A Better Variant of Self-Critical Sequence Training

Ruotian Luo

rluo@ttic.edu

Abstract
In this work, we present a simple yet better variant of Self-Critical Sequence Training. We make a simple change in the choice of baseline function in REINFORCE algorithm. The new baseline can bring better performance with no extra cost, compared to the greedy decoding baseline.

1 Introduction
Self-Critical Sequence Training (SCST), upon its release, has been a popular way to train sequence generation models. While originally proposed for image captioning task, SCST not only has become the new standard for training captioning models (Yao et al., 2017; Dognin et al., 2019; Luo et al., 2018; Jiang et al., 2018; Liu et al., 2018b; Ling and Fidler, 2017; Liu et al., 2018a; Chen et al., 2019; Yang et al., 2019; Zhao et al., 2018), but also has been applied to many other tasks, like video captioning (Li et al., 2018; Chen et al., 2018; Li and Gong, 2019), reading comprehension (Hu et al., 2017), summarization (Celikyilmaz et al., 2018; Paulus et al., 2017; Wang et al., 2018; Pasunuru and Bansal, 2018), image paragraph generation (Melas-Kyriazi et al., 2018), speech recognition (Zhou et al., 2018).

SCST is used to optimize generated sequences over a non-differentiable objective, usually the evaluation metrics, for example, CIDER for captioning, ROUGE for summarization. To optimize such objective, SCST adopts REINFORCE with baseline (Williams, 1992), where a “Self-Critical” baseline is used; specifically, the score of the greedy decoding output is used as the baseline. This is proved to be better than learned baseline function which is more commonly used in Reinforcement Learning literature.

In this work, we present a different baseline choice which was first proposed in (Mnih and Rezende, 2016), to the best of our knowledge. With more elaboration in Sec. 3, this baseline can be described as a variant of “Self-Critical”. This method is simple, but also faster and more effective compared to the greedy decoding baseline used in SCST.

2 Recap for SCST
MIXER (Ranzato et al., 2015) is the first to use REINFORCE algorithm for sequence generation training. They use a learned function approximator to get the baseline.

SCST inherits the REINFORCE algorithm from MIXER, but discards the learned baseline function. Instead, SCST uses the reward of the greedy decoding result as the baseline, achieving better captioning performance and lower gradient variance.

2.1 Math formulation
The goal of SCST, for example in captioning, is to maximize the expected CIDEr score of generated captions.

$$\max_\theta E_\hat{c} \sim p_\theta(c|I)[R(\hat{c})]$$

where $\hat{c}$ is a sampled caption; $I$ is the image; $p_\theta(c|I)$ is the captioning model parameterized by $\theta$, and $R(\cdot)$ is the CIDEr score.

Since this objective is not non-differentiable with respect to $\theta$, back propagation is not feasible. To optimize it, a policy gradient method, specifically REINFORCE with baseline (Williams, 1992) is used.

$$\nabla_\theta E[R] \approx (R(\hat{c}) - b)\nabla_\theta \log p_\theta(\hat{c}|I)$$

The policy gradient method allows estimating the gradient from individual samples (the right-hand side) and applying gradient ascent. To reduce the variance of the estimation, a baseline $b$ is needed, and $b$ has to be independent of $\hat{c}$. 
In SCST, the baseline is set to be the CIDEr score of the greedy decoding caption, denoted as $c^\ast$. Thus, we have

$$\nabla_\theta E[R] \approx (R(\hat{c}) - R(c^\ast)) \nabla_\theta \log p_\theta(\hat{c}|I)$$

### 3 The Better SCST

The success of SCST comes from better gradient variance reduction introduced by the greedy decoding baseline. In our variant, we use the baseline proposed in (Mnih and Rezende, 2016) to achieve even better variance reduction.

Following (Mnih and Rezende, 2016), we sample $K$ captions for each image when applying REINFORCE: $\hat{c}_1, \ldots, \hat{c}_K, \hat{c}_k \sim p_\theta(c|I)$.

The baseline for each sampled caption is defined as the average reward of the rest samples. That is, for caption $\hat{c}_k$, its baseline is

$$b_k = \frac{1}{K-1} \sum_{j \neq k} R(\hat{c}_j)$$

(1)

Since each sample is independently drawn, $b_k$ is a valid baseline. The final gradient estimation is

$$\nabla_\theta \approx \left( R(\hat{c}_k) - \frac{1}{K-1} \sum_{j \neq k} R(\hat{c}_j) \right) \nabla_\theta \log p_\theta(\hat{c}_k|I)$$

(2)

Note that, $b_k$ is an estimation of expected reward, which is similar to the learning objective of value functions in other Reinforcement Learning algorithms. The expected reward is usually a good baseline choice in that it can effectively reduce gradient variance. In Sec. 4, we show that our gradient variance is lower than SCST empirically.

It is still a “Self-Critical” baseline because the critic is still from itself: its other sampling results, instead of the greedy decoding result.

### 4 Experiments

For all models, we first pretrain them using standard cross-entropy loss and then switch to Self-Critical training.

For a fair comparison, during Self-Critical stage, we always sample 5 captions for each image, same for both SCST and our variant.

All the experiments are done on COCO captioning dataset (Lin et al., 2014). The scores are obtained on Karpathy test split (Karpathy and Fei-Fei, 2015) with beam search of beam size 5 if not explicitly noted.

### Speed

Since no extra greedy decoding is needed, our method is slightly faster than SCST.

### Performance on different model architectures

We experiment with four different architectures. FC and Att2in are from SCST (Rennie et al., 2017), UpDown is from (Anderson et al., 2018). Transformer is adapted from (Vaswani et al., 2017) for captioning task.

Table 1 shows that our variant is better than SCST on all architectures, especially on Transformer.

### Different training hyperparameters

Here we adopt a different training setting (‘Long’) for UpDown model. The ‘Long’ setting (from https://github.com/yangxuntu/SGAE) uses a larger batch size and a longer training time. Table 2 shows that there is always a gap between our method and SCST which cannot be closed by longer training or a larger batch size.

### Multiple runs

Table 3 shows that our variant is consistently better than SCST with different random seeds. All the models use ‘Long’ setting with UpDown model.

Specifically, we pretrain 5 models using cross-entropy loss, and then apply SCST and our method respectively. The same $RS\ast$ means they share the same pretrained model.

### Training curves

Figure 1 shows the model performance on the validation set during training, after entering Self-Critical stage. The scores are averaged over the 5 UpDown(Long) models above.

### Is greedy decoding necessary for SCST

We also experiment with a variant of SCST, by replacing the greedy decoding output with a sampled output. (This is similar to our method with $K = 2$.) Table 4 shows that one sample baseline is worse than greedy decoding. This is as expected, because using one sample to estimate the expected reward is too noisy, resulting in larger gradient variance, while the reward of greedy decoding output may be biased but more stable. It also shows that it is important to use sufficiently large $K$ to have a better estimation of expected reward.

### Variance reduction

As stated in Sec. 3, the motivation of using the average reward baseline is for better variance reduction. Here we show it indeed is better in practice.

The gradient variance is calculated as follows. At the end of each epoch, we take the saved model
| FC(SCST)     | 74.7 | 57.8 | 43.0 | 31.7 | 54.0 | 25.2 | 104.5 | 18.4 |
|-------------|------|------|------|------|------|------|-------|------|
| FC(Ours)    | 75.4 | 57.9 | 43.0 | 31.6 | 54.1 | 25.4 | 105.3 | 18.6 |
| Att2in(SCST)| 78.0 | 61.8 | 47.0 | 35.3 | 56.7 | 27.1 | 117.4 | 20.5 |
| Att2in(Ours)| 78.4 | 62.1 | 47.3 | 35.6 | 56.9 | 27.3 | 119.5 | 20.7 |
| UpDown(SCST)| 79.4 | 63.3 | 48.6 | 36.7 | 57.6 | 27.9 | 122.7 | 21.5 |
| UpDown(Ours)| 80.0 | 63.9 | 49.1 | 37.2 | 57.8 | 28.0 | 123.9 | 21.5 |
| Transformer(SCST) | 80.0 | 64.6 | 50.3 | 38.6 | 58.4 | 28.6 | 126.6 | 22.2 |
| Transformer(Ours) | 80.7 | 65.6 | 51.3 | 39.4 | 58.7 | 28.9 | 129.6 | 22.8 |

Table 1: The performance of our method on different model architectures. The numbers are from authors’ own implementation.

| UpDown+SCST | 79.4 | 63.3 | 48.6 | 36.7 | 57.6 | 27.9 | 122.7 | 21.5 |
|-------------|------|------|------|------|------|------|-------|------|
| UpDown+Ours | 80.0 | 63.9 | 49.1 | 37.2 | 57.8 | 28.0 | 123.9 | 21.5 |
| UpDown(Long)+SCST | 80.3 | 64.5 | 49.9 | 38.0 | 58.3 | 28.4 | 127.2 | 21.9 |
| UpDown(Long)+Ours | 80.4 | 64.7 | 50.1 | 38.1 | 58.4 | 28.5 | 127.9 | 22.0 |

Table 2: The performance of UpDown model with SCST/Ours under two different hyperparameter settings.

| RS1+SCST | 80.3 | 64.5 | 49.9 | 38.0 | 58.3 | 28.4 | 127.2 | 21.9 |
|-----------|------|------|------|------|------|------|-------|------|
| RS1+Ours | 80.4 | 64.7 | 50.1 | 38.1 | 58.4 | 28.5 | 127.9 | 22.0 |
| RS2+SCST | 80.2 | 64.5 | 49.9 | 37.9 | 58.3 | 28.3 | 127.2 | 21.9 |
| RS2+Ours | 80.2 | 64.5 | 50.0 | 38.1 | 58.2 | 28.4 | 128.0 | 22.0 |
| RS3+SCST | 80.2 | 64.5 | 50.0 | 38.1 | 58.3 | 28.3 | 127.3 | 21.8 |
| RS3+Ours | 80.2 | 64.5 | 50.0 | 38.1 | 58.3 | 28.4 | 127.9 | 22.0 |
| RS4+SCST | 80.2 | 64.5 | 49.9 | 37.9 | 58.2 | 28.3 | 127.0 | 21.8 |
| RS4+Ours | 80.2 | 64.5 | 50.0 | 38.0 | 58.3 | 28.5 | 127.7 | 22.0 |
| RS5+SCST | 80.2 | 64.6 | 50.2 | 38.4 | 58.4 | 28.5 | 127.6 | 21.9 |
| RS5+Ours | 80.2 | 64.5 | 49.8 | 37.9 | 58.3 | 28.4 | 127.8 | 22.0 |
| Mean(SCST) | 80.2 | 64.5 | 50.0 | 38.0 | 58.3 | 28.4 | 127.5 | 21.8 |
| Mean(Ours) | 80.2 | 64.6 | 50.0 | 38.1 | 58.3 | 28.4 | 127.9 | 22.0 |

Table 3: Within the first 5 block, the models share the same cross-entropy pretrained model (RS stands for random seed). The last block shows the average score of 5 models.

| UpDown(SCST) | 79.4 | 63.3 | 48.6 | 36.7 | 57.6 | 27.9 | 122.7 | 21.5 |
|--------------|------|------|------|------|------|------|-------|------|
| UpDown(Sample) | 79.6 | 63.5 | 48.7 | 36.7 | 57.7 | 27.8 | 122.1 | 21.3 |

Table 4: Replacing the greedy decoding output \( c^* \) in SCST with a separately drawn sample \( \bar{c}' \).
and run through the training set. We get the gradients from each training batch and calculate the variance for each parameter gradient across batches. To get a single value, we take the average of all the parameters. A mathematic expression of this process is:

\[ V = \text{Mean}_i \left[ \text{Var}_b[\text{grad}^b_{\theta_i}] \right] \]

where \( i \) is the index of each parameter; \( b \) is the index of each batch; \( \theta_i \) is the network parameters; \( \text{grad}^b_{\theta_i} \) is the gradient of \( \theta_i \) at batch \( b \).

As shown in Fig. 2, our method is always getting lower variance than SCST.

5 Code release

Code has been released at https://github.com/ruotianluo/self-critical.pytorch. More instructions of using this method are at https://github.com/ruotianluo/self-critical.pytorch/tree/master/projects/NewSelfCritical

6 Conclusion

We propose a variant of popular SCST, which can work as a drop-in replacement for SCST. This variant reduces the gradient variance when applying REINFORCE by modifying the baseline function. We show that this method is effective on Image Captioning task, and we believe it should benefit other tasks as well.
