Abstract

Using a probabilistic approach we study the parallel dynamics of fully connected $Q$-Ising neural networks for arbitrary $Q$. A Lyapunov function is shown to exist at zero temperature. A recursive scheme is set up to determine the time evolution of the order parameters through the evolution of the distribution of the local field. As an illustrative example, an explicit analysis is carried out for the first three time steps. For the case of the $Q = 3$ model these theoretical results are compared with extensive numerical simulations. Finally, equilibrium fixed-point equations are derived and compared with the thermodynamic approach based upon the replica-symmetric mean-field approximation.

Key words: Fully-connected networks; $Q$-Ising neurons; parallel dynamics; probabilistic approach

1 Introduction

The parallel dynamics of extremely diluted asymmetric and layered feed-forward $Q \geq 2$-Ising neural networks have been solved exactly (cfr. [1]-[4] and the references cited therein). This has been possible because in these types of networks one knows that there are no feedback loops as time progresses. In particular, this allows one to derive recursion relations for the relevant order parameters of these systems: the main overlap for the condensed pattern, the mean of the neuron activities and the variance of the residual overlap responsible for the intrinsic noise in the dynamics of the main overlap (sometimes called the width-parameter).

These results are in strong contrast to those for the parallel dynamics of networks with symmetric connections. For these systems it turns out that even in the diluted $Q = 2$ case, feedback correlations become essential from the second time step onwards, which already complicates the dynamics in a nontrivial way [5]-[6]. For fully connected $Q = 2$ systems, an increasing complexity of such long-term temporal correlations makes the dynamics, in general, extremely complicated. Therefore, either approximate treatments of the feedback influence on the network evolution or only the first few time steps of the main overlap evolution have been analyzed so far. Nevertheless, this has led to some important insights into the dynamics of the Little-Hopfield model (cfr. [7]-[15] and references therein).

In this paper we consider the zero-temperature parallel dynamics of fully connected $Q$-Ising neural networks for general $Q$. Generalizing a $Q = 2$ result from the literature [16]-[17] we find that there exists a Lyapunov function leading to the occurrence of fixed-points and two-cycles. Since two-cycles in the $Q = 2$ Little-Hopfield model seem to appear far from the retrieval region [18] and/or seem to involve only a tiny fraction of all spins [19], we only look at the fixed-point dynamics.

Using a probabilistic approach [13] we extend our analysis for extremely diluted [2],[20] and layered $Q$-Ising networks [4] to the non-trivial case of fully connected systems at zero temperature. In particular, we develop a recursive scheme to calculate the relevant order parameters of the system, i.e., the main overlap, the activity and the variance of the residual overlap, for any time step. We write out these expressions in detail for the first three time steps of the dynamics. Furthermore, under the condition that the local field becomes stationary we derive the fixed-point equations for these order parameters. They are found to be the same as those derived via
thermodynamical methods [21]. Finally, extensive numerical simulations for the \( Q = 3 \) model are compared with the theoretical results.

The rest of the paper is organized as follows. In Section 2 we introduce the model, its dynamics and the Hamming distance as a macroscopic measure for the retrieval quality. In Section 3 we use the probabilistic approach in order to derive a recursive scheme for the evolution of the distribution of the local field, leading to recursion relations for the order parameters of the model. Using this general scheme, we explicitly calculate in Section 4 the order parameters for the first three time steps of the dynamics. In Section 5 we show the existence of a Lyapunov function at zero temperature and we discuss the evolution of the system to fixed-point attractors. A detailed discussion of the theoretical results obtained in Section 4 and a comparison with extensive numerical simulations are presented in Section 6. Some concluding remarks are given in Section 7.

2 The model

Consider a neural network \( \Lambda \) consisting of \( N \) neurons which can take values \( \sigma_j \) from a discrete set \( S = \{-1 = s_1 < s_2 < \ldots < s_Q = +1\} \). Given the configuration \( \sigma_\Lambda(t) \equiv \{\sigma_j(t)\}, j \in \Lambda = \{1, \ldots, N\} \), the local field in neuron \( i \) equals

\[
h_i(\sigma_\Lambda \setminus \{i\})(t) = \sum_{j \in \Lambda \setminus \{i\}} J_{ij}\sigma_j(t), \tag{1}
\]

with \( J_{ij} \) the synaptic couplings between neurons \( i \) and \( j \). In the sequel we write the shorthand notation \( h_{\Lambda,i}(t) \equiv h_i(\sigma_\Lambda \setminus \{i\})(t) \). The configuration \( \sigma_\Lambda(t = 0) \) is chosen as input. At zero temperature all neurons are updated in parallel according to the rule

\[
\sigma_i(t) \rightarrow \sigma_i(t + 1) = s_k : \min_{s \in S} \epsilon_i[s|\sigma_\Lambda \setminus \{i\}](t)] = \epsilon_i[s_k|\sigma_\Lambda \setminus \{i\}](t)]. \tag{2}
\]

Here the energy potential \( \epsilon_i[s|\sigma_\Lambda \setminus \{i\}] \) is defined by

\[
\epsilon_i[s|\sigma_\Lambda \setminus \{i\}] = -\frac{1}{2}[h_i(\sigma_\Lambda \setminus \{i\})s - bs^2], \tag{3}
\]

where \( b > 0 \) is the gain parameter of the system. The updating rule (2) is equivalent to using a gain function \( g_b(\cdot) \),

\[
\sigma_i(t + 1) = g_b(h_{\Lambda,i}(t))
\]
\[ g_b(x) \equiv \sum_{k=1}^{Q} s_k [\theta (b(s_{k+1} + s_k) - x) - \theta (b(s_k + s_{k-1}) - x)] \] (4)

with \( s_0 \equiv -\infty \) and \( s_{Q+1} \equiv +\infty \). For finite \( Q \), this gain function \( g_b(\cdot) \) is a step function. The gain parameter \( b \) controls the average slope of \( g_b(\cdot) \).

In this network we want to store \( p = \alpha N \) patterns. These patterns are a collection of independent and identically distributed random variables (i.i.d.r.v.), \( \{\xi^\mu_i \in S\} \), \( \mu \in \mathcal{P} = \{1, \ldots, p\} \) and \( i \in \Lambda \) with zero mean and variance \( A = \text{Var}[\xi^\mu_i] \). The synaptic couplings between the neurons are chosen according to the Hebb learning rule

\[ J_{ij} = \frac{1}{N A} \sum_{\mu \in \mathcal{P}} \xi^\mu_i \xi^\mu_j \quad \text{for} \quad i \neq j, \quad J_{ii} = 0. \] (5)

To measure the retrieval quality of the system one can use the Hamming distance between a stored pattern and the microscopic state of the network

\[ d(\xi^\mu, \sigma_\Lambda(t)) = \frac{1}{N} \sum_{i \in \Lambda} |\xi^\mu_i - \sigma_i(t)|^2. \] (6)

This naturally introduces the main overlap

\[ m^\mu_\Lambda(t) = \frac{1}{N A} \sum_{i \in \Lambda} \xi^\mu_i \sigma_i(t) \quad \mu \in \mathcal{P} \] (7)

and the arithmetic mean of the neuron activities

\[ a_\Lambda(t) = \frac{1}{N} \sum_{i \in \Lambda} |\sigma_i(t)|^2. \] (8)

### 3 General dynamical scheme

It is known that contrary to the asymmetrically diluted and layered neural networks, the parallel dynamics of fully connected systems, even at zero temperature, is not exactly solvable because of the strong feedback correlations [22].

On the basis of the probabilistic approach used before (see, e.g., [4], [13]) we develop in this section a recursive dynamical scheme in order to calculate the distribution of the local field at a general time step, for \( Q \geq 2 \)-Ising neural
networks. This results in recursion relations determining the evolution of the order parameters of these systems.

Suppose that the initial configuration of the network \( \{ \sigma_i(0) \}, i \in \Lambda \), is a collection of i.i.d.r.v. with mean \( E[\sigma_i(0)] = 0 \), variance \( \text{Var}[\sigma_i(0)] = a_0 \), and correlated with only one stored pattern, say the first one \( \{ \xi_1^\mu \} \):

\[
E[\xi_1^\mu \sigma_i(0)] = \delta_{\mu,1} m_0^1 A \quad m_0^1 > 0.
\]  

This implies that by the law of large numbers (LLN) one gets for the main overlap and the activity at \( t = 0 \)

\[
m^1(0) \equiv \lim_{N \to \infty} m^1_{\Lambda}(0) \overset{P_r}{=} \frac{1}{A} E[\xi_1^i \sigma_i(0)] = m_0^1 \quad (10)
\]

\[
a(0) \equiv \lim_{N \to \infty} a_{\Lambda}(0) \overset{P_r}{=} E[\sigma_i^2(0)] = a_0 \quad (11)
\]

where the convergence is in probability \( [23] \). Using standard signal-to-noise techniques (see, e.g., \( [20] \)), we find the local field at \( t = 0 \)

\[
h_i(0) = \lim_{N \to \infty} \left[ \xi_1^i m_{\Lambda \setminus \{i\}}^1(0) + \frac{1}{NA} \sum_{\mu \in \mathcal{P} \setminus \{1\}} \sum_{j \in \Lambda \setminus \{i\}} \xi_1^\mu \xi_1^\mu \sigma_j(0) \right]
\]

\[
\overset{D}{=} \xi_1^i m^1(0) + \mathcal{N}(0, \alpha a_0), \quad (12)
\]

where the convergence is in distribution (see, e.g., \( [23] \)). The quantity \( \mathcal{N}(0, d) \) represents a Gaussian random variable with mean 0 and variance \( d \).

For a general time step we find from eq. (4) and the LLN in the limit \( N \to \infty \) for the main overlap (7) and the activity (8)

\[
m^1(t+1) \overset{P_r}{=} \frac{1}{A} \langle \langle \xi_1^i g_b(h_i(t)) \rangle \rangle \quad (13)
\]

\[
a(t+1) \overset{P_r}{=} \langle \langle g^2_b(h_i(t)) \rangle \rangle \quad (14)
\]

with \( h_i(t) \equiv \lim_{N \to \infty} h_{\Lambda,i}(t) \). In the above \( \langle \langle \cdot \rangle \rangle \) denotes the average both over the distribution of the embedded patterns \( \{ \xi_1^\mu \} \) and the initial configurations \( \{ \sigma_i(0) \} \). The average over the initial configurations is hidden in an average over the local field through the updating rule (4). From the study of layered networks \( [3] - [4] \) we know already that due to the correlations there will be a third important parameter in the description of the time evolution of the
system: the influence of the non-condensed patterns which is expressed by the variance of the residual overlaps

\[ D(t) \equiv \text{Var}[r^\mu(t)] \]  
\[ r^\mu(t) \equiv \lim_{N \to \infty} r^\mu_{\Lambda}(t) = \lim_{N \to \infty} \frac{1}{\sqrt{N}} \sum_{i \in \Lambda} \xi^\mu_i \sigma_i(t) \quad \mu \in \mathcal{P} \setminus \{1\}. \]  

Clearly, \( D(0) = a_0/A \). The distribution of the embedded patterns is given. It is the purpose of this section to calculate the distribution of the local field as a function of time.

We start by rewriting the local field (1) at time \( t \) in the following way

\[ h_{\Lambda,i}(t) = \xi^1_i m^1_{\Lambda}(t) + \frac{1}{N A} \sum_{j \in \Lambda} \sum_{\mu \in \mathcal{P}} \xi^\mu_i \xi^\mu_j \sigma_j(t) - \alpha \sigma_i(t) \]

\[ = \xi^1_i m^1_{\Lambda}(t) - \alpha \sigma_i(t) + \frac{1}{\sqrt{N}} \sum_{\mu \in \mathcal{P} \setminus \{1\}} \xi^\mu_i r^\mu_{\Lambda}(t). \]

From a technical point of view the explicit addition and subtraction of the \( \alpha \sigma_i(t) \) term in (17) is convenient in order to treat all indices in the sum over \( j \) on an equal footing. This turns out to be important to take into account all possible feedback loops.

We would like to remark that the set of \( \alpha N \) variables \( \{\xi^\mu_i r^\mu_{\Lambda}(t)\}_\mu \) appearing in the last term of (18) are not independent because the \( \xi^\mu_i \) are weakly dependent on the \( r^\nu_{\Lambda}(t) \), \( \nu \neq \mu \). On the contrary, in the case of layered or diluted networks all terms of this set of variables are independent such that their sum is a normal distribution. Moreover, \( r^\mu_{\Lambda \setminus \{i\}}(t) \) and \( \xi^\mu_i \) are also independent implying that the mean and the variance of this distribution are known directly. The same is true for the fully connected model at time \( t = 0 \) where the network states \( \{\sigma_i(0)\}_i \) are randomly distributed and independent of the non-condensed (\( \mu > 1 \)) embedded patterns. But after applying the dynamics the \( \sigma_i(t) \) and the \( \xi^\mu_i \) become dependent, leading to a weak dependence of \( r^\mu_{\Lambda \setminus \{i\}}(t) \) and \( \xi^\mu_i \). This microscopic dependence gives rise to a macroscopic contribution after summing and taking the limit \( N \to \infty \). In this respect we mention that in ref. [9] an approximation has been put forward by neglecting precisely these correlations between the \( \xi^\mu_i \) and the \( r^\mu_{\Lambda \setminus \{i\}}(t) \). For an overview of improvements of this approximation for \( Q = 2 \) and corresponding numerical simulations we refer to [15].

In order to determine the structure of the local field for fully connected networks, we first concentrate on the evolution of the residual overlap \( r^\mu_{\Lambda}(t), \mu \in \)
\[ P \setminus \{ 1 \} \]. As mentioned above the dynamics induces the dependence of \( \{ \sigma_i(t) \} \) and \( \{ \xi_i^\mu \} \). To study its consequences we rewrite the residual overlap (16) as

\[
r^\mu_\Lambda(t + 1) = \frac{1}{\sqrt{NA}} \sum_{i \in \Lambda} \xi_i^\mu g_b(\hat{h}^\mu_{\Lambda,i}(t)) + \frac{1}{\sqrt{N}} \xi_i^\mu r^\mu_\Lambda(t)
\]  

with

\[
\hat{h}^\mu_{\Lambda,i}(t) = h_{\Lambda,i}(t) - \frac{1}{\sqrt{N}} \xi_i^\mu r^\mu_\Lambda(t).
\]

By subtracting the term \( \xi_i^\mu r^\mu_\Lambda(t)/\sqrt{N} \) the modified local field \( \hat{h}^\mu_{\Lambda,i}(t) \) becomes only weakly dependent on \( \xi_i^\mu \), whereas \( h_{\Lambda,i}(t) \) depends strongly on \( \xi_i^\mu \). The gain function \( g_b(\cdot) \) is a step function that changes its value by \( s_k + 1 - s_k \) at \( b(s_k + s_{k+1}), k = 1, \ldots, Q - 1 \). Hence the term \( \xi_i^\mu r^\mu_\Lambda(t)/\sqrt{N} \) in (19) becomes relevant if for some \( k \)

\[
|\hat{h}^\mu_{\Lambda,i}(t) - b(s_k + s_{k+1})| < \frac{|\xi_i^\mu r^\mu_\Lambda(t)|}{\sqrt{N}} \quad k = 1, \ldots, Q - 1.
\]

Denoting by \( I_k \) the set of indices satisfying condition (21), we split the residual overlap into two sums:

\[
r^\mu_\Lambda(t + 1) = \frac{1}{\sqrt{NA}} \sum_{i \notin \cup_k I_k} \xi_i^\mu g_b(\hat{h}^\mu_{\Lambda,i}(t)) + \frac{1}{\sqrt{NA}} \sum_{k=1}^{Q-1} \sum_{i \in I_k} \xi_i^\mu \left\{ g_b(\hat{h}^\mu_{\Lambda,i}(t)) + \frac{1}{2} \left[ \text{sign}(b(s_k + s_{k+1}) - \hat{h}^\mu_{\Lambda,i}(t)) + \text{sign}(\frac{1}{\sqrt{N}} \xi_i^\mu r^\mu_\Lambda(t)) \right] (s_{k+1} - s_k) \right\}.
\]

In the argument of \( g_b(\cdot) \) in the first term of (22) the term \( \xi_i^\mu r^\mu_\Lambda(t)/\sqrt{N} \) is left out since it can not change the value of \( g_b(\cdot) \) by definition of the sets \( I_k \). Combining the first two terms, eq. (22) can be rewritten as

\[
r^\mu_\Lambda(t + 1) = \frac{1}{\sqrt{NA}} \sum_{i \in \Lambda} \xi_i^\mu g_b(\hat{h}^\mu_{\Lambda,i}(t)) + \frac{1}{\sqrt{NA}} \sum_{k=1}^{Q-1} \sum_{i \in I_k} \xi_i^\mu \left[ \text{sign}(b(s_k + s_{k+1}) - \hat{h}^\mu_{\Lambda,i}(t)) + \text{sign}(\frac{1}{\sqrt{N}} \xi_i^\mu r^\mu_\Lambda(t)) \right] (s_{k+1} - s_k).
\]
We then consider the limit $N \to \infty$. In this limit the cardinal number of the set $I_k$ becomes deterministic

$$\lim_{N \to \infty} \frac{|I_k|}{\sqrt{N}} = 2|\xi^\mu r^\mu(t)|f_{\hat{h}^\mu(t)}(b(s_{k+1} + s_k))$$

(24)

with $f_{\hat{h}^\mu(t)}$ the probability density of the modified local field $\hat{h}^\mu_i(t)$ at time $t$. We remark that in the thermodynamic limit the density distribution of the modified local field $\hat{h}^\mu_i(t)$ at time $t$ equals the density distribution of the local field $h_i(t)$ itself.

Furthermore, we apply the CLT on the first term of (23) and the LLN on the second term with the random variable $r^\mu(t)$ fixed. This yields the following result

$$r^\mu(t + 1) = \tilde{r}^\mu(t) + \chi(t)r^\mu(t)$$

(25)

where, recalling eqs. [14] and [20]

$$\tilde{r}^\mu(t) \equiv \lim_{N \to \infty} \frac{1}{A\sqrt{N}} \sum_{i \in \Lambda} \xi^\mu g_b(\hat{h}^\mu_{\Lambda, i}(t)) \overset{D}{=} \mathcal{N}_\mu(0, a(t + 1)/A)$$

(26)

because of the weak dependence of $\hat{h}^\mu_i(t)$ and $\xi^\mu_i$, and

$$\chi(t) = \sum_{k=1}^{Q-1} f_{\hat{h}^\mu_i(t)}(b(s_{k+1} + s_k)) (s_{k+1} - s_k).$$

(27)

From the relation (25) one finds a recursion relation for the variance of the residual overlap

$$D(t + 1) = \frac{a(t + 1)}{A} + \chi^2(t)D(t) + 2\chi(t)\text{Cov}[\tilde{r}^\mu(t), r^\mu(t)].$$

(28)

At this point it is interesting to remark that the last term on the r.h.s. of (28) is entirely coming from the correlations caused by the fully connected structure of the network. It is absent for layered (compare eq. (30c) of ref. [4]) and hence, of course, also for extremely diluted asymmetric architectures. In the latter case also the second term on the r.h.s. of (28) disappears.

Starting from the local field at time $t+1$ in the form of eq. (18) and using expressions (29), (26) and (27) we obtain in the limit $N \to \infty$, after some straightforward manipulations

$$h_i(t+1) = \xi^1 i^1 m^1(t+1) + \chi(t)[h_i(t) - \xi^1 i^1 m^1(t) + \alpha \sigma_i(t)] + \mathcal{N}(0, \alpha a(t + 1)).$$

(29)
From this it is clear that the local field at time $t + 1$ consists out of a discrete part and a normally distributed part, viz.

$$h_i(t) = M_i(t) + \mathcal{N}(0, V(t))$$  \hspace{1cm} (30)

where $M_i(t)$ satisfies the recursion relation

$$M_i(t + 1) = \chi(t)[M_i(t) - \xi^1_i m^1(t) + \alpha \sigma_i(t)] + \xi^1_i m^1(t + 1)$$  \hspace{1cm} (31)

and

$$V(t + 1) = \alpha AD(t + 1)$$  \hspace{1cm} (32)

with $D(t + 1)$ given by the recursion relation (28).

We still have to determine $f_{h_i(t)}$ in eq. (27). We know that the quantity $M_i(t)$ consists out of the signal term and a discrete noise term, viz.

$$M_i(t) = \xi^1_i m^1(t) + \sum_{t' = 0}^{t-1} \alpha \left[ \prod_{s = t'}^{t-1} \chi(s) \right] \sigma_i(t').$$  \hspace{1cm} (33)

The evolution equation tells us that $\sigma_i(t')$ can be replaced by $g_{h_i(t' - 1)}$ such that the second term of $M_i(t)$ is the sum of stepfunctions of correlated variables. These are also correlated through the dynamics with the normally distributed part of $h_i(t)$. Therefore the local field can be considered as a transformation of a set of correlated normally distributed variables $x_s$, $s = 0, \ldots, t - 2, t$. Defining the correlation matrix $C_{ss'} \equiv \mathbb{E}[x_s x_{s'}]$ we arrive at the following expression for the probability density of the local field at time $t$

$$f_{h_i(t)}(y) = \int \prod_{s=0}^{t-2} dx_s dx_t \, \delta \left( y - M_i(t) - \sqrt{V(t)} x_t \right)$$

$$\times \, \frac{1}{\sqrt{\det(2\pi C)V(t)}} \exp \left( -\frac{1}{2} x^T C^{-1} x \right)$$  \hspace{1cm} (34)

with $x = (x_0, \ldots, x_{t-2}, x_t)$.

Together with the eqs. (13)-(14) for $m^1(t + 1)$ and $a(t + 1)$ the equations (25)-(28), (31) and (14) form a recursive scheme in order to obtain the order parameters of the system. The practical difficulty which remains is the explicit calculation of the correlations in the network at different time steps as present in eq. (28).
4 Evolution equations up to the third time step

Following the general recursive scheme established in Section 3, evolution equations are derived for the order parameters of a fully connected $Q$-Ising network for the first three time steps, taking into account all correlations. This generalizes and extends the $Q = 2$ results in the literature mentioned in the Introduction.

4.1 First step dynamics

Starting from eqs. (12), (13) and (14) one has immediately

\[ m^1(1) = \frac{1}{A} \left\langle \xi^1 \int \mathcal{D}z \ g_b(\xi^1 m^1(0) + \sqrt{\alpha A D(0)} z) \right\rangle \]  

\[ a(1) = \left\langle \int \mathcal{D}z \ g_b^2(\xi^1 m^1(0) + \sqrt{\alpha A D(0)} z) \right\rangle, \]  

where $\langle \cdot \cdot \cdot \rangle$ now stands for the average taken with respect to the distribution of the first pattern and the initial configuration and $\mathcal{D}z$ denotes a Gaussian measure $\mathcal{D}z = dz \exp(-\frac{1}{2}z^2)/\sqrt{2\pi}$. We recall that $D(0) = a_0/A$. Next, from the initial conditions (9)-(12) and the definition of the modified local field (20) one also knows that $\{\xi_i^\mu(0), g_b(\hat{h}_i^\mu(0))\}_i$ and $\{\xi_i^\mu, \sigma_i(0)\}_i$ become a set of uncorrelated parameters for $\mu \in \mathcal{P} \setminus \{1\}$. Here $\hat{h}_i^\mu(t) \equiv \lim_{N \to \infty} \hat{h}_{\Lambda, i}^\mu(t)$. Therefore

\[ \text{Cov}[\bar{r}^\mu(0), r^\mu(0)] = \mathbb{E}[\sigma_i(0)g_b(\hat{h}_i^\mu(0))]. \]  

Using the recursion relation (28) this leads to

\[ D(1) = \frac{a(1)}{A} + \chi^2(0) D(0) + 2 \frac{\chi(0)}{A} \left\langle \sigma(0) \int \mathcal{D}z \ g_b(\xi^1 m^1(0) + \sqrt{\alpha A D(0)} z) \right\rangle \]

with

\[ \chi(0) = \left\langle \frac{1}{\sqrt{\alpha A D(0)}} \int \mathcal{D}z \ g_b(\xi^1 m^1(0) + \sqrt{\alpha A D(0)} z) \right\rangle. \]

These results generalize the corresponding $Q = 2$ results (see, e.g., [7] and [13]).
4.2 Second step dynamics

First we need the distribution of the local field at time \( t = 1 \). This follows immediately from eqs. (31) and (32)

\[
h_i(1) = \xi_i^1 m_i^1(1) + \chi(0)[h_i(0) - \xi_i^1 m_i^1(0) + \alpha \sigma_i(0)] + \mathcal{N}(0, \alpha a(1)).
\] (40)

Recalling again eqs. (13) and (14), the main overlap and the activity read

\[
m^1(2) = \frac{1}{A} \left\langle \left\langle \xi_1^1 \int Dz \; g_b \left( \xi^1 m^1(1) + \alpha \chi(0) \sigma(0) + \sqrt{\alpha AD(1)} z \right) \right\rangle \right\rangle \] (41)

\[
a(2) = \left\langle \left\langle \int Dz \; g_b^2 \left( \xi^1 m^1(0) + \alpha \chi(0) \sigma(0) + \sqrt{\alpha AD(1)} z \right) \right\rangle \right\rangle \] (42)

and

\[
\chi(1) = \frac{1}{\sqrt{\alpha AD(1)}} \left\langle \left\langle \int Dz \; g_b \left( \xi^1 m^1(1) + \alpha \chi(0) \sigma(0) + \sqrt{\alpha AD(1)} z \right) \right\rangle \right\rangle .
\] (43)

These equations correspond to the equations for the \( Q = 2 \)-network found in [8]. The calculation of the third order parameter, i.e., the variance of the residual overlap, needs some more work. From the recursion formula (25) one finds

\[
\text{Cov}[^\mu(1), r^\mu(1)] = \text{Cov}[^\mu(1), ^\mu(0)] + \chi(0) \text{Cov}[^\mu(1), r^\mu(0)]
\] (44)

with the correlation parameters, \( R(t, \tilde{t}) \), defined as

\[
R(t, \tilde{t}) = \left\langle \left\langle g_b(\hat{h}_\mu(t-1)) \; g_b(\hat{h}_\mu(\tilde{t}-1)) \right\rangle \right\rangle \quad t, \tilde{t} \geq 1
\] (46)

\[
R(t, 0) = \left\langle \left\langle \sigma(0) g_b(\hat{h}_\mu(t-1)) \right\rangle \right\rangle \quad t \geq 1.
\] (47)

This is based on the fact that by definition of the modified local field \( \{\xi_\mu_i, g_b(\hat{h}_\mu(0))\} \) and \( \{\xi_\mu_i, \sigma_i(0)\} \), become a set of uncorrelated variables. These results lead to the recursion relation (recall eq. (28))

\[
D(2) = \frac{a(2)}{A} + \chi^2(1) D(1) + 2 \frac{\chi(1)}{A} (R(2, 1) + \chi(0) R(2, 0)).
\] (48)

We still have to determine the \( R(t, \tilde{t}) \). The correlation \( R(2, 0) \) can be written down immediately again by using the definition of the modified local field at \( t = 1 \)

\[
R(2, 0) = \left\langle \left\langle \sigma(0) \int Dz \; g_b \left( \xi^1 m^1(1) + \alpha \chi(0) \sigma(0) + \sqrt{\alpha AD(1)} z \right) \right\rangle \right\rangle .
\] (49)
To obtain $R(2, 1)$, one remarks that due to the dependence of $\sigma_i(0)$ and $\sigma_i(1)$ the local fields $h_i(1)$ and $h_i(0)$ are correlated. The correlation coefficient of their normally distributed part in general defined as

$$
\rho(t, \tilde{t}) \equiv \frac{\mathbb{E}[(h(t) - M(t))(h(\tilde{t}) - M(\tilde{t}))]}{\sqrt{V(t)} \sqrt{V(\tilde{t})}}
$$

is found using the recursion formula (50)

$$
\rho(1, 0) = \frac{\alpha R(1, 0) + \alpha A \chi(0) D(0)}{\sqrt{\alpha AD(0) \sqrt{\alpha AD(1)}}}.
$$

Employing all this in eq. (46) we arrive at

$$
R(2, 1) = \int \mathcal{D}w^{1,0}(x, y) \ g_b \left( \xi^1 m^1(0) + \sqrt{\alpha AD(0)} x \right) \times g_b \left( \xi^1 m^1(1) + \alpha \chi(0) \sigma(0) + \sqrt{\alpha AD(1)} y \right).
$$

Here the joint distribution $\mathcal{D}w^{1,0}(x, y)$ equals

$$
\mathcal{D}w^{1,0}(x, y) = \frac{dx \ dy}{2\pi \sqrt{1 - \rho(1, 0)^2}} \exp \left( -\frac{x^2 - 2\rho(1, 0)xy + y^2}{2(1 - \rho(1, 0)^2)} \right).
$$

We remark that, for $Q = 2$, the result is slightly different from the corresponding result in [14] (see, e.g., their eq.(39)). In more detail, in their approach these authors make an ansatz stating the independence of the normally distributed and discrete part in the noise arising from $t \geq 2$ onwards. They explicitly state that they have no convincing arguments in favour of (as well as against) this ansatz for $t \geq 2$. In our approach we do not need this ansatz. This results in a more complicated expression for $R(2, 1)$ than the corresponding one found in [14], indicating that this ansatz really ignores some correlations. In fact both expressions coincide if we put $\rho(1, 0)$ equal to zero.

### 4.3 Third step dynamics

We start by writing down the distribution of the local field at time $t = 2$. From eqs. (31) and (32) we find

$$
h_i(2) = \xi^1 m^1(2) + \alpha \chi(1) [\sigma_i(1) + \chi(0) \sigma_i(0)] + \mathcal{N}(0, \alpha AD(2)) \ .
$$
This gives for the main overlap

\[ m^1(3) = \frac{1}{A} \left\langle \left\langle \xi^1 g_b \left( \xi^1 m^1(2) + \alpha \chi(1) [\sigma(1) + \chi(0)\sigma(0)] + \sqrt{\alpha AD(2)} y \right) \right\rangle \right\rangle \]

(55)

with \( y \) the Gaussian random variable \( \mathcal{N}(0,1) \). The average has to be taken over \( y, \sigma_i(0) \) and \( \sigma_i(1) \). The average over \( \sigma_i(0) \) causes no difficulties because this initial configuration is chosen randomly. The average over \( y \), the Gaussian random variable appearing in \( h_i(2) \), and \( \sigma_i(1) \) is more tricky because \( h_i(2) \) and \( \sigma_i(1) \) are correlated by the dynamics. However, the evolution equation (4) tells us that \( \sigma_i(1) \) can be replaced by \( g_b(h_i(0)) \) and, hence, the average taken over \( h_i(0) \) instead of \( \sigma_i(1) \).

From the recursion relation (29) one finds for the correlation coefficient between \( h_i(0) \) and \( h_i(2) \)

\[ \rho(2,0) = \frac{\alpha [R(2,0) + \chi(1) [R(1,0) + \chi(0)a(0)]]}{\sqrt{\alpha AD(0)\sqrt{\alpha AD(2)}}}. \]

(56)

Using all this the main overlap at the third time step (55) becomes

\[
m^1(3) = \frac{1}{A} \left\langle \left\langle \xi^1 \int D^{2,0}(x,y) g_b \left( \xi^1 m^1(2) + \alpha \chi(1) \left[ g_b(\xi^1 m^1(0) + \sqrt{\alpha AD(0)} x) + \chi(0)\sigma(0) \right] + \sqrt{\alpha AD(2)} y \right) \right\rangle \right\rangle
\]

(57)

where the joint distribution of \( x \) and \( y \) equals

\[ D^{2,0}(x,y) = \frac{dx \, dy}{2\pi \sqrt{1 - \rho(2,0)^2}} \exp \left( -\frac{x^2 - 2\rho(2,0)xy + y^2}{2(1 - \rho(2,0)^2)} \right). \]

(58)

In an analogous way one arrives at the expression for the activity at the third time step

\[
a(3) = \left\langle \left\langle \int D^{2,0}(x,y) g_b^2 \left( \xi^1 m^1(2) + \alpha \chi(1) \left[ g_b(\xi^1 m^1(0) + \sqrt{\alpha AD(0)} x) + \chi(0)\sigma(0) \right] + \sqrt{\alpha AD(2)} y \right) \right\rangle \right\rangle.
\]

(59)
In order to find the variance of the residual overlap at the third time step, \( D(3) \), we start by rewriting eq. (28) as

\[
D(3) = \frac{a(3)}{A} + \chi^2(2) + 2\frac{\chi(2)}{A} (R(3, 2) + \chi(1) (R(3, 1) + \chi(0)R(3, 0)))
\]  

(60)

with

\[
\chi(2) = \langle \frac{1}{\sqrt{\alpha AD(2)(1 - \rho(2, 0)^2)}} \int Dz \int Dy g_b(\xi^1 m(2) \\
+ \alpha \chi(1) \left( g_b(\xi^1 m(0) + \sqrt{\alpha AD(0) y}) + \chi(0)\sigma(0) \right) \\
+ \sqrt{\alpha AD(2)(1 - \rho(2, 0)^2)} z + \sqrt{\alpha AD(2) \rho(2, 0) y}) \rangle \rangle.
\]  

(61)

Here we have used the recursion relation (25) for \( r^\mu(2) \) and the fact that \( \{\xi^\mu_i, g_b(\hat{h}^\mu_i(0))\}_i \) and \( \{\xi^\mu_i, \sigma_i(0)\}_i \) become a collection of uncorrelated variables for \( \mu \in P \setminus \{1\} \). We then have to calculate the correlations \( R(3, 0) \), \( R(3, 1) \) and \( R(3, 2) \). From the definition (18), the local field (54) and the joint distribution (58) one easily arrives at

\[
R(3, 0) = \left\langle \left\langle \sigma(0) \int Dw^{2,0}(x, y) g_b(\xi^1 m(2) + \\
\alpha \chi(1) \left[ g_b(\xi^1 m(0) + \sqrt{\alpha AD(0) x}) + \chi(0)\sigma(0) \right] + \sqrt{\alpha AD(2) y} \right) g_b(\xi^1 m(2) + \\
\alpha \chi(1) \left[ g_b(\xi^1 m(0) + \sqrt{\alpha AD(0) x}) + \chi(0)\sigma(0) \right] + \sqrt{\alpha AD(2) y} \right) \right\rangle \rangle.
\]  

(62)

\[
R(3, 1) = \left\langle \left\langle \int Dw^{2,0}(x, y) g_b(\xi^1 m(0) + \sqrt{\alpha AD(0) x}) g_b(\xi^1 m(2) + \\
\alpha \chi(1) \left[ g_b(\xi^1 m(0) + \sqrt{\alpha AD(0) x}) + \chi(0)\sigma(0) \right] + \sqrt{\alpha AD(2) y} \right) \right\rangle \rangle.
\]  

(63)

Finding \( R(3, 2) \) is more tricky since, after rewriting the network configurations \( \{\sigma_i(t)\} \) at time \( t = 1 \) and \( t = 2 \) by means of the gain function (4), the local fields at the three first time steps appear. So one has to calculate the elements of the correlation matrix of these local fields in general defined by

\[
C(t, \tilde{t}) \equiv \sqrt{\alpha AD(t) \rho(t, \tilde{t})}.
\]  

(64)

The correlation coefficients \( \rho(1, 0) \) and \( \rho(2, 0) \) have been calculated already before (recall eqs. (54) and (60)). The correlation coefficient \( \rho(2, 1) \) of \( h(2) \) and \( h(1) \) is found by using the recursion relation (28) as

\[
\rho(2, 1) = \frac{\alpha [R(2, 1) + \chi(1)AD(1)]}{\sqrt{\alpha AD(2) \rho(2, 0) y}}.
\]  

(65)
The distribution function $D^{w^{1},2}(x, y, z)$ of the three local fields equals

$$D^{w^{1},2}(x, y, z) = \frac{dx \, dy \, dz}{(2\pi)^{3/2} \sqrt{\text{Det} w^{1,2}}} \exp \left( -\frac{1}{2} \begin{pmatrix} x \\ y \\ z \end{pmatrix} (w^{1,2})^{-1} \begin{pmatrix} x \\ y \\ z \end{pmatrix} \right)$$

where

$$w^{1,2} = \begin{pmatrix} \alpha AD(0) & C(1,0) & C(2,0) \\ C(1,0) & \alpha AD(1) & C(2,1) \\ C(2,0) & C(2,1) & \alpha AD(2) \end{pmatrix}.$$  \hspace{1cm} (66)

Finally, using all this information one gets for the correlation parameter $R(3,2) = \langle \left\langle \int D^{w^{1},2}(x, y, z) g_b \left( \xi^1 m^1(1) + \alpha \chi(0) \sigma(0) + y \right) \right. $

$$g_b \left( \xi^1 m^1(2) + \alpha \chi(1) \left[ g_b \left( \xi^1 m^1(0) + x \right) + \chi(0) \sigma(0) \right] + z \right) \rangle \right\rangle. \hspace{1cm} (68)$$

These results can be compared with those for extremely diluted systems. If the dilution is symmetric (see refs. [5],[6] for the case $Q = 2$) feedback loops over two time steps can exist, but the probability to have loops over a longer time period equals zero. Therefore the $\sigma_i(0)$-term in (54) drops out. Furthermore in the $Q = 2$ case the expression for the correlation coefficient (50) simply reads $\rho(2,0) = R(2,0)$. If the dilution is asymmetric [8], all feedback disappears and the local field is simply Gaussian distributed.

## 5 Fixed-point equations

A second type of results can be obtained by requiring through the recursion relations (28), (31) and (32) that the local field becomes stationary. We show that this leads to the same fixed-point equations as those found from thermodynamics in [21].

For the Q-Ising model at zero temperature one can show that

$$H(t) = -\frac{1}{4} \sum_{i \in \Lambda} \left( \sum_{j \in \Lambda} J_{ij} \sigma_j(t) \bar{\sigma}_i(t) - b(\bar{\sigma}_i^2(t) + \sigma_i^2(t)) \right) \hspace{1cm} (69)$$

with $\bar{\sigma}_i(t)$ chosen such that

$$\epsilon_i[\bar{\sigma}_i(t) | \sigma_{\Lambda \setminus \{i\}}(t)] = \min_{s \in S} \epsilon_i[s | \sigma_{\Lambda \setminus \{i\}}(t)]. \hspace{1cm} (70)$$
is a Lyapunov function. For finite \( N \), \( H(t) \) is bounded from below implying that \( H(t+1) - H(t) = 0 \) after finitely many time steps. This can be realized for \( \sigma_i(t+2) = \sigma_i(t) \) \( \forall i \in \Lambda \). The proof is straightforward and completely analogous to the argumentation used in \cite{16,17}. Both a fixed point and a two-cycle satisfy this condition. As stated in the introduction we only study fixed-points.

Since the evolution equations for the order parameters in the extremely diluted and layered \( Q \)-Ising models do not change their form as time progresses, the fixed-point equations are obtained immediately by leaving out the time dependence (see \cite{2,4}). This still allows small fluctuations in the configurations \( \{\sigma_i\} \).

Since in the fully connected model treated here the form of the evolution equations for the order parameters do change by the explicit appearance of the \( \{\sigma_i(t)\}, t \geq 0 \), we can not use that procedure to obtain the fixed-point equations. Instead we require that the distribution of the local field becomes independent of time. This is a stronger condition because fluctuations in the network configuration are no longer allowed. Consequently, the main overlap and activity in the fixed-point are found from the definitions (7), (8) and not from leaving out the time dependence in the recursion relation (13) and (14). The same line of reasoning is followed in, e.g., \cite{24,25}.

We start by eliminating the time-dependence in the evolution equations for the local field (29). This leads to

\[
 h_i = \xi^1_{i} m^1 + \frac{1}{1 - \chi} N(0, \alpha a) + \alpha \chi \sigma_i
\]  

with \( h_i \equiv \lim_{t \to \infty} h_i(t) \). This expression consists out of two parts: a normally distributed part \( h_i = N(\xi^1_{i} m^1, \alpha a/(1 - \chi)^2) \) and some discrete noise part. We remark that this discrete noise coming from the correlation of the \( \{\sigma_i(t)\} \) at different time steps is inherent in the fully connected dynamics.

Employing the expression eq. (71) in the updating rule (4) one finds

\[
 \sigma_i = g_b(\bar{h}_i + \alpha \eta \sigma_i) \quad \eta = \chi/(1 - \chi).
\]  

This is a self-consistent equation in \( \sigma_i \) which in general admits more than one solution. This type of equation has been solved in the case of analog neural networks with continuous time dynamics using a Maxwell construction \cite{24,25}. Such a construction is standard in thermodynamics in order to maximize the exponent of the integrand appearing in free energy calculations. Here we use a similar geometrical construction to treat eq. (72).
Let $L$ be the straight line which connects the centers of the plateaus of the gain function $g_b(\cdot)$. The equations for the functions $g_b(\cdot)$ and $L(\cdot)$ read

$$
g_b : x \mapsto s_k \text{ if } b(s_k + s_{k-1}) < x < b(s_k + s_{k+1}) \tag{73}$$

$$
L : x \mapsto \frac{x}{2b} \tag{74}
$$

The condition on the r.h.s. of (73) is a condition on $x$. Using the definition of $L(\cdot)$, one can transform this into a condition on the image of $L(\cdot)$, $\mathcal{I}_L = \{y \in \mathbb{R} \mid \exists x \in \mathbb{R} : L(x) = y\}$, viz.

$$
g_b(x) = s_k \text{ if } \frac{s_k + s_{k-1}}{2} < L(x) < \frac{s_k + s_{k+1}}{2} \tag{75}
$$

Consider the transformation $\mathcal{T} : (x, y) \mapsto (x - \alpha \eta y, y)$

$$
\mathcal{T}(L) : x \mapsto \frac{x}{2(b - \frac{\alpha \eta}{2})} \tag{76}
$$

The function $\mathcal{T}(g_b)(\cdot)$ is not bijective while $\mathcal{T}$ is not one-to-one. To obtain a unique solution for eq. (72) we modify the former function such that it becomes a step function with the same step height as the one in $\mathcal{T}(g_b)(\cdot)$ and the width of the steps such that $\mathcal{T}(L)$ connects the centers of the plateaus:

$$
\mathcal{T}_L(g_b)(x) = s_k \text{ if } (b - \frac{\alpha \eta}{2})(s_k + s_{k-1}) < x < (b - \frac{\alpha \eta}{2})(s_k + s_{k+1}) \tag{77}
$$

or, using (4)

$$
\mathcal{T}_L(g_b)(x) = g_b(\tilde{b}) \text{ with } \tilde{b} = b - \frac{\alpha \eta}{2} \tag{78}
$$

This at first sight ad-hoc modification leads us to a unique solution of the self-consistent equation (72). Indeed, from this modified transformation we know that

$$
g_b(\tilde{h} + \alpha \eta \sigma) \simeq g_b(\tilde{h} + \alpha \eta \sigma - \alpha \eta g_b(\tilde{h} + \alpha \eta \sigma)) \tag{79}
$$

such that

$$
\sigma_i = g_b(\tilde{h}_i) \tag{80}
$$

At this point we remark that plugging this result into the local field equation (71) tells us that the latter is the sum of two Gaussians with shifted mean (see also [12]).
Using the definition of the main overlap and activity (7) and (8) in the limit \( N \to \infty \), one finds in the fixed point

\[
m^1 = \left \langle \left \langle \xi^1 \int \mathcal{D}z \ g_0 \left ( \xi^1 m^1 + \sqrt{\alpha AD} z \right ) \right \rangle \right \rangle
\] (81)

\[
a = \left \langle \left \langle \int \mathcal{D}z \ g_0^2 \left ( \xi^1 m^1 + \sqrt{\alpha AD} z \right ) \right \rangle \right \rangle.
\] (82)

From (25), (28) and (27) it is clear that

\[
D = \frac{a/A}{(1 - \chi)^2}
\] (83)

with

\[
\chi = \frac{1}{\sqrt{\alpha AD}} \left \langle \left \langle \int \mathcal{D}z \ z \ g_0 \left ( \xi^1 m^1 + \sqrt{\alpha AD} z \right ) \right \rangle \right \rangle.
\] (84)

These resulting equations (81)-(83) are the same as the fixed-point equations derived from a replica-symmetric mean-field theory treatment in [21]. Their solution leads to the \( \alpha - b \) phase diagram Fig. 1b in [21]. We end with the observation that for analog networks the construction (73)-(78) is not necessary: the fixed-point equation (72) has only one solution.

6 Numerical simulations

As an illustrative example the equations derived in Section 4 have been worked out explicitly in the case of the \( Q = 3 \) model with equidistant states and a uniform distribution of the patterns \( (A = 2/3) \).

For this model a thermodynamic replica-symmetric mean-field theory approach leads to a capacity-gain replica-symmetric mean-field theory diagram discussed already in [21] (Fig. 1b). As explained in Section 5 the same phase diagram can be obtained through the dynamical approach presented here. For convenience and completeness this phase diagram is reproduced here as Fig. 1. At this point it is also useful to recall that there are two types of retrieval states. In region I the mean-square random overlap with the non-condensed patterns, \( r \), is of order \( O(1) \) while in region II \( r \) is of order \( O(10) \) [21].

For specific network parameters corresponding to different points in the retrieval region of this equilibrium phase diagram, indicated as 1 to 4, we have compared the dynamics governed by the evolution equations found here with
extensive simulations involving system-sizes up to $N = 6000$ (each data point is averaged over 1600 runs).

Figures 2-5 present an overview of these results by plotting the overlap $m^1(t)$, the activity $a(t)$ and the Hamming distance $d(t)$ versus the initial overlap $m^1_0$ with the condensed pattern. (We forget about the superscript 1). The initial activity is taken to be $a_0 = 0.85$.

First we consider region I. For network parameters corresponding to point 1 below the thermodynamic transition line, i.e., $\alpha = 0.005, b = 0.3$, we see in Fig. 2 that for $m_0 \geq 0.33$ the dynamics quickly evolves to an overlap $m = 1$ and that the Hamming distance is zero for $m_0 \geq 0.37$. The activity attains the value $2/3$, meaning that the network configuration is uniformly distributed. The boundary between the $m = 1$ attractor and the zero-attractor is rather sharply determined.

For a network corresponding to point 2 above the thermodynamic transition line, with $\alpha = 0.03, b = 0.5$, we need a larger value of $m_0$ to reach the $m = 1$ attractor and a Hamming distance zero. As seen in Fig. 3, $m_0$ has to be at least $0.75$. Also the boundary between the $m = 1$ attractor and the zero-attractor is less sharply determined. Figure 4 shows that this behavior is qualitatively the same for $\alpha = 0.009, b = 0.7$, corresponding to point 3 situated above the spin-glass transition in the phase diagram. In this case the value of $m_0$ has to be at least $0.85$. For the other network parameters we have looked at, e.g., $\alpha = 0.0115, b = 0.5$ the global behavior is similar.

For network parameters corresponding to points in region II of the phase diagram, e.g., point 4 with $\alpha = 0.015, b = 0.1$ it is shown in Fig. 5 that the main overlap goes to its maximum value for almost all values of $m_0$. The basin of attraction of the zero fixed-point is zero. The activity, however, goes to a value larger than $2/3$. The network configuration is no longer uniformly distributed: the state $\sigma_i = 0$ has a smaller probability to appear than the states $\sigma_i = \pm 1$. Hence, the Hamming distance is never zero. This must be due to the fact that the influence of the non-condensed patterns is much larger here ($r \approx O(10)$). The same qualitative behavior is found for network parameters corresponding to points in region II below the thermodynamic transition line, e.g., $\alpha = 0.005, b = 0.1$. 
7 Concluding remarks

In this paper we have derived the evolution equation for the distribution of the local field governing the parallel dynamics at zero temperature of fully connected $Q$-Ising networks, taking into account all feedback correlations. This leads to a general recursive scheme which allows us to calculate the relevant order parameters of the system, i.e., the main overlap, the activity and the variance of the residual overlap, for any time step. We have worked out this scheme explicitly for the first three time steps of the dynamics.

Under the condition that the local field becomes stationary we have also obtained the fixed-point equations for these order parameters. They are found to be the same as those derived via thermodynamic methods [21].

As an illustration we have presented a detailed discussion of these results for the $Q = 3$-model and we have made a comparison with extensive numerical simulations. It is seen that these numerical results provide excellent support for our theoretical predictions and that the first three time steps do give already a clear picture of the time evolution in the retrieval regime of the network.
