Abstract. Metal-organic frameworks (MOFs) are a kind of porus materials, which has large specific surface area, high porosity, diverse structure, excellent thermal stability and solvent stability etc. So, it has attracted extensive attention as an adsorbent for solid phase extraction (SPE). Polycyclic aromatic hydrocarbons (PAHs) are a kind of persistent organic pollutants that can lead serious hurts to the ecological environment and human health. The purpose of this paper is to optimize the types and proportion of mixed lanthanum based MOFs, and to improve the enrichment efficiency of SPE. Then a method to analysis PAHs by SPE-HPLC was established. Several main factors that could effected the pre-treatment efficient, such as the amount of adsorbent, the amount and pH of PAHs water sample, and the volume of eluent, were investigated. After optimized, the extraction of seven PAHs in water sample was achieved and the recovery rates were 80.67%, 80.06%, 54.69%, 82.62%, 118.87%, 70.30% and 95.57% respectively.

1 Introduction

PAHs are a kind of strong carcinogens and are susceptible to bio-accumulation [1]. Increased human production activities have result in increased levels of PAHs in various environmental media, including the air, surface and ground water [2]. Since PAHs concentration in all kinds of environments is too low to detected by many popular analytical instruments. Therefore, a sample pre-treatment is necessary before chromatographic separation of PAHs in the environment, such as SPE, solid phase micro-extraction (SPME), cloud point extraction (CPE). SPE is the most popular method for the enrichment of various analytes in a variety of matrices, including biological, industrial, environmental and food samples [3, 4].

SPE technology was developed in the 1980s and proved to be the effective tool for the separation and purification of analytes [5]. The advantages of SPE include simplicity, flexibility, high selectivity, automation, and higher enrichment factors [6]. MOFs are a kind of porous three-dimension materials with the advantages of high porosity and structural diversity. It is widely used in gas storage [7], catalysis [8], separation [9], drug delivery [10], chemical sensing [11,12], supercapacitors [13,14], bio-medical imaging [15]. Due to the above advantages, as adsorbents for SPE, MOFs has gained widely attention.

Here, a method for the analysis of PAHs by SPE-HPLC was built, while lanthanum-terephthalic acid and lanthanum-trimesic acid as mixed adsorbents of SPE.

2 Experimental

2.1. Instrument

LC7011 binary pump and LC7020 UV/Vis detector (Hanon, China) were used for the high performance liquid chromatographic separation. ACCULAB analytical balance (Tianchuang, China) was employed to accurately weight PAHs standards.

2.2. Chemicals and reagents

The chemicals and reagents used are at least analytically grade. Lanthanum nitrate hexahydrate, methanol, dichloromethane and acetone were purchased from Tianjin Kemiu Chemical Co., Ltd (Tianjin, China). Terephthalic acid, trimesic acid, naphthalene, acenaphthylene, acenaphthene, phenanthrene, anthracene, fluoranthene, and pyrene were purchased from Shanghai Dibai Chemical Technology co., Ltd (Shanghai, China). A mixed solution of seven PAHs of 200 mg/L was prepared as a stock solution. PAHs water sample was prepared by diluting the stock solution.

2.3. The preparation of MOFs

4.505 g lanthanum nitrate hexahydrate and 0.864 g terephthalic acid, which weighted by analytical balance were mixed and dissolved in 15 mL of high-purity water.
in a 25 beaker to prepare lanthanum-terephthalic acid MOFs. After magnetic stirring for 20 min, the obtained substance was poured into a 40 mL Teflon-lined stainless autoclaves and maintained at 220°C for 72 h. Then, the substance was washed with high-purity water and collected by filter paper. At last, the prepared MOFs was dried at 120°C for 12 h. The process of preparation of lanthanum-trimesic acid is same to the previous one, except that 1.050 g lanthanum nitrate hexahydrate and 2.165 g trimesic acid were used as reaction reagents.

3 Results and discussion

3.1. Determination of the proportion and flow rate of the mobile phase

It is well known that the proportion and flow rate of the mobile phase have a great effect on the separation of the liquid chromatography. In this work, the effect of acetonitrile proportion in the mobile phase varied from 55% to 85% and the flow rate changed 0.8 mL/min to 1.2 mL/min on separation of PAHs were studied while acetonitrile-water as mobile phase. In Figure 1, it can be seen that with the acetonitrile proportion in mobile phase changed from 55% to 75%, the resolution of seven PAHs were gradually increased, and the baseline separation was achieved when the acetonitrile proportion was 75%. When the acetonitrile proportion in mobile phase was further increased, the resolutions of PAHs decreased. Therefore, 75% acetonitrile was chosen for subsequent experiments. 1.0 mL/min flow rate was chosen as the compromise between retention time and peak area.

3.2. Effect of water sample volume on PAHs enrichment

In order to obtain the optimal volume of water sample, the effect of water sample volume on PAHs enrichment was studied. In Figure 3, it can be seen that while water sample volume varying from 250 mL to 500 mL, the peak area of all seven PAHs had little change. However, while water sample volume varying from 500 mL to 750 mL, the peak area increased significantly, exceeding 750 mL, the peak area remained basically unchanged. Although the larger of the water sample amount, the larger of the peak area, however, the extraction time will be longer. Therefore, it was 750 mL that used as the optimal water sample volume.

![Figure 2. The different mobile rate](image2)

![Figure 3. Effect of water sample amount on PAHs enrichment](image3)

![Figure 4. Effect of adsorbent mass on PAHs enrichment](image4)
3.4. Effect of pH on PAHs enrichment

The effect of water samples with different pH values on the enrichment of PAHs was examined. The experimental results are shown in Figure 5. With the pH of water sample increasing from 2.0 to 7.0, the peak area increased. After that, peak area decreased. Therefore, a neutral water sample for subsequent experiments was selected.

![Figure 5. Effect of pH on PAHs enrichment](image)

3.5. Effect of methanol elution volume on PAHs enrichment

In order to determine the optimal methanol elution volume, the effect of methanol elution volume on PAHs was discussed. The experimental results are shown in Figure 6. While the amount of methanol increased from 0.4 mL to 0.8 mL, the peak area was gradually increased. Then, the volume of methanol eluted was continuously increased, the peak area was gradually decreased with the elution volume varied from 0.8 mL to 1.2 mL. Therefore, it was 0.8 mL that used as the optimal methanol elution volumes.

3.6. Analytical Figures of Merit

Different concentrations of PAHs water samples were prepared. Under the optimal conditions (750 mL neutral water sample, 8 mg adsorbent mass, and 0.8 mL methanol elution volume) PAHs in water samples were detected by SPE-HPLC. The experimental results are shown in Table 1.

| Analyte     | Linear equation | Correlation coefficient | Recovery rate (%) |
|-------------|-----------------|-------------------------|-------------------|
| naphthalene | y=278.5x-8.6743 | 0.999                   | 80.67             |
|acenaphthylene| y=302.39x+0.8013 | 0.991                   | 80.06             |
|acenaphthene | y=663.98x-12.613| 0.9601                  | 54.69             |
|phenanthrene | y=85375x-2160.5 | 0.976                   | 82.62             |
|anthracene  | y=226254x-2233.9| 0.9817                  | 118.87            |
|fluoranthene | y=49088x-850.01 | 0.9581                  | 70.30             |
|pyrene      | y=41558x-855.22 | 0.9776                  | 95.57             |

4 Conclusion

In summary, a method for the detected of trace PAHs in environmental samples by a mixed adsorbent of lanthanum-terephthalic acid and lanthanum-trimesic acid for SPE combined with HPLC was developed. The experimental results showed that the feasibility of using lanthanum-terephthalic acid and lanthanum-trimesic acid as composite adsorbents for the enrichment of trace PAHs in environmental sample.
