Abstract

This note presents sharp inequalities for deviation probability of a general quadratic form of a random vector $\xi$ with finite exponential moments. The obtained deviation bounds are similar to the case of a Gaussian random vector. The results are stated under general conditions and do not suppose any special structure of the vector $\xi$. The obtained bounds are exact (non-asymptotic), all constants are explicit and the leading terms in the bounds are sharp.

AMS 2000 Subject Classification: Primary 60F10. Secondary 62F10

Keywords: quadratic forms, deviation bounds

1 Introduction

This paper presents a number of deviation probability bounds for a quadratic form $\|\xi\|^2$ or more generally $\|B\xi\|^2$ of a random $p$ vector $\xi$ satisfying a general exponential moment condition. Such quadratic forms arise in many problems. We mainly focus on statistical applications such that hypothesis testing for linear models or linear model selection. We refer to Massart (2007) for an extensive overview and numerous results on

probability bounds and their applications in statistical model selection. Limit theorems for quadratic forms can be found e.g. in Götze and Tikhomirov (1999) and Horváth and Shao (1999). Some concentration bounds for U-statistics are available in Bretagnolle (1999), Giné et al. (2000), Houdré and Reynaud-Bouret (2003). We also refer to Baraud (2010) for a number of statistical problems relying on such deviation bounds.

If $\xi$ is standard normal then $\|\xi\|^2$ is chi-squared with $p$ degrees of freedom. We aim to extend this behavior to the case of a general vector $\xi$ satisfying the following exponential moment condition:

$$\log E \exp(\gamma^\top \xi) \leq \|\gamma\|^2/2, \quad \gamma \in \mathbb{R}^p, \|\gamma\| \leq g. \quad (1.1)$$

Here $g$ is a positive constant which appears to be very important in our results. Namely, it determines the frontier between the Gaussian and non-Gaussian type deviation bounds. Our first result shows that under (1.1) the deviation bounds for the quadratic form $\|\xi\|^2$ are essentially the same as in the Gaussian case, if the value $g^2$ exceed $Cp$ for a fixed constant $C$. Further we extend the result to the case of a more general form $\|B\xi\|^2$. An important advantage of the approach of this paper which differs it from all the previous studies is that there is no any additional conditions on the structure or origin of the vector $\xi$. For instance, we do not assume that $\xi$ is a sum of independent or weakly dependent random variables, or components of $\xi$ are independent. The results are exact stated in a non-asymptotic fashion, all the constants are explicit and the leading terms are sharp.

As a motivating example, we consider a linear regression model $Y = \Psi^\top \theta + \varepsilon$ in which the error vector $\varepsilon$ is zero mean. The ordinary least square estimator $\tilde{\theta}$ for the parameter vector $\theta$ reads as

$$\tilde{\theta} = (\Psi\Psi^\top)^{-1}\Psi Y$$

and it can be viewed as the maximum likelihood estimator in a Gaussian linear model with a diagonal covariance matrix, that is, $Y \sim N(\Psi^\top \theta, \sigma^2 I_n)$. Define the $p \times p$ matrix

$$D_0^2 \overset{\text{def}}{=} \Psi\Psi^\top,$$

Then

$$D_0(\tilde{\theta} - \theta^*) = D_0^{-1}\zeta$$

with $\zeta \overset{\text{def}}{=} \Psi Y$. The likelihood ratio test statistic for this problem is exactly $\|D_0^{-1}\zeta\|^2/2$. Similarly, the model selection procedure is based on comparing such quadratic forms for different matrices $D_0$; see e.g. Baraud (2010).
Now we indicate how this situation can be reduced to a bound for a vector $\xi$ satisfying the condition (1.1). Suppose for simplicity that the errors $\varepsilon_i$ are independent and have exponential moments.

$$(e_1) \quad \text{There exist some constants } \nu_0 \text{ and } g_1 > 0, \text{ and for every } i \text{ a constant } s_i \text{ such that } \mathbb{E}(\varepsilon_i/s_i)^2 \leq 1 \text{ and}$$

$$\log \mathbb{E} \exp(\lambda \varepsilon_i/s_i) \leq \nu_0 \lambda^2/2, \quad |\lambda| \leq g_1. \quad (1.2)$$

Here $g_1$ is a fixed positive constant. One can show that if this condition is fulfilled for some $g_1 > 0$ and a constant $\nu_0 \geq 1$, then one can get a similar condition with $\nu_0$ arbitrary close to one and $g_1$ slightly decreased. A natural candidate for $s_i$ is $\sigma_i$ where $\sigma_i^2 = \mathbb{E}\varepsilon_i^2$ is the variance of $\varepsilon_i$. Under (1.2), introduce a $p \times p$ matrix $V_0$ defined by

$$V_0^2 \overset{\text{def}}{=} \sum s_i^2 \psi_i \psi_i^\top.$$

Define also

$$\xi = V_0^{-1} \psi Y,$$

$$N^{-1/2} \overset{\text{def}}{=} \max_i \sup_{\gamma \in \mathbb{R}^p} \frac{s_i |\psi_i^\top \gamma|}{\|V_0 \gamma\|}.$$

Simple calculation shows that for $\|\gamma\| \leq g = g_1 N^{1/2}$

$$\log \mathbb{E} \exp(\gamma^\top \xi) \leq \nu_0^2 \|\gamma\|^2/2, \quad \gamma \in \mathbb{R}^p, \|\gamma\| \leq g.$$ 

We conclude that (1.1) is nearly fulfilled under $(e_1)$ and moreover, the value $g^2$ is proportional to the effective sample size $N$. The results of the paper allow to get a nearly $\chi^2$-behavior of the test statistic $\|\xi\|^2$ which is a finite sample version of the famous Wilks phenomenon; see e.g. Fan et al. (2001); Fan and Huang (2005), Boucheron and Massart (2011).

The paper is organized as follows. Section 2 reminds the classical results about deviation probability of a Gaussian quadratic form. These results are presented only for comparison and to make the paper self-contained.

Section 3 studies the probability of the form $\mathcal{H}(\|\xi\| > y)$ under the condition

$$\log \mathbb{E} \exp(\gamma^\top \xi) \leq \nu_0^2 \|\gamma\|^2/2, \quad \gamma \in \mathbb{R}^p, \|\gamma\| \leq g.$$ 

The general case can be reduced to $\nu_0 = 1$ by rescaling $\xi$ and $g$:

$$\log \mathbb{E} \exp(\gamma^\top \xi/\nu_0) \leq \|\gamma\|^2/2, \quad \gamma \in \mathbb{R}^p, \|\gamma\| \leq \nu_0 g.$$
that is, $\nu_0^{-1}\xi$ fulfills (1.1) with a slightly increased $g$.

The result is extended to the case of a general quadratic form in Section 4. Some more extension motivated by different statistical problems are given in Section 6 and Section 7. All the proofs are collected in the Appendix.

2 Gaussian case

Our benchmark will be a deviation bound for $\|\xi\|_2$ for a standard Gaussian vector $\xi$. The ultimate goal is to show that under (1.1) the norm of the vector $\xi$ exhibits behavior expected for a Gaussian vector, at least in the region of moderate deviations. For the reason of comparison, we begin by stating the result for a Gaussian vector $\xi$.

**Theorem 2.1.** Let $\xi$ be a standard normal vector in $\mathbb{R}^p$. Then for any $u > 0$, it holds

$$P(\|\xi\|^2 > p + u) \leq \exp\{-(p/2)\phi(u/p)\}$$

with

$$\phi(t) \text{ def } t - \log(1 + t).$$

Let $\phi^{-1}(\cdot)$ stand for the inverse of $\phi(\cdot)$. For any $x$,

$$P(\|\xi\|^2 > p + \phi^{-1}(2x/p)) \leq \exp(-x).$$

This particularly yields with $x = 6.6$

$$P(\|\xi\|^2 > p + \sqrt{2x^2} \vee (6a^*x)) \leq \exp(-x).$$

This is a simple version of a well known result and we present it only for comparison with the non-Gaussian case. The message of this result is that the squared norm of the Gaussian vector $\xi$ concentrates around the value $p$ and the deviation over the level $p + \sqrt{2x^2}$ are exponentially small in $x$.

A similar bound can be obtained for a norm of the vector $B\xi$ where $B$ is some given matrix. For notational simplicity we assume that $B$ is symmetric. Otherwise one should replace it with $(B^T B)^{1/2}$.

**Theorem 2.2.** Let $\xi$ be standard normal in $\mathbb{R}^p$. Then for every $x > 0$ and any symmetric matrix $B$, it holds with $p = \text{tr}(B^2)$, $v^2 = 2\text{tr}(B^4)$, and $a^* = \|B^2\|_\infty$

$$P(\|B\xi\|^2 > p + (2vx^{1/2}) \vee (6a^*x)) \leq \exp(-x).$$

Below we establish similar bounds for a non-Gaussian vector $\xi$ obeying (1.1).
3 A bound for the $\ell_2$-norm

This section presents a general exponential bound for the probability $\mathbb{P}(\|\xi\| > y)$ under (1.1). The main result tells us that if $y$ is not too large, namely if $y \leq y_c$ with $y_c^2 \asymp g^2$, then the deviation probability is essentially the same as in the Gaussian case.

To describe the value $y_c$, introduce the following notation. Given $g$ and $p$, define the values $w_0 = g p - 1/2$ and $w_c$ by the equation

$$
\frac{w_c(1 + w_c)}{(1 + w_c^2)^{1/2}} = w_0 = g p^{-1/2}. \tag{3.1}
$$

It is easy to see that $w_0/\sqrt{2} \leq w_c \leq w_0$. Further define

$$
\begin{align*}
\mu_c &\overset{\text{def}}{=} w_c^2/(1 + w_c^2) \\
y_c &\overset{\text{def}}{=} \sqrt{(1 + w_c^2)p} \\
x_c &\overset{\text{def}}{=} 0.5 p [w_c^2 - \log(1 + w_c^2)]. \tag{3.2}
\end{align*}
$$

Note that for $g^2 \geq p$, the quantities $y_c$ and $x_c$ can be evaluated as $y_c^2 \geq w_c^2 p \geq g^2 / 2$ and $x_c \geq p w_c^2 / 2 \geq g^2 / 4$.

**Theorem 3.1.** Let $\xi \in \mathbb{R}^p$ fulfill (1.1). Then it holds for each $x \leq x_c$

$$
\mathbb{P}(\|\xi\|^2 > p + \sqrt{x}xp \vee (\sqrt{x}x), \|\xi\| \leq y_c) \leq 2 \exp(-x),
$$

where $\kappa = 6.6$. Moreover, for $y \geq y_c$, it holds with $g_c = g - \sqrt{\mu_c p} = gw_c/(1 + w_c)$

$$
\begin{align*}
\mathbb{P}(\|\xi\| > y) &\leq 8.4 \exp\left\{-g_c y/2 - (p/2) \log(1 - g_c/y)\right\} \\
&\leq 8.4 \exp\left\{-x_c - g_c (y - y_c)/2\right\}.
\end{align*}
$$

The statements of Theorem 4.1 can be simplified under the assumption $g^2 \geq p$.

**Corollary 3.2.** Let $\xi$ fulfill (1.1) and $g^2 \geq p$. Then it holds for $x \leq x_c$

$$
\mathbb{P}(\|\xi\|^2 \geq \tilde{z}(x, p)) \leq 2 e^{-x} + 8.4 e^{-x_c}, \tag{3.3}
$$

$$
\tilde{z}(x, p) \overset{\text{def}}{=} \begin{cases}
 p + \sqrt{x}xp, & x \leq p/\kappa, \\
p + \kappa x & p/\kappa < x \leq x_c,
\end{cases} \tag{3.4}
$$

with $\kappa = 6.6$. For $x > x_c$

$$
\mathbb{P}(\|\xi\|^2 \geq \tilde{z}_c(x, p)) \leq 8.4 e^{-x}, \quad \tilde{z}_c(x, p) \overset{\text{def}}{=} |y_c + 2(x - x_c)/g_c|^2.
$$
This result implicitly assumes that \( p \leq \gamma x_c \) which is fulfilled if \( \gamma w_0^2 = g^2/p \geq 1 \):
\[
\gamma x_c = 0.5 \gamma [w_0^2 - \log(1 + w_0^2)]p \geq 3.3 [1 - \log(2)]p > p.
\]
For \( x \leq x_c \), the function \( z(x, p) \) mimics the quantile behavior of the chi-squared distribution \( \chi^2_p \) with \( p \) degrees of freedom. Moreover, increase of the value \( g \) yields a growth of the sub-Gaussian zone. In particular, for \( g = \infty \), a general quadratic form \( \|\xi\|^2 \) has under (1.1) the same tail behavior as in the Gaussian case.

Finally, in the large deviation zone \( x > x_c \) the deviation probability decays as \( e^{-cx^{1/2}} \) for some fixed \( c \). However, if the constant \( g \) in the condition (1.1) is sufficiently large relative to \( p \), then \( x_c \) is large as well and the large deviation zone \( x > x_c \) can be ignored at a small price of \( 8.4e^{-x_c} \) and one can focus on the deviation bound described by (3.3) and (3.4).

4 A bound for a quadratic form

Now we extend the result to more general bound for \( \|B\xi\|^2 = \xi^\top B^2 \xi \) with a given matrix \( B \) and a vector \( \xi \) obeying the condition (1.1). Similarly to the Gaussian case we assume that \( B \) is symmetric. Define important characteristics of \( B \)
\[
p = \text{tr}(B^2), \quad v^2 = 2 \text{tr}(B^4), \quad \lambda^* \overset{\text{def}}{=} \|B^2\|_\infty \overset{\text{def}}{=} \lambda_{\max}(B^2).
\]
For simplicity of formulation we suppose that \( \lambda^* = 1 \), otherwise one has to replace \( p \) and \( v^2 \) with \( p/\lambda^* \) and \( v^2/\lambda^* \).

Let \( g \) be shown in (1.1). Define similarly to the \( \ell_2 \)-case \( w_c \) by the equation
\[
\frac{w_c(1 + w_c)}{(1 + w_c^2)^{1/2}} = gp^{-1/2}.
\]
Define also \( \mu_c = \frac{w_c^2}{(1 + w_c^2)} \wedge 2/3 \). Note that \( w_c^2 \geq 2 \) implies \( \mu_c = 2/3 \). Further define
\[
y_c^2 = (1 + w_c^2)p, \quad 2x_c = \mu_c y_c^2 + \log \det(I_p - \mu_c B^2).
\]
Similarly to the case with \( B = I_p \), under the condition \( g^2 \geq p \), one can bound \( y_c^2 \geq g^2/2 \) and \( x_c \geq g^2/4 \).

**Theorem 4.1.** Let a random vector \( \xi \) in \( \mathbb{R}^p \) fulfill (1.1). Then for each \( x < x_c \)
\[
\mathbb{P}(\|B\xi\| > p + (2v^2)^{1/2} \lor (6x), \|B\xi\| \leq y_c) \leq 2 \exp(-x).
\]
Moreover, for \( y \geq y_c \), with \( g_c = g - \sqrt{\mu_c}p = g w_c/(1 + w_c) \), it holds
\[
\mathbb{P}(\|B\xi\| > y) \leq 8.4 \exp(-x_c - g_c(y - y_c)/2).
\]
Now we describe the value $\zeta(x, \mathcal{B})$ ensuring a small value for the large deviation probability $P(\|\mathcal{B}\xi\|^2 \geq \zeta(x, \mathcal{B}))$. For ease of formulation, we suppose that $g^2 \geq 2p$ yielding $\mu_c^{-1} \leq 3/2$. The other case can be easily adjusted.

**Corollary 4.2.** Let $\xi$ fulfill (1.1) with $g^2 \geq 2p$. Then it holds for $x \leq x_c$ with $x_c$ from (4.1):

$$P(\|\mathcal{B}\xi\|^2 \geq \zeta(x, \mathcal{B})) \leq 2e^{-x} + 8.4e^{-x_c},$$

$$\zeta(x, \mathcal{B}) \overset{\text{def}}{=} \begin{cases} p + 2vx^1/2, & x \leq v/18, \\ p + 6x & v/18 < x \leq x_c. \end{cases} \quad (4.2)$$

For $x > x_c$

$$P(\|\mathcal{B}\xi\|^2 \geq \zeta_c(x, \mathcal{B})) \leq 8.4e^{-x}, \quad \zeta_c(x, \mathcal{B}) \overset{\text{def}}{=} |y_c + 2(x - x_c)/g_c|^2.$$

### 5 Rescaling and regularity condition

The result of Theorem 4.1 can be extended to a more general situation when the condition (1.1) is fulfilled for a vector $\zeta$ rescaled by a matrix $V_0$. More precisely, let the random $p$-vector $\zeta$ fulfills for some $p \times p$ matrix $V_0$ the condition

$$\sup_{\gamma \in \mathbb{R}^p} \log E \exp \left( \frac{\gamma^T \zeta}{\|V_0\gamma\|} \right) \leq \nu_0^2 \lambda^2 / 2, \quad |\lambda| \leq g, \quad (5.1)$$

with some constants $g > 0, \nu_0 \geq 1$. Again, a simple change of variables reduces the case of an arbitrary $\nu_0 \geq 1$ to $\nu_0 = 1$. Our aim is to bound the squared norm $\|D_0^{-1}\zeta\|^2$ of a vector $D_0^{-1}\zeta$ for another $p \times p$ positive symmetric matrix $D_0^2$. Note that condition (5.1) implies (1.1) for the rescaled vector $\xi = V_0^{-1}\zeta$. This leads to bounding the quadratic form $\|D_0^{-1}V_0\xi\|^2 = \|\mathcal{B}\xi\|^2$ with $\mathcal{B}^2 = D_0^{-1}V_0D_0^{-1}$. It obviously holds

$$p = \text{tr}(\mathcal{B}^2) = \text{tr}(D_0^{-2}V_0^2).$$

Now we can apply the result of Corollary 4.2.

**Corollary 5.1.** Let $\zeta$ fulfill (5.1) with some $V_0$ and $g$. Given $D_0$, define $\mathcal{B}^2 = D_0^{-1}V_0^2D_0^{-1}$, and let $g^2 \geq 2p$. Then it holds for $x \leq x_c$ with $x_c$ from (4.1):

$$P(\|D_0^{-1}\zeta\|^2 \geq \zeta(x, \mathcal{B})) \leq 2e^{-x} + 8.4e^{-x_c},$$

with $\zeta(x, \mathcal{B})$ from (4.2). For $x > x_c$

$$P(\|D_0^{-1}\zeta\|^2 \geq \zeta_c(x, \mathcal{B})) \leq 8.4e^{-x}, \quad \zeta_c(x, \mathcal{B}) \overset{\text{def}}{=} |y_c + 2(x - x_c)/g_c|^2.$$
In the regular case with $D_0 \geq aV_0$ for some $a > 0$, one obtains $\|IB\|_\infty \leq a^{-1}$ and 
\[ v^2 = 2 \text{tr}(IB^4) \leq 2a^{-2}p. \]

6 A chi-squared bound with norm-constraints

This section extends the results to the case when the bound (1.1) requires some other conditions than the $\ell_2$-norm of the vector $\gamma$. Namely, we suppose that
\[ \log \mathbb{E} \exp(\gamma^\top \xi) \leq \|\gamma\|^2/2, \quad \gamma \in \mathbb{R}^p, \|\gamma\|_o \leq g_o, \] (6.1)
where $\|\cdot\|_o$ is a norm which differs from the usual Euclidean norm. Our driving example is given by the sup-norm case with $\|\gamma\|_o \equiv \|\gamma\|_\infty$. We are interested to check whether the previous results of Section 3 still apply. The answer depends on how massive the set $A(r) = \{\gamma : \|\gamma\|_o \leq r\}$ is in terms of the standard Gaussian measure on $\mathbb{R}^p$. Recall that the quadratic norm $\|\epsilon\|^2$ of a standard Gaussian vector $\epsilon$ in $\mathbb{R}^p$ concentrates around $p$ at least for $p$ large. We need a similar concentration property for the norm $\|\cdot\|_o$.

More precisely, we assume for a fixed $r_*$ that
\[ \mathbb{P}(\|\epsilon\|_o \leq r_*) \geq 1/2, \quad \epsilon \sim \mathcal{N}(0, I_p). \] (6.2)
This implies for any value $u_o > 0$ and all $u \in \mathbb{R}^p$ with $\|u\|_o \leq u_o$ that
\[ \mathbb{P}(\|\epsilon - u\|_o \leq r_* + u_o) \geq 1/2, \quad \epsilon \sim \mathcal{N}(0, I_p). \]

For each $z > p$, consider
\[ \mu(z) = (z - p)/z. \]

Given $u_o$, denote by $z_o = z_o(u_o)$ the root of the equation
\[ \frac{g_o}{\mu(z_o)} - \frac{r_*}{\mu^{1/2}(z_o)} = u_o. \] (6.3)

One can easily see that this value exists and unique if $u_o \geq g_o - r_*$ and it can be defined as the largest $z$ for which $\frac{g_o}{\mu(z)} - \frac{r_*}{\mu^{1/2}(z)} \geq u_o$. Let $\mu_o = \mu(z_o)$ be the corresponding $\mu$-value. Define also $x_o$ by
\[ 2x_o = \mu_o z_o + p \log(1 - \mu_o). \]

If $u_o < g_o - r_*$, then set $z_o = \infty$, $x_o = \infty$. 

8 SHARP DEVIATION BOUNDS FOR QUADRATIC FORMS
Theorem 6.1. Let a random vector $\xi$ in $\mathbb{R}^p$ fulfill (6.1). Suppose (6.2) and let, given $u_0$, the value $z_o$ be defined by (6.3). Then it holds for any $u > 0$

$$
\mathbb{P}(\|\xi\|^2 > p + u, \|\xi\|_0 \leq u_0) \leq 2 \exp \left\{ -(p/2) \phi(u) \right\}.
$$

(6.4)
yielding for $x \leq x_o$

$$
\mathbb{P}(\|\xi\|^2 > p + \sqrt{\exp \left( \kappa x \right) \vee (\kappa x)}, \|\xi\|_0 \leq u_0) \leq 2 \exp(-x),
$$

(6.5)
where $\kappa = 6.6$. Moreover, for $z \geq z_o$, it holds

$$
\mathbb{P}(\|\xi\|^2 > z, \|\xi\|_0 \leq u_0) \leq 2 \exp \left\{ -\mu_o z / 2 - (p/2) \log(1 - \mu_o) \right\} = 2 \exp \left\{ -x_o - g_o \left( z - z_o \right) / 2 \right\}.
$$

It is easy to check that the result continues to hold for the norm of $\Pi \xi$ for a given sub-projector $\Pi$ in $\mathbb{R}^p$ satisfying $\Pi = \Pi^\top$, $\Pi^2 \leq \Pi$. As above, denote $p \defeq \text{tr}(\Pi^2)$, $v^2 \defeq 2 \text{tr}(\Pi^4)$. Let $r_*$ be fixed to ensure

$$
\mathbb{P}(\|\Pi \varepsilon\|_0 \leq r_*) \geq 1/2, \quad \varepsilon \sim N(0, I_p).
$$

The next result is stated for $g_o \geq r_* + u_o$, which simplifies the formulation.

Theorem 6.2. Let a random vector $\xi$ in $\mathbb{R}^p$ fulfill (6.1) and $\Pi$ follows $\Pi = \Pi^\top$, $\Pi^2 \leq \Pi$. Let some $u_0$ be fixed. Then for any $\mu_o \leq 2/3$ with $g_o \mu_o^{-1} - r_* \mu_o^{-1/2} \geq u_o$,

$$
\mathbb{E} \exp \left\{ \frac{\mu_o}{2} (\|\Pi \xi\|^2 - p) \right\} \mathbb{I}(\|\Pi^2 \xi\|_0 \leq u_0) \leq 2 \exp(\mu_o^2 v^2 / 4),
$$

(6.6)
where $v^2 = 2 \text{tr}(\Pi^4)$. Moreover, if $g_o \geq r_* + u_o$, then for any $z \geq 0$

$$
\mathbb{P}(\|\Pi \xi\|^2 > z, \|\Pi^2 \xi\|_0 \leq u_0)
\leq \mathbb{P}(\|\Pi \xi\|^2 > p + (2v \kappa)^{1/2} \vee (\kappa x), \|\Pi^2 \xi\|_0 \leq u_0) \leq 2 \exp(-x).
$$

7 A bound for the $\ell_2$-norm under Bernstein conditions

For comparison, we specify the results to the case considered recently in Baraud (2010). Let $\zeta$ be a random vector in $\mathbb{R}^n$ whose components $\zeta_i$ are independent and satisfy the Bernstein type conditions: for all $|\lambda| < c^{-1}$

$$
\log \mathbb{E} e^{\lambda \zeta_i} \leq \frac{\lambda^2 \sigma^2}{1 - c|\lambda|}.
$$

(7.1)
Denote $\xi = \zeta / (2\sigma)$ and consider $\|\gamma\|_o = \|\gamma\|_\infty$. Fix $g_0 = \sigma / c$. If $\|\gamma\|_o \leq g_0$, then $1 - c\gamma_i / (2\sigma) \geq 1/2$ and
\[
\log \mathbb{E} \exp (\gamma^T \xi) \leq \sum_i \log \mathbb{E} \exp \left( \frac{\gamma_i \zeta_i}{2 \sigma} \right) \leq \sum_i \frac{|\gamma_i / (2\sigma)|^2 \sigma^2}{1 - c\gamma_i / (2\sigma)} \leq \|\gamma\|^2 / 2.
\]

Let also $S$ be some linear subspace of $\mathbb{R}^n$ with dimension $p$ and $\Pi_S$ denote the projector on $S$. For applying the result of Theorem 6.1, the value $r_*$ has to be fixed. We use that the infinity norm $\|\varepsilon\|_\infty$ concentrates around $\sqrt{2 \log p}$.

**Lemma 7.1.** It holds for a standard normal vector $\varepsilon \in \mathbb{R}^p$ with $r = \sqrt{2 \log p}$
\[
\mathbb{P}(\|\varepsilon\|_o \leq r_*) \geq 1/2.
\]

**Proof.** By definition
\[
\mathbb{P}(\|\varepsilon\|_o > r) \leq \mathbb{P}(\|\varepsilon\|_\infty > \sqrt{2 \log p}) \leq \mathbb{P}(\|\varepsilon_1\| > \sqrt{2 \log p}) \leq 1/2
\]
as required.\[\square\]

Now the general bound of Theorem 6.1 is applied to bounding the norm of $\|\Pi_S \zeta\|$. For simplicity of formulation we assume that $g_0 \geq u_0 + r_*$.\[\]

**Theorem 7.2.** Let $S$ be some linear subspace of $\mathbb{R}^n$ with dimension $p$. Let $g_0 \geq u_0 + r_*$. If the coordinates $\zeta_i$ of $\zeta$ are independent and satisfy (7.1), then for all $x$,
\[
\mathbb{P}(4\sigma^2)^{-1} \|\Pi_S \zeta\|^2 > p + \sqrt{2\exp \left( \sqrt{2 \log p} \right)} \vee (\sqrt{x} + 3p), \quad \|\Pi_S \zeta\|_\infty \leq 2\sigma u_0 \leq 2 \exp(-x),
\]
\[
\mathbb{P}(\|\Pi_S \zeta\|_2 > (3 \sigma \vee \sqrt{6c}u) \sqrt{x + 3p}, \quad \|\Pi_S \zeta\|_\infty \leq 2\sigma u_0 \leq \exp(-x).
\]

The bound of Baraud (2010) reads
\[
\mathbb{P}(\|\Pi_S \zeta\|_2 > (3 \sigma \vee \sqrt{6c}u) \sqrt{x + 3p}, \quad \|\Pi_S \zeta\|_\infty \leq 2\sigma u_0 \leq \exp(-x).
\]

As expected, in the region $x \leq x_c$ of Gaussian approximation, the bound of Baraud is not sharp and actually quite rough.

**A Proof of Theorem 2.1**

The proof utilizes the following well known fact: for $\mu < 1$
\[
\log \mathbb{E} \exp (\mu \|\xi\|^2 / 2) = -0.5p \log (1 - \mu).
\]
It can be obtained by straightforward calculus. Now consider any $u > 0$. By the exponential Chebyshev inequality

$$
\mathbb{P}\left(\|\xi\|^2 > p + u\right) \leq \exp\left\{-\mu(p + u)/2\right\} \mathbb{E}\left\{\exp\left(\mu||\xi\||^2/2\right)\right\}
$$

(A.1)

$$
= \exp\left\{-\mu(p + u)/2 - (p/2)\log(1 - \mu)\right\}.
$$

It is easy to see that the value $\mu = u/(u + p)$ maximizes $\mu(p + u) + p\log(1 - \mu)$ w.r.t. $\mu$ yielding

$$
\mu(p + u) - p\log(1 - \mu) = u - p\log(1 + u/p).
$$

Further we use that $x - \log(1 + x) \geq a_0 x^2$ for $x \leq 1$ and $x - \log(1 + x) \geq a_0 x$ for $x > 1$ with $a_0 = 1 - \log(2) \geq 0.3$. This implies with $u = \sqrt{\kappa p}$ or $u = \kappa x$ and $\kappa = 2/a_0 < 6.6$ that

$$
\mathbb{P}\left(\|\xi\|^2 \geq p + \sqrt{\kappa p} \vee (\kappa x)\right) \leq \exp(-x)
$$

as required.

## B Proof of Theorem 2.2

The matrix $\mathbb{B}^2$ can be represented as $U^\top \text{diag}(a_1, \ldots, a_p)U$ for an orthogonal matrix $U$. The vector $\tilde{\xi} = U\xi$ is also standard normal and $\|\mathbb{B}\xi\|^2 = \tilde{\xi}^\top \mathbb{B}^2 U^\top \tilde{\xi}$. This means that one can reduce the situation to the case of a diagonal matrix $\mathbb{B}^2 = \text{diag}(a_1, \ldots, a_p)$.

We can also assume without loss of generality that $a_1 \geq a_2 \geq \ldots \geq a_p$. The expressions for the quantities $p$ and $v^2$ simplifies to

$$
p = \text{tr}(\mathbb{B}^2) = a_1 + \ldots + a_p,
$$

$$
v^2 = 2\text{tr}(\mathbb{B}^4) = 2(a_1^2 + \ldots + a_p^2).
$$

Moreover, rescaling the matrix $\mathbb{B}^2$ by $a_1$ reduces the situation to the case with $a_1 = 1$.

**Lemma B.1.** It holds

$$
\text{Var}(\|\mathbb{B}\xi\|^2) = 2\text{tr}(\mathbb{B}^4).
$$

Moreover, for $\mu < 1$

$$
\mathbb{E}\exp\left\{\mu\|\mathbb{B}\xi\|^2/2\right\} = \det(1 - \mu\mathbb{B}^2)^{-1/2} = \prod_{i=1}^{p}(1 - \mu a_i)^{-1/2}. \quad (B.1)
$$
Proof. If $B^2$ is diagonal, then $\|B\xi\|^2 = \sum_i a_i \xi^2_i$ and the summands $a_i \xi^2_i$ are independent. It remains to note that $\mathbb{E}(a_i \xi^2_i) = a_i$, $\text{Var}(a_i \xi^2_i) = 2a_i^2$, and for $\mu a_i < 1$,

$$\mathbb{E} \exp\{\mu a_i \xi^2_i / 2\} = (1 - \mu a_i)^{-1/2}$$

yielding (B.1). \qed

Given $u$, fix $\mu < 1$. The exponential Markov inequality yields

$$\mathbb{P}(\|B\xi\|^2 > p + u) \leq \exp\{-\mu(p + u)\} \mathbb{E} \exp\left(\frac{\mu \|B\xi\|^2}{2}\right)$$

$$\leq \exp\left\{-\frac{\mu u}{2} - \frac{1}{2} \sum_{i=1}^p [\mu a_i + \log(1 - \mu a_i)]\right\}.$$  

We start with the case when $x^{1/2} \leq v/3$. Then $u = 2x^{1/2}v$ fulfills $u \leq 2v^2/3$. Define $\mu = u/v^2 \leq 2/3$ and use that $t + \log(1 - t) \geq -t^2$ for $t \leq 2/3$. This implies

$$\mathbb{P}(\|B\xi\|^2 > p + u)$$

$$\leq \exp\left\{-\frac{\mu u}{2} + \frac{1}{2} \sum_{i=1}^p \mu^2 a_i^2\right\} = \exp(-u^2/(4v^2)) = e^{-x}. \quad (B.2)$$

Next, let $x^{1/2} > v/3$. Set $\mu = 2/3$. It holds similarly to the above

$$\sum_{i=1}^p [\mu a_i + \log(1 - \mu a_i)] \geq -\sum_{i=1}^p \mu^2 a_i^2 \geq -2v^2/9 \geq -2x.$$  

Now, for $u = 6x$ and $\mu u/2 = 2x$, (B.2) implies

$$\mathbb{P}(\|B\xi\|^2 > p + u) \leq \exp\{-2x - x\} = \exp(-x)$$

as required.

C Proof of Theorem 3.1

The main step of the proof is the following exponential bound.

Lemma C.1. Suppose (1.1). For any $\mu < 1$ with $g^2 > p\mu$, it holds

$$\mathbb{E} \exp\left(\frac{\mu \|\xi\|^2}{2}\right) \mathbb{I}\left(\|\xi\| \leq g/\mu - \sqrt{p/\mu}\right) \leq 2(1 - \mu)^{-p/2}. \quad (C.1)$$

Proof. Let $\varepsilon$ be a standard normal vector in $\mathbb{R}^p$ and $u \in \mathbb{R}^p$. The bound $\mathbb{P}(\|\varepsilon\|^2 > p) \leq 1/2$ implies for any vector $u$ and any $x$ with $x \geq \|u\| + p^{1/2}$ that $\mathbb{P}(\|u + \varepsilon\| \leq 2(1 - \mu)^{-p/2}$. 

Let us fix some $\xi$ with $\|\xi\| \leq \frac{g}{\mu} - \sqrt{p/\mu}$ and denote by $\mathbb{P}_\xi$ the conditional probability given $\xi$. It holds with $c_p = (2\pi)^{-p/2}$

$$c_p \int \exp\left(\gamma^\top \xi - \frac{\|\gamma\|^2}{2\mu}\right) \mathbb{I}(\|\gamma\| \leq g) d\gamma$$

$$= c_p \exp(\mu\|\xi\|^2/2) \int \exp\left(-\frac{1}{2}\|\mu^{-1/2} \gamma - \mu^{1/2} \xi\|^2\right) \mathbb{I}(\mu^{-1/2} \|\gamma\| \leq \mu^{-1/2} g) d\gamma$$

$$= \mu^{p/2} \exp(\mu\|\xi\|^2/2) \mathbb{P}_\xi(\|\xi + \mu^{1/2} \xi\| \leq \mu^{-1/2} g)$$

$$\geq 0.5 \mu^{p/2} \exp(\mu\|\xi\|^2/2),$$

because $\|\mu^{1/2} \xi\| + p^{1/2} \leq \mu^{-1/2} g$. This implies in view of $p < g^2/\mu$ that

$$\exp(\mu\|\xi\|^2/2) \mathbb{I}(\|\xi\|^2 \leq \frac{g}{\mu} - \sqrt{p/\mu}) \leq 2 \mu^{-p/2} c_p \int \exp\left(\gamma^\top \xi - \frac{\|\gamma\|^2}{2\mu}\right) \mathbb{I}(\|\gamma\| \leq g) d\gamma.$$}

Further, by (1.1)

$$c_p \mathbb{E} \int \exp\left(\gamma^\top \xi - \frac{1}{2\mu} \|\gamma\|^2\right) \mathbb{I}(\|\gamma\| \leq g) d\gamma$$

$$\leq c_p \int \exp\left(-\frac{\mu^{-1} - 1}{2} \|\gamma\|^2\right) \mathbb{I}(\|\gamma\| \leq g) d\gamma$$

$$\leq c_p \int \exp\left(-\frac{\mu^{-1} - 1}{2} \|\gamma\|^2\right) d\gamma$$

$$\leq (\mu^{-1} - 1)^{-p/2}$$

and (C.1) follows.

Due to this result, the scaled squared norm $\mu\|\xi\|^2/2$ after a proper truncation possesses the same exponential moments as in the Gaussian case. A straightforward implication is the probability bound $\mathbb{P}(\|\xi\|^2 > p + u)$ for moderate values $u$. Namely, given $u > 0$, define $\mu = u/(u + p)$. This value optimizes the inequality (A.1) in the Gaussian case. Now we can apply a similar bound under the constraints $\|\xi\| \leq \frac{g}{\mu} - \sqrt{p/\mu}$. Therefore, the bound is only meaningful if $\sqrt{u + p} \leq \frac{g}{\mu} - \sqrt{p/\mu}$ with $\mu = u/(u + p)$, or, with $w = \sqrt{u/p} \leq w_e$; see (3.1).

The largest value $u$ for which this constraint is still valid, is given by $p + u = y_e^2$. 

\[ \square \]
Hence, (C.1) yields for $p + u \leq y_c^2$

$$P(\|\xi\|^2 > p + u, \|\xi\| \leq y_c)$$

$$\leq \exp\left\{-\frac{\mu(p+u)}{2}\right\} I E \exp\left(\frac{\mu\|\xi\|^2}{2}\right) I(\|\xi\| \leq g/\mu - \sqrt{p/\mu})$$

$$\leq 2 \exp\{-0.5[\mu(p+u) + p \log(1 - \mu)]\}$$

$$= 2 \exp\{-0.5[u - p \log(1 + u/p)]\}. \tag{C.2}$$

Similarly to the Gaussian case, this implies with $x = 6.6$ that

$$P(\|\xi\| \geq p + \sqrt{2x}p \vee (\infty), \|\xi\| \leq y_c) \leq 2 \exp(-x). \tag{C.3}$$

The Gaussian case means that (1.1) holds with $g = \infty$ yielding $y_c = \infty$. In the non-Gaussian case with a finite $g$, we have to accompany the moderate deviation bound with a large deviation bound $P(\|\xi\| > y)$ for $y \geq y_c$. This is done by combining the bound (C.1) with the standard slicing arguments.

**Lemma C.2.** Let $\mu_0 \leq g^2/p$. Define $y_0 = g/\mu_0 - \sqrt{p/\mu_0}$ and $g_0 = \mu_0 y_0 = g - \sqrt{\mu_0 p}$. It holds for $y \geq y_0$

$$P(\|\xi\| > y) \leq 8.4(1 - g_0/y)^{-p/2} \exp(-g_0 y/2)$$

$$\leq 8.4 \exp\{-x_0 - g_0(y - y_0)/2\}. \tag{C.3}$$

with $x_0$ defined by

$$2x_0 = \mu_0 y_0^2 + p \log(1 - \mu_0) = g^2/\mu_0 - p + p \log(1 - \mu_0).$$

**Proof.** Consider the growing sequence $y_k$ with $y_1 = y$ and $g_0 y_{k+1} = g_0 y + k$. Define also $\mu_k = g_0/y_k$. In particular, $\mu_k \leq \mu_1 = g_0/y$. Obviously

$$P(\|\xi\| > y) = \sum_{k=1}^{\infty} P(\|\xi\| > y_k, \|\xi\| \leq y_{k+1}).$$

Now we try to evaluate every slicing probability in this expression. We use that

$$\mu_{k+1} y_k^2 = \frac{(g_0 y + k - 1)^2}{g_0 y + k} \geq g_0 y + k - 2,$$

and also $g/\mu_k - \sqrt{p/\mu_k} \geq y_k$ because $g - g_0 = \sqrt{\mu_0 p} > \sqrt{\mu_k p}$ and

$$g/\mu_k - \sqrt{p/\mu_k} - y_k = \mu_k^{-1}(g - \sqrt{\mu_k p} - g_0) \geq 0.$$
Hence by (C.1)

\[
P(\|\xi\| > y) \leq \sum_{k=1}^{\infty} P(\|\xi\| > y_k, \|\xi\| \leq y_{k+1}) \\
\leq \sum_{k=1}^{\infty} \exp\left( -\frac{\mu_{k+1}y^2_k}{2} \right) E \exp\left( \frac{\mu_{k+1}\|\xi\|^2}{2} \right) I(\|\xi\| \leq y_{k+1}) \\
\leq \sum_{k=1}^{\infty} 2(1 - \mu_{k+1})^{-p/2} \exp\left( -\frac{\mu_{k+1}y^2_k}{2} \right) \\
\leq 2(1 - \mu_1)^{-p/2} \sum_{k=1}^{\infty} \exp\left( -\frac{g_0y + k - 2}{2} \right) \\
= 2e^{1/2}(1 - e^{-1/2})^{-1}(1 - \mu_1)^{-p/2} \exp(-g_0y/2) \\
\leq 8.4(1 - \mu_1)^{-p/2} \exp(-g_0y/2)
\]

and the first assertion follows. For \( y = y_0 \), it holds

\[g_0y_0 + p \log(1 - \mu_0) = \mu_0y_0^2 + p \log(1 - \mu_0) = 2x_0\]

and (C.2) implies \( P(\|\xi\| > y_0) \leq 8.4 \exp(-x_0). \) Now observe that the function \( f(y) = g_0y/2 + (p/2) \log(1 - g_0/y) \) fulfills \( f(y_0) = x_0 \) and \( f'(y) \geq g_0/2 \) yielding \( f(y) \geq x_0 + g_0(y - y_0)/2. \) This implies (C.3).

The statements of the theorem are obtained by applying the lemmas with \( \mu_0 = \mu_c = w_c^2/(1 + w_c^2) \). This also implies \( y_0 = y_c, x_0 = x_c, \) and \( g_0 = g_c = g - \sqrt{\mu_c p}; \) cf. (3.2).

## D Proof of Theorem 4.1

The main steps of the proof are similar to the proof of Theorem 3.1.

**Lemma D.1.** Suppose (1.1). For any \( \mu < 1 \) with \( g^2/\mu \geq p \), it holds

\[
E \exp(\mu\|\mathcal{B}\xi\|^2/2) I(\|\mathcal{B}^2\xi\| \leq g/\mu - \sqrt{p/\mu}) \leq 2\det(I_p - \mu\mathcal{B}^2)^{-1/2}. \tag{D.1}
\]

**Proof.** With \( c_p(\mathcal{B}) = (2\pi)^{-p/2} \det(\mathcal{B}^{-1/2}) \)

\[
c_p(\mathcal{B}) \int \exp\left( \gamma^\top \xi - \frac{1}{2\mu} \|\mathcal{B}^{-1}\gamma\|^2 \right) I(\|\gamma\| \leq g) d\gamma \\
= c_p(\mathcal{B}) \exp(\mu\|\mathcal{B}\xi\|^2/2) \int \exp\left( -\frac{1}{2} \|\mu^{1/2}\mathcal{B}\xi - \mu^{-1/2}\mathcal{B}^{-1}\gamma\|^2 \right) I(\|\gamma\| \leq g) d\gamma \\
= \mu^{p/2} \exp(\mu\|\mathcal{B}\xi\|^2/2) P_\xi(\|\mu^{-1/2}\mathcal{B}\varepsilon + \mathcal{B}^2\xi\| \leq g/\mu),
\]
where \( \varepsilon \) denotes a standard normal vector in \( \mathbb{R}^p \) and \( P_\xi \) means the conditional probability given \( \xi \). Moreover, for any \( u \in \mathbb{R}^p \) and \( r \geq p^{1/2} + \| u \| \), it holds in view of \( P(\| B\varepsilon \|^2 > p) \leq 1/2 \)

\[
P(\| B\varepsilon - u \| \leq r) \geq P(\| B\varepsilon \| \leq \sqrt{p}) \geq 1/2.
\]

This implies

\[
\exp \left( \mu \| B\xi \|^2 / 2 \right) \mathbb{I}(\| B^2 \xi \| \leq g/\mu - \sqrt{p}/\mu) \leq 2\mu^{-p/2}c_p(B) \int \exp \left( \frac{\gamma^\top \xi - \| B^{-1} \gamma \|^2}{2\mu} \right) \mathbb{I}(\| \gamma \| \leq g) d\gamma.
\]

Further, by (1.1)

\[
c_p(B) \mathbb{E} \int \exp \left( \frac{\gamma^\top \xi - \| B^{-1} \gamma \|^2}{2\mu} \right) \mathbb{I}(\| \gamma \| \leq g) d\gamma \leq c_p(B) \int \exp \left( -\frac{\gamma^\top \xi - \| B^{-1} \gamma \|^2}{2\mu} \right) d\gamma \leq \det(B^{-1}) \det((\mu^{-1} B^{-2} - I_p)^{-1} = \mu^{p/2} \det(I_p - \mu B^2)^{-1/2}
\]

and (D.1) follows. \( \square \)

Now we evaluate the probability \( P(\| B\xi \|^2 > y) \) for moderate values of \( y \).

**Lemma D.2.** Let \( \mu_0 < 1 \wedge (g^2/p) \). With \( y_0 = g/\mu_0 - \sqrt{p}/\mu_0 \), it holds for any \( u > 0 \)

\[
P(\| B\xi \|^2 > p + u, \| B^2 \xi \| \leq y_0) \leq 2 \exp \left\{ -0.5 \mu_0 (p + u) - 0.5 \log \det(I_p - \mu_0 B^2) \right\}. \tag{D.2}
\]

In particular, if \( B^2 \) is diagonal, that is, \( B^2 = \text{diag}(a_1, \ldots, a_p) \), then

\[
P(\| B\xi \|^2 > p + u, \| B^2 \xi \| \leq y_0) \leq 2 \exp \left\{ -\frac{\mu_0 u}{2} - \frac{1}{2} \sum_{i=1}^p [\mu_0 a_i + \log (1 - \mu_0 a_i)] \right\}. \tag{D.3}
\]

**Proof.** The exponential Chebyshev inequality and (D.1) imply

\[
P(\| B\xi \|^2 > p + u, \| B^2 \xi \| \leq y_0) \leq \exp \left\{ -\frac{\mu_0 (p + u)}{2} \right\} \mathbb{E} \exp \left( \frac{\mu_0 \| B\xi \|^2}{2} \right) \mathbb{I}(\| B^2 \xi \| \leq g/\mu_0 - \sqrt{p}/\mu_0) \leq 2 \exp \left\{ -0.5 \mu_0 (p + u) - 0.5 \log \det(I_p - \mu_0 B^2) \right\}.
\]
Moreover, the standard change-of-basis arguments allow us to reduce the problem to the case of a diagonal matrix \( \mathbb{B}^2 = \text{diag}(a_1, \ldots, a_p) \) where \( 1 = a_1 \geq a_2 \geq \ldots \geq a_p > 0 \). Note that \( p = a_1 + \ldots + a_p \). Then the claim (D.2) can be written in the form (D.3).

Now we evaluate a large deviation probability that \( \|\mathbb{B}\xi\| > y \) for a large \( y \). Note that the condition \( \|\mathbb{B}^2\|_\infty \leq 1 \) implies \( \|\mathbb{B}^2\xi\| \leq \|\mathbb{B}\xi\| \). So, the bound (D.2) continues to hold when \( \|\mathbb{B}^2\xi\| \leq \gamma_0 \) is replaced by \( \|\mathbb{B}\xi\| \leq \gamma_0 \).

**Lemma D.3.** Let \( \mu_0 < 1 \) and \( \mu_0 p < g^2 \). Define \( g_0 \) by \( g_0 = g - \sqrt{\mu_0 p} \). For any \( y \geq \gamma_0 \), it holds

\[
\mathbb{P}(\|\mathbb{B}\xi\| > y) \leq 8.4 \text{det}\{I_p - (g_0/y)\mathbb{B}^2\}^{-1/2} \exp(-g_0y/2).
\]

where \( x_0 \) is defined by

\[
2x_0 = g_0\gamma_0 + \log \text{det}\{I_p - (g_0/\gamma_0)\mathbb{B}^2\}.
\]

**Proof.** The slicing arguments of Lemma C.2 apply here in the same manner. One has to replace \( \|\xi\| \) by \( \|\mathbb{B}\xi\| \) and \((1 - \mu_1)^{-p/2}\) by \( \text{det}\{I_p - (g_0/y)\mathbb{B}^2\}^{-1/2} \). We omit the details. In particular, with \( y = \gamma_0 = g_0/\mu \), this yields

\[
\mathbb{P}(\|\mathbb{B}\xi\| > \gamma_0) \leq 8.4 \exp(-x_0).
\]

Moreover, for the function \( f(y) = g_0\gamma_0 + \log \text{det}\{I_p - (g_0/y)\mathbb{B}^2\} \), it holds \( f'(y) \geq g_0 \) and hence, \( f(y) \geq f(\gamma_0) + g_0(\gamma_0 - \gamma_0) \) for \( y > \gamma_0 \). This implies (D.4).

One important feature of the results of Lemma D.2 and Lemma D.3 is that the value \( \mu_0 < 1 \wedge (g^2/p) \) can be selected arbitrarily. In particular, for \( y \geq \gamma_c \), Lemma D.3 with \( \mu_0 = \mu_c \) yields the large deviation probability \( \mathbb{P}(\|\mathbb{B}\xi\| > y) \). For bounding the probability \( \mathbb{P}(\|\mathbb{B}\xi\|^2 > p + u, \|\mathbb{B}\xi\| \leq \gamma_c) \), we use the inequality \( \log(1 - t) \geq -t - t^2 \) for \( t \leq 2/3 \). It implies for \( \mu \leq 2/3 \) that

\[
-\log \mathbb{P}(\|\mathbb{B}\xi\|^2 > p + u, \|\mathbb{B}\xi\| \leq \gamma_c)
\]

\[
\geq \mu(p + u) + \sum_{i=1}^{p} \log(1 - \mu a_i)
\]

\[
\geq \mu(p + u) - \sum_{i=1}^{p} (\mu a_i + \mu^2 a_i^2) \geq \mu u - \mu^2 v^2 / 2.
\]
Now we distinguish between \( \mu_c = 2/3 \) and \( \mu_c < 2/3 \) starting with \( \mu_c = 2/3 \). The bound (D.5) with \( \mu = 2/3 \) and with \( u = (2\nu x^{1/2}) \vee (6x) \) yields

\[
P(\|B\xi\|^2 > p + u, \|B\xi\| \leq y_c) \leq 2 \exp(-x);
\]
see the proof of Theorem 2.2 for the Gaussian case.

Now consider \( \mu_c < 2/3 \). For \( x^{1/2} \leq \mu_c \nu /2 \), use \( u = 2\nu x^{1/2} \) and \( u_0 = u /\nu^2 \). It holds \( u_0 = u /\nu^2 \leq \mu_c \) and \( w^2/(4\nu^2) = x \) yielding the desired bound by (D.5). For \( x^{1/2} > \mu_c \nu /2 \), we select again \( u_0 = \mu_c \). It holds with \( u = 4\mu_c^{-1}x \) that \( \mu_c u/2 - \mu_c^2 \nu^2 /4 \geq 2x - x = x \). This completes the proof.

### E Proof of Theorem 6.1

The arguments behind the result are the same as in the one-norm case of Theorem 3.1. We only outline the main steps.

**Lemma E.1.** Suppose (6.1) and (6.2). For any \( \mu < 1 \) with \( g_o > \mu^{1/2}r_\ast \), it holds

\[
\mathbb{E} \exp(\mu \|\xi\|^2 /2) \mathbb{I}(\|\xi\|_o \leq g_o / \mu - r_\ast / \mu^{1/2}) \leq 2(1 - \mu)^{-p/2}.
\]  

(E.1)

**Proof.** Let \( \varepsilon \) be a standard normal vector in \( \mathbb{R}^p \) and \( u \in \mathbb{R}^p \). Let us fix some \( \xi \) with \( \mu^{1/2}\|\xi\|_o \leq \mu^{-1/2}g_o - r_\ast \) and denote by \( \mathbb{P}_\xi \) the conditional probability given \( \xi \). It holds by (6.2) with \( c_p = (2\pi)^{-p/2} \)

\[
c_p \int \exp\left(\gamma^\top \xi - \frac{1}{2\mu} \|\gamma\|^2\right) \mathbb{I}(\|\gamma\|_o \leq g_o) d\gamma
\]

\[= c_p \exp(\mu \|\xi\|^2 /2) \int \exp\left(-\frac{1}{2} \|\mu^{1/2} \xi - \mu^{-1/2} \gamma\|^2\right) \mathbb{I}(\|\mu^{-1/2} \gamma\|_o \leq \mu^{-1/2}g_o) d\gamma
\]

\[= \mu^{p/2} \exp(\mu \|\xi\|^2 /2) \mathbb{P}_\xi(\|\varepsilon - \mu^{1/2} \xi\|_o \leq \mu^{-1/2}g_o)
\]

\[\geq 0.5 \mu^{p/2} \exp(\mu \|\xi\|^2 /2).
\]

This implies

\[
\exp\left(\frac{\mu \|\xi\|^2}{2}\right) \mathbb{I}(\|\xi\|_o \leq g_o / \mu - r_\ast / \mu^{1/2})
\]

\[\leq 2 \mu^{-p/2} c_p \int \exp\left(\gamma^\top \xi - \frac{1}{2\mu} \|\gamma\|^2\right) \mathbb{I}(\|\gamma\|_o \leq g_o) d\gamma.
\]

Further, by (6.1)

\[
c_p \mathbb{E} \int \exp\left(\gamma^\top \xi - \frac{1}{2\mu} \|\gamma\|^2\right) \mathbb{I}(\|\gamma\|_o \leq g_o) d\gamma
\]

\[\leq c_p \int \exp\left(-\frac{\mu - 1}{2} \|\gamma\|^2\right) d\gamma \leq (\mu^{-1} - 1)^{-p/2}
\]
and (E.1) follows.

As in the Gaussian case, (E.1) implies for $z > p$ with $\mu = \mu(z) = (z - p)/z$ the bounds (6.4) and (6.5). Note that the value $\mu(z)$ clearly grows with $z$ from zero to one, while $g_0/\mu(z) - r_s/\mu^{1/2}(z)$ is strictly decreasing. The value $\zeta_0$ is defined exactly as the point where $g_0/\mu(z) - r_s/\mu^{1/2}(z)$ crosses $u_0$, so that $g_0/\mu(z) - r_s/\mu^{1/2}(z) \geq u_0$ for $z \leq \zeta_0$.

For $z > \zeta_0$, the choice $\mu = \mu(y)$ conflicts with $g_0/\mu(z) - r_s/\mu^{1/2}(z) \geq u_0$. So, we apply $\mu = \mu_0$ yielding by the Markov inequality

$$
P(\|\xi\| > z, \|\xi\| \leq u_0) \leq 2 \exp\{-\mu_0 z/2 - (p/2) \log(1 - \mu_0)\},$$

and the assertion follows.

F Proof of Theorem 6.2

Arguments from the proof of Lemmas D.1 and E.1 yield in view of $g_0/\mu_0^{-1} - r_s/\mu_0^{-1/2} \geq u_0$

$$
\mathbb{E} \exp\{\mu_0 \|\Pi\xi\|^2/2\} \mathbb{I}(\|\Pi^2\xi\| \leq u_0)
\leq \mathbb{E} \exp\{\|\mu_0 \Pi\xi\|^2/2\} \mathbb{I}(\|\Pi^2\xi\| \leq g_0/\mu_0 - p/\mu_0^{1/2})
\leq 2 \det(I_p - \mu_0 \Pi^2)^{-1/2}.
$$

Now the inequality $\log(1 - t) \geq -t - t^2$ for $t \leq 2/3$ implies

$$
- \log \det(I_p - \mu_0 \Pi^2) \leq \mu_0 p + \mu_2 v^2/2
$$

cf. (D.5); the assertion (6.6) follows.
