\omega + \sum_{l=1}^{m+2} \varepsilon_{p_l} - \sum_{l=1}^{m+2} \varepsilon_{k_l})t} - 1}{(\omega + \sum_{l=1}^{m+1} \varepsilon_{p_l} - \sum_{l=1}^{m+2} \varepsilon_{k_l})^2} \left| f(p_1, \ldots, p_{m+2}; k_1, \ldots, k_{m+1}) \right|^2,
\]

(60)

and

\[
A(p'_1, \ldots, p'_{m+1}; t) = O(g^2),
\]

\[
B(p'_1, \ldots, p'_{m+1}; t) = O(g^2),
\]

(61)

for \((p'_1, \ldots, p'_{m+1}) \neq (k_1, \ldots, k_{m+1})\). From Eq. (42), we finally obtain

\[
|r(t)|^2 = 1 + 2g^2 \sum_{p_1 < \ldots < p_m} \left| f(k_1, \ldots, k_{m+1}; p_1, \ldots, p_m) \right|^2
\]

\[
\cos(\omega + \sum_{l=1}^{m+1} \varepsilon_{k_l} + \sum_{l=1}^{m} \varepsilon_{p_l})t - 1
\frac{1}{(\omega + \sum_{l=1}^{m} \varepsilon_{p_l} - \sum_{l=1}^{m+1} \varepsilon_{k_l})^2}
\]

\[
+ 2g^2 \sum_{p_1 < \ldots < p_{m+2}} \left| f(p_1, \ldots, p_{m+2}; k_1, \ldots, k_{m+1}) \right|^2
\]

\[
\cos(\omega + \sum_{l=1}^{m+2} \varepsilon_{p_l} - \sum_{l=1}^{m+1} \varepsilon_{k_l})t - 1
\frac{1}{(\omega + \sum_{l=1}^{m+1} \varepsilon_{p_l} - \sum_{l=1}^{m+2} \varepsilon_{k_l})^2}.
\]

(62) with \(\alpha\) given by Eq. (44).

For short times \((\omega - \sum_{l=1}^{m+1} \varepsilon_{k_l} + \sum_{l=1}^{m} \varepsilon_{p_l})t, (\omega + \sum_{l=1}^{m+1} \varepsilon_{k_l} - \sum_{l=1}^{m+2} \varepsilon_{p_l})t \ll 1\), we have

\[
|r(t)|^2 \approx 1 - \alpha(gt)^2 \approx e^{-\alpha(gt)^2},
\]

(63)
