Sparse Grid Discontinuous Galerkin Methods for High-Dimensional Elliptic Equations

Zixuan Wang ∗ Qi Tang † Wei Guo ‡ Yingda Cheng §

September 1, 2015

Abstract

This paper constitutes our initial effort in developing sparse grid discontinuous Galerkin (DG) methods for high-dimensional partial differential equations (PDEs). Over the past few decades, DG methods have gained popularity in many applications due to their distinctive features. However, they are often deemed too costly because of the large number of degrees of freedom of the approximation space, which are the main bottleneck for simulations in high dimensions. In this paper, we develop sparse grid DG methods for elliptic equations with the aim of breaking the curse of dimensionality. Using a hierarchical basis representation, we construct a sparse finite element approximation space, reducing the degrees of freedom from the standard $O(h^{-d})$ to $O(h^{-1} \log_2 h |d-1|)$ for $d$-dimensional problems, where $h$ is the uniform mesh size in each dimension. Our method, based on the interior penalty (IP) DG framework, can achieve accuracy of $O(h^k \log_2 h |d-1|)$ in the energy norm, where $k$ is the degree of polynomials used. Error estimates are provided and confirmed by numerical tests in multi-dimensions.

Keywords: discontinuous Galerkin methods; interior penalty methods; sparse grid; high-dimensional partial differential equations.

1 Introduction

Elliptic equations have been used successfully in many areas of modeling, such as aeroacoustics, electro-magnetism, oil recovery simulation, weather forecasting, etc. Their numerical...
treatment includes the standard finite difference methods, collocation methods, Galerkin finite element methods, least squares methods, among many others. Discontinuous Galerkin (DG) methods work well for purely hyperbolic problems due to the discontinuous nature of the solutions. Yet, they are also proven to be effective for elliptic equations. Since the 1970s, the interior penalty (IP) DG methods have been proposed \cite{8, 24, 56, 5} and generalized \cite{45, 47, 22}. A review of DG methods for elliptic equations including discussions about other DG methods, such as the method of Bassi and Rebay \cite{9}, and the local DG (LDG) method \cite{21, 17, 19}, can be found in \cite{6}. It is generally understood that the advantages of DG methods lie in their flexibility in choosing the discretization meshes and the approximation spaces. However, the methods are often deemed too costly due to the large degrees of freedom of the approximation space. Such drawback is more prominent when dealing with high-dimensional equations arising from real-world applications, such as kinetic simulations, stochastic analysis, and mathematical modeling in finance or statistics.

This paper concerns the computation of high-dimensional elliptic equations, for which the main challenge is commonly known as the curse of dimensionality \cite{11}. This term refers to the fact that the computational cost and storage requirements scale as $O(h^{-d})$ for a $d$-dimensional problem, where $h$ denotes the mesh size in one coordinate direction. This challenge typically can not be resolved through barely increasing computational resources, and it requires the improvement of numerical techniques as well as efficient computational implementations. The sparse grid techniques \cite{15, 25}, introduced by Zenger \cite{60}, have been developed as a major tool to break the curse of dimensionality of grid-based approaches. The idea relies on a tensor product hierarchical basis representation, which can reduce the degrees of freedom from $O(h^{-d})$ to $O(h^{-1} \log_2 h |^{d-1})$ for $d$-dimensional problems without compromising much accuracy. The fundamentals of sparse grid techniques can be traced back to Smolyak \cite{51} for numerical integration, and they are closely related to hyperbolic cross \cite{7, 52}, boolean method \cite{23}, discrete blending method \cite{10}, and splitting extrapolation method \cite{40} in the literature. The construction of the scheme is based on balancing the cost complexities and the accuracy of the scheme by seeking a proper truncation of the tensor product hierarchical bases, which can be formally derived by solving an optimization problem of cost/benefit ratios \cite{31}. Sparse grid techniques have been incorporated in collocation methods for high-dimensional stochastic differential equations \cite{53, 57, 44, 41}, Galerkin finite element methods \cite{60, 15, 48}, finite difference methods \cite{30, 55}, finite volume methods \cite{37}, and spectral methods \cite{32, 28, 49, 50} for high-dimensional PDEs. However, their potential has not yet been fully realized under the DG framework, which constitutes the main focus of this paper.

Generally speaking, the design of DG methods has two essential ingredients: (1) a (weak) formulation of the methods based on the underlying PDE, (2) a suitable approximation space. The appropriate choice of the formulation of the scheme as well as approximation properties of the discrete space can guarantee the methods with desirable properties such as stability and convergence. In fact, DG formulations based on traditional piecewise polynomial space have been extensively studied for the last few decades, and the methods are rather mature for various applications. As for the approximation spaces, DG methods are more flexible compared with continuous finite element methods due to the lack of continuity requirement.
In recent years, the ideas of using nonstandard spaces such as non-polynomial spaces \cite{59, 54}, or polynomial spaces with specific properties such as locally divergence-free properties \cite{20} have been explored. They are mainly driven by the needs to mimic particular properties of the exact solution. In this paper, we aim at incorporating the sparse grid approximation spaces in the DG framework to treat high-dimensional problems. As an initial effort in our investigation, we focus on high-dimensional elliptic problems and develop a sparse grid DG method for the following $d$-dimensional model problem

$$- \nabla \cdot (K \nabla u) = f \quad \text{in } \Omega = [0, 1]^d,$$  \hspace{1cm} (1)

with a Dirichlet boundary condition

$$u = g \quad \text{on } \partial \Omega,$$  \hspace{1cm} (2)

where $u(x) : \Omega \to \mathbb{R}$ is the unknown function and the matrix-valued coefficient function $K = (k_{i,j})_{1 \leq i,j \leq d}$ is symmetric positive definite and bounded below and above uniformly, i.e. there exist two positive constant $K_0, K_1$, such that

$$\forall x \in \Omega, \quad K_0 \, x \cdot x \leq K \, x \cdot x \leq K_1 \, x \cdot x.$$

Using a hierarchical basis representation, we construct a sparse finite element approximation space, reducing the degrees of freedom from the standard $O(h^{-d})$ to $O(h^{-1} |\log_2 h|^{d-1})$ for $d$-dimensional problems, where $h$ is the uniform mesh size in each dimension. Based on the IPDG framework and careful implementation, the new approximation space enables an efficient solver for the model equation. A priori error estimate shows that the proposed method is convergent in the order of $O(h^k)$ up to the polylogarithmic term $|\log_2 h|^{d-1}$ in the energy norm when the solution is smooth enough, where $k$ is the degree of the polynomial space.

Although the method in this paper is restricted to problems on a box-shaped domain, it has the potential to be implemented on general domains by considering either a coordinate transformation or a more complex sparse finite element space based on hierarchical decompositions on unstructured meshes.

The rest of this paper is organized as follows: in Section 2, we construct and analyze the DG approximation space on sparse grids. In Section 3, we formulate the scheme and perform error analysis of the sparse grid IPDG method. Implementation details will be discussed to ensure computational efficiency. In Section 4, numerical examples in multi-dimensions (up to $d = 4$) are provided to validate the accuracy and performance of the method. Conclusions and future work are given in Section 5.

2 DG Finite Element Spaces on Sparse Grids

In this section, we introduce the main ingredient of our algorithm: the DG finite element space on sparse grids. We proceed in several steps. First, we review the standard piecewise polynomial spaces in one dimension, and introduce a hierarchical decomposition with a
set of orthonormal bases. Second, we construct the sparse finite element space from multi-dimensional multiwavelet bases as tensor products from the one-dimensional construction. Finally, we discuss some key features and approximation properties of the sparse finite element space. Numerical tests are given to compare several definitions of sparse discontinuous finite element spaces.

2.1 Hierarchical Decomposition of Piecewise Polynomial Spaces in One Dimension

In this subsection, we will introduce the hierarchical representation of piecewise polynomial spaces in one dimension. Many discussions here are closely related to the original Haar wavelet [36], the multiwavelet bases constructed in [2, 3], and multiresolution analysis (MRA) with DG methods for adaptivity [16, 4, 39, 38, 26] and constructions of trouble-cell indicator [53], the multiwavelet bases constructed in [2, 3], and multiresolution analysis (MRA) with spaces in one dimension. Many discussions here are closely related to the original Haar wavelet [36], the multiwavelet bases constructed in [2, 3], and multiresolution analysis (MRA) with DG methods for adaptivity [16, 4, 39, 38, 26] and constructions of trouble-cell indicator [53] for hyperbolic conservation laws.

Without loss of generality, consider the interval \( \Omega = [0, 1] \), we define the \( n \)-th level grid \( \Omega_n \), consisting of \( I^n_j = (2^{-n}j, 2^{-n}(j + 1)) \), \( j = 0, \ldots, 2^n - 1 \) with uniform cell size \( h = 2^{-n} \). On this grid, we use \( \| \cdot \|_{H^s(\Omega_n)} \) to denote the broken Sobolev norm, i.e. \( \|v\|^2_{H^s(\Omega_n)} = \sum_{j=0}^{2^n-1} |v|^2_{H^s(I^n_j)} \), where \( |v|^2_{H^s(I^n_j)} \) is the standard Sobolev norm on \( I^n_j \). Similarly, \( |\cdot|_{H^s(\Omega_n)} \) denotes the broken Sobolev semi-norm, i.e. \( |v|^2_{H^s(\Omega_n)} = \sum_{j=0}^{2^n-1} |v|^2_{H^s(I^n_j)} \).

We can define

\[
V^k_n = \{ v : v \in P^k(I^n_j), \forall j = 0, \ldots, 2^n - 1 \}
\]

to be the usual piecewise polynomials of degree at most \( k \) on this grid. Clearly, \( V^k_n \) has degrees of freedom \( 2^n(k + 1) \), and we notice that they have the nested structure for different values of \( n \),

\[
V^0_n \subset V^1_n \subset V^2_n \subset V^3_n \subset \cdots
\]

Due to this nested structure, we can define the multiwavelet subspace \( W^k_n, n = 1, 2, \ldots \) as the orthogonal complement of \( V^k_{n-1} \) in \( V^k_n \) with respect to the \( L^2 \) inner product on \( \Omega \), i.e.

\[
V^k_{n-1} \oplus W^k_n = V^k_n, \quad W^k_n \perp V^k_{n-1}.
\]

For notational convenience, we also denote the base space \( W^k_0 := V^k_0 \), which consists of all polynomials of up to degree \( k \) on \( [0, 1] \). The dimension of \( W^k_0 \) is \( 2^{n-1}(k + 1) \) when \( n \geq 1 \), and \( k + 1 \) when \( n = 0 \). Now, we have found a hierarchical representation of the standard piecewise polynomial space on grid \( \{ I^n_j, j = 0, \ldots, 2^n - 1 \} \) as \( V^k_N = \bigoplus_{0 \leq n \leq N} W^k_n \). We remark that the space \( W^k_n \), for \( n > 1 \), represents the finer level details when the mesh becomes refined and this is the key to the reduction in degrees of freedom in higher dimensions.

For implementation purpose, we need to introduce basis functions for space \( W^k_n \). The case of \( n = 0 \) is trivial. It suffices to use a standard polynomial basis on \( \Omega \). For example, by using the scaled Legendre polynomials, we can easily obtain a set of orthonormal bases in \( W^k_0 \). When \( n > 1 \), we will use the orthonormal bases introduced in [2]. In particular, the bases for \( W^k_1 \) are defined as

\[
h_i(x) = 2^{1/2} f_i(2x - 1), \quad i = 1, \ldots, k + 1
\]
where \( \{ f_i(x), i = 1, \ldots, k + 1 \} \) are functions supported on \([-1, 1]\) depending on \(k\), with the following properties.

1. The restriction of \(f_i\) to the interval \((0, 1)\) is a polynomial of degree \(k\).

2. The function \(f_i\) is extended to \((-1, 0)\) as an even or odd function according to the parity of \(i + k\):
   \[
f_i(x) = (-1)^{i+k} f_i(-x).
   \]

3. The bases have vanishing moments:
   \[
   \int_{-1}^{1} f_j(x) x^i \, dx = 0 \quad i = 0, 1, \ldots, j + k - 1.
   \]

4. The bases have the orthogonality and normality properties:
   \[
   \int_{-1}^{1} f_i(x) f_j(x) \, dx = \delta_{ij}, \quad i, j = 1, \ldots, k.
   \]

Functions \(\{f_i\}\) can be computed by a repeated Gram-Schmidt algorithm. The particular form of \(\{f_i\}\) up to \(k = 4\) are listed in Table 1 in [2]. Multiwavelet bases in [2] retain the orthonormal properties of wavelet bases for different hierarchical levels by introducing the basis for \(W^k_n, n \geq 1\) as

\[
v_{i,n}^j(x) = 2^{(n-1)/2} h_i(2^{n-1}x - j), \quad i = 1, \ldots, k + 1, \; j = 0, \ldots, 2^n - 1 - 1.
\]

To make the notations consistent and compact, when \(n = 0\), the bases \(v_{0,0}^i(x), i = 1, \ldots, k+1\) are defined as the rescaled Legendre polynomials on \([0, 1]\) with orthonormal property. In summary, we have [2, 3],

\[
\int_{0}^{1} v_{i,n}^j(x) v_{i',n'}^{j'}(x) \, dx = \delta_{ii'} \delta_{nn'} \delta_{jj'},
\]

where \(\delta_{ii'}, \delta_{nn'}, \delta_{jj'}\) are the Kronecker delta symbols.

Next, we will discuss about the projection operators that are essential in finite element analysis. We define \(P^k_n\) as the standard univariate \(L^2\) projection operator from \(L^2[0, 1]\) to \(V^k_n\). From there, we can introduce the increment projector,

\[
Q^k_n := \begin{cases} 
  P^k_n - P^k_{n-1}, & \text{if } n \geq 1 \\
  P^k_0 & \text{if } n = 0,
\end{cases}
\]

then we can see that

\[
W^k_n = Q^k_n L^2(0, 1).
\]
In summary, we arrive at the following identities for the hierarchical decomposition of the piecewise polynomial space and the projection operator:

\[ V^k_N = \bigoplus_{0 \leq n \leq N} W^k_n, \quad P^k_N = \sum_{0 \leq n \leq N} Q^k_n. \]

The properties of \( Q^k_n \) naturally rely on \( P^k_n \). For the \( L^2 \) projection operators, we recall the following approximation results.

**Property 2.1 (Convergence Property of the Projection Operator [18])** For a function \( v \in H^{p+1}(0,1) \), we have the convergence property of the \( L^2 \) projection \( P^k_n \) as follows: for any integer \( t \) with \( 1 \leq t \leq \min\{p,k\} \), and \( s \leq t + 1 \),

\[
\| P^k_n v - v \|_{H^s(\Omega)} \leq c_{k,s,t} 2^{-n(t+1-s)} \| v \|_{H^{t+1}(\Omega)},
\]

where \( c_{k,s,t} \) is a constant that depends on \( k, s, t \), but not on \( n \).

From this property, using basic algebra, we can deduce that for \( n \geq 1 \),

\[
\| Q^k_n v \|_{H^s(\Omega)} \leq \tilde{c}_{k,s,t} 2^{-n(t+1-s)} \| v \|_{H^{t+1}(\Omega)},
\]

with

\[
\tilde{c}_{k,s,t} = c_{k,s,t} (1 + 2^{-(t+1-s)}). \tag{4}
\]

Finally, we want to remark on a subtle issue concerning the hierarchical decomposition and the multiwavelet space. If we use a projection other than \( P^k_n \), say \( \hat{P}^k_n \) is another projection from \( L^2(\Omega) \) to \( V^k_n \). Then the increment projector \( \hat{Q}^k_n \neq Q^k_n \). The space \( \hat{W}^k_n = \hat{Q}^k_n L^2(0,1) \) is different from \( W^k_n \), and likewise for the multiwavelet bases. However, the hierarchical structure \( V^k_{n-1} \oplus W^k_n = V^k_n \) still holds. In our discussion in the next subsection, we will highlight the implication of this statement and show that using different definitions of the projector and the increment space will not affect the definition of the sparse discontinuous finite element space in multi-dimensions.

### 2.2 Sparse Discontinuous Finite Element Spaces in Multi-dimensions

In this subsection, we introduce the sparse finite element space constructed from multi-dimensional multiwavelet bases obtained from tensor products of the one-dimensional bases in Section 2.1.

For a \( d \)-dimensional problem, we consider the domain \( \mathbf{x} = (x_1, \ldots, x_d) \in \Omega = [0,1]^d \). To facilitate the discussion, we first introduce some notations on the norms and operations of multi-indices in \( \mathbb{N}_0^d \), where \( \mathbb{N}_0 \) denotes the set of nonnegative integers. For \( \alpha = (\alpha_1, \ldots, \alpha_d) \in \mathbb{N}_0^d \), we define the \( l^1 \) and \( l^\infty \) norms

\[
|\alpha|_1 := \sum_{m=1}^d \alpha_m, \quad |\alpha|_\infty := \max_{1 \leq m \leq d} \alpha_m,
\]
the component-wise arithmetic operations

\[ \alpha \cdot \beta := (\alpha_1 \beta_1, \ldots, \alpha_d \beta_d), \quad c \cdot \alpha := (c \alpha_1, \ldots, c \alpha_d), \quad 2^{\alpha} := (2^{\alpha_1}, \ldots, 2^{\alpha_d}), \]

and the relational operators

\[ \alpha \leq \beta \iff \alpha_m \leq \beta_m, \forall m \]
\[ \alpha < \beta \iff \alpha \leq \beta \text{ and } \alpha \neq \beta. \]

Now, for a multi-index \( \mathbf{l} = (l_1, \ldots, l_d) \in \mathbb{N}_0^d \), which indicates the level of the mesh in a multivariate sense, we consider the standard rectangular grid \( \Omega_l \) with mesh size \( h_l := (2^{-l_1}, \ldots, 2^{-l_d}) \). We define the smallest size among all dimensions to be \( h = \min \{2^{-l_1}, \ldots, 2^{-l_d}\} \), an elementary cell \( I_l^j = \{ \mathbf{x} : x_m \in (2^{-l_m} j_m, 2^{-l_m} (j_m + 1)) \} \), and

\[ V^k_l = \{ \mathbf{v} : \mathbf{v}(\mathbf{x}) \in P^k(I^j_l), \ 0 \leq j \leq 2^l - 1 \}, \]

where \( P^k(I^j_l) \) denotes polynomials of degree up to \( k \) in each dimension on cell \( I^j_l \). The space \( V^k_l \) contains the traditional tensor-product piecewise polynomials used in the DG discretizations. Moreover, if we use equal refinement of size \( 2^{-N} \) in each direction, we denote the space to be \( V^k_N \), and it consists of \( (2^N(k + 1))^d \) degrees of freedom.

The foundation of sparse grids is to use the tensor product of the one-dimensional hierarchical decomposition, and only chooses the most relevant bases to guarantee suitable approximation properties. To illustrate the main ideas, we introduce

\[ W^k_l = W^k_{l_1,x_1} \times W^k_{l_2,x_2} \cdots \times W^k_{l_d,x_d}, \]

where \( W^k_{l_m,x_m} \) corresponds to the space \( W^k_{l_m} \) defined in the \( m \)-th dimension as defined in the previous subsection. The number of degrees of freedom associated with \( W^k_l \) is

\[ \dim(W^k_l) = \prod_{m=1}^d \dim(W^k_{l_m}). \]

Based on the one-dimensional hierarchical decomposition, it is easy to see

\[ V^k_l = V^k_{l_1,x_1} \times V^k_{l_2,x_2} \cdots \times V^k_{l_d,x_d} = \bigoplus_{j_1 \leq l_1, \ldots, j_d \leq l_d} W^k_j, \]

and

\[ V^k_N = V^k_{N,x_1} \times V^k_{N,x_2} \cdots \times V^k_{N,x_d} = \bigoplus_{|\mathbf{l}|_\infty \leq N} W^k_{\mathbf{l}}. \]

The basis functions for \( W^k_l \) can be defined by a tensor product

\[ v^j_{l,1}(\mathbf{x}) := \prod_{m=1}^d v^j_{i_m,l_m}(x_m), \quad j_m = 0, \ldots, \max(0, 2^{l_m-1} - 1); \ i_m = 1, \ldots, k + 1. \]
They form a set of orthonormal basis due to the property of the one-dimensional bases.

Now, we are ready to introduce the sparse finite element approximation space. In particular, we define

\[ \hat{V}_N^k := \bigoplus_{|\mathbf{l}|_1 \leq N} W^{k}_1. \]

This definition is motivated by continuous finite element space on sparse grid [15]. Instead of considering the standard piecewise polynomial space \( V_N^k \), which has exponential dependence on the dimension \( d \), we shall use its subspace \( \hat{V}_N^k \). This space has good approximation results (see Section 2.3 for details) with significantly reduced degrees of freedom. We remark that the key in the construction lies in the choice of condition for \( |\mathbf{l}|_1 \leq N \).

As demonstrated in [15], other conditions are also possible to realize dimension reduction with aims of optimizing various types of approximation results. We defer the numerical study for the comparison of several different spaces to Section 2.4.

**Remark 2.2** We mentioned in the previous subsection that there are different ways to construct the increment space \( W_n^k \). However, the choice will not affect the definition of \( \hat{V}_N^k \). This is because

\[ \bigoplus_{|\mathbf{l}|_1 \leq N} W^{k}_1 = \bigoplus_{|\mathbf{l}|_1 \leq N} V^k_1 = \bigoplus_{|\mathbf{l}|_1 \leq N} W^k_1, \]

for any space \( W^k_1 \) constructed from one dimensional increment space \( W_n^k \) satisfying \( V_{n-1}^k \oplus W_n^k = V_n^k \).

The next lemma will give a count of dimensions for the space \( \hat{V}_N^k \).

**Lemma 2.3** The dimension of \( \hat{V}_N^k \) is given by

\[
\dim(\hat{V}_N^k) = (k+1)^d \left\{ \sum_{m=0}^{d-1} \binom{d}{m} \left( (-1)^{d-m} + 2^{N+m-d+1} \sum_{n=0}^{d-m-1} \binom{N}{n} \cdot (-2)^{d-m-1-n} \right) \right\} + 1.
\]

Suppose there is an upper bound on the dimension \( d \leq d_0 \), then there exist constants \( c_{d_0}, C_{d_0} \) depending only on \( d_0 \), such that

\[
c_{d_0}(k+1)^d 2^N N^{d-1} \leq \dim(\hat{V}_N^k) \leq C_{d_0}(k+1)^d 2^N N^{d-1}.
\]

**Proof:** Due to the distinctiveness of the zero-th level in a mesh, we need to distinguish the zero-th level from other levels in the proof. Therefore, for each multi-index \( \mathbf{l} \), we define the set of the dimensions with mesh level 0 as \( \mathbf{l}^0 = \{i| l_i = 0, i = 1, \ldots, d\} \) and the number of such dimensions as

\[ |\mathbf{l}|_0 := \# \text{ in } \mathbf{l}^0. \]

Then

\[
\dim(\hat{V}_N^k) = \dim\left( \bigoplus_{|\mathbf{l}|_1 \leq N} W^{k}_1 \right)
\]

\[ = \sum_{m=0}^{d} \dim\left( \bigoplus_{|\mathbf{l}|_0 = m, |\mathbf{l}|_1 \leq N} W^{k}_1 \right). \]

8
We will discuss two cases based on the value of $|l|_0$.

**Case 1.** $0 \leq |l|_0 = m \leq d - 1$, i.e., there are $m$ dimensions of level zero from the $d$ dimensions of the multi-index $l$. Clearly,

$$\dim\left( \bigoplus_{|l|_0 = m, |l|_1 \leq N} W^k_l \right) = \binom{d}{m} \dim\left( \bigoplus_{t_1 = 0, 1 \leq t \leq m; t_1 > 0, t > m} W^k_{|l|_1 = N} \right).$$

Since there are $d - m$ dimensions that have meshes of level no less than one, we always have $|l|_1 \geq d - m$. Define $e_m = (0, \ldots, 0, 1, \ldots, 1)$ to be a vector in $\mathbb{N}^d_0$ whose first $m$ dimensions are 0, and the rest $d - m$ dimensions are 1. Then, by Lemma 3.6 in [15],

$$\dim\left( \bigoplus_{l_t = 0, 1 \leq t \leq m; l_t > 0, t > m} W^k_l \right) = (k + 1)^d \sum_{n=d-m}^{N} 2^{n-(d-m)} \sum_{l_t = 0, 1 \leq t \leq m; l_t > 0, t > m} 1$$

$$= (k + 1)^d \sum_{n=d-m}^{N} 2^{n-(d-m)} \binom{n-1}{d-m-1}$$

$$= (k + 1)^d \sum_{n=0}^{N+m-d} 2^n \binom{n + (d - m) - 1}{d - m - 1}$$

$$= (k + 1)^d \left( (-1)^{d-m} + 2^{N+m-d+1} \sum_{n=0}^{d-m-1} \binom{N}{n} \cdot (-2)^{d-m-1-n} \right).$$

**Case 2.** $|l|_0 = d$ means $l = 0$. Therefore,

$$\dim\left( \bigoplus_{|l|_0 = d, |l|_1 \leq N} W^k_l \right) = \dim(W^k_0) = (k + 1)^d.$$

Finally, we combine both cases, and arrive at

$$\dim(\hat{V}_N^k) = \sum_{m=0}^{d} \dim\left( \bigoplus_{|l|_0 = m, |l|_1 \leq N} W^k_l \right)$$

$$= (k + 1)^d \left\{ \sum_{m=0}^{d-1} \binom{d}{m} \left( (-1)^{d-m} + 2^{N+m-d+1} \sum_{n=0}^{d-m-1} \binom{N}{n} \cdot (-2)^{d-m-1-n} \right) + 1 \right\}.$$
We notice that
\[
\sum_{m=0}^{d-1} \binom{d}{m} 2^{N-m-d+1} \sum_{n=0}^{d-m-1} \binom{N}{n} \cdot (-2)^{d-m-1-n} \\
\leq \sum_{m=0}^{d-1} \binom{d}{m} 2^{N-m-d+1} C_{d_0} N^{d-m-1} \\
\leq C_{d_0} 2^{N-d+1} N^{d-1} \sum_{m=0}^{d} \binom{d}{m} 2^{m} N^{-m} \\
= C_{d_0} 2^{N} N^{d-1} (1 + \frac{2}{N})^d \leq C_{d_0} 2^{N} N^{d-1},
\]
where we use \(C_{d_0}, c_{d_0}\) to denote generic constants that depend only on \(d_0\), not on \(d, k, N\). They may have different values in each occurrence throughout the proof.

Similarly,
\[
dim(\hat{V}_k^N) \geq \dim\left( \bigoplus_{|l|=0,|l| \leq N} W_1^k \right) = (k+1)^d \left( (-1)^d + 2^{N-d+1} \sum_{n=0}^{d-1} \binom{N}{n} \cdot (-2)^{d-1-n} \right) \\
\geq (k+1)^d \left( -1 + c_{d_0} 2^{N-d+1} N^{d-1} \right) \geq c_{d_0} (k+1)^d 2^N N^{d-1}.
\]

In summary, there exist constants \(c_{d_0}, C_{d_0}\), such that
\[
c_{d_0} (k+1)^d 2^N N^{d-1} \leq \dim(\hat{V}_k^N) \leq C_{d_0} (k+1)^d 2^N N^{d-1},
\]
and we are done.

This lemma implies that, upon mesh refinement, the degrees of freedom for the sparse finite element space will grow in the order of \(h^{-1} |\log_2 h|^{d-1}\) instead of \(h^{-d}\) for the traditional piecewise polynomial space. This translates into a significant reduction in computational cost when \(d\) is large. The next subsection will verify approximation property of the space \(\hat{V}_N^k\).

## 2.3 Approximation Results

Given any one-dimensional projection operator \(P_n^k\) and its increment operator \(Q_n^k\), we can naturally define a projection from \(H^1(\Omega)\) to \(\hat{V}_N^k\) as,
\[
P_N^k := \sum_{|l| \leq N} Q_{l_{1,x_1}}^k \otimes \cdots \otimes Q_{l_{d,x_d}}^k,
\]
where \(Q_{l_{m,x_m}}^k\) denotes the operator \(Q_{l_{m}}^k\) in the \(m\)-th dimension. In [18], continuous sparse finite element space is used with streamline diffusion method to solve transport-dominated diffusion problem. The finite element space considered is \(\hat{V}_N^k := \hat{V}_N^k \cap C^0(\Omega)\) for \(k \geq 1\). The approximation properties for projector defined in (5) in \(L^2(\Omega), H^1(\Omega), H^2(\Omega_N)\) norms are
obtained when $P_k^n$ is a univariate projector onto $V^k_n \cap C^0([0,1])$ satisfying (3). Because $\tilde{V}_N^{c,k}$ is a subset of $\tilde{V}_N^k$, we can directly use the results in [48] and obtain an estimate of the projection error for $\tilde{P}_N^k$.

We introduce some notations about the seminorm of a function’s mixed derivatives. For any set $I = \{i_1, \ldots, i_r\} \subset \{1, \ldots, d\}$ with $|I| = r$, we define $I^c$ to be the complement set of $I$ in $\{1, \ldots, d\}$. For non-negative integers $\alpha, \beta$ and set $I$, we define the seminorm

\[
|v|_{H^\alpha,\beta,I(\Omega)} := \sum_{0 \leq \alpha_1 \leq \alpha} \cdots \sum_{0 \leq \alpha_r \leq \alpha} \sum_{0 \leq \beta_1 \leq \beta} \cdots \sum_{0 \leq \beta_s \leq \beta} \left\| \left( \frac{\partial^{\alpha_1}}{\partial x_1^{\alpha_1}} \cdots \frac{\partial^{\alpha_r}}{\partial x_r^{\alpha_r}} \right) \left( \frac{\partial^{\beta_1}}{\partial x_1^{\beta_1}} \cdots \frac{\partial^{\beta_s}}{\partial x_1^{\beta_s}} \right) v \right\|_{L^2(\Omega)},
\]

and

\[
|v|_{H^{s+1}(\Omega)} := \max_{s \in \{0,1\}} \max_{1 \leq r \leq d} \left( \max_{|I|=r} |v|_{H^{s+1,I}(\Omega)} \right).
\]

We recall the following results in [48] about the approximation properties in $L^2(\Omega)$, $H^1(\Omega)$ and $H^2(\Omega)$ norm.

**Theorem 2.4** Let $P_N^k$ defined in (5) be constructed from $P_n^k$ which is a univariate projector onto $V_n^k \cap C^0([0,1])$ satisfying (3), then for $k \geq 1$, any $1 \leq t \leq \min\{p,k\}$, there exist constant $c_{k,t}$, $\kappa_0(k,t,N)$, $\kappa_1(k,t,N) > 0$, such that for any $v \in H^{s+1}(\Omega)$, $N \geq 1$, $d \geq 2$, we have

\[
|P_N^k v - v|_{H^s(\Omega)} = |P_N^k v - v|_{H^s(\Omega)} \leq c_{k,t} d^{1+s/2} \kappa_s(k,t,N) d^{-1+s} 2^{-N(t+1-s)} |v|_{H^{t+1}(\Omega)},
\]

for $s = 0, 1$ ($L^2$ norm and $H^1$ seminorm), and

\[
|P_N^k v - v|_{H^2(\Omega)} \leq \begin{cases} c_{k,t} \left( d^{3/2} \kappa_1(k,t,N) d + d^2 \kappa_0(k,t,N) d^{-1} 2^{-N} \right) 2^{-N(t-1)} |v|_{H^{t+1}(\Omega)}, & k \geq 2 \\
2 \tilde{c}_{k,0,t} + c_{k,0,0}, & k = 1,
\end{cases}
\]

where

\[
\kappa_s(k,t,N) = \begin{cases} \tilde{c}_{k,0,t} (N+1) e^{1/(N+1)} + c_{k,0,0}, & s = 0 \\
2 \tilde{c}_{k,0,t} + c_{k,0,0}, & s = 1,
\end{cases}
\]

and $\tilde{c}_{k,0,t}, c_{k,0,0}$ are defined in [3] and [4]. Moreover, for $s = 0$, if

\[
\tilde{c}_{k,0,t} 2^{t+1} / (2^{t+1} - 1) + c_{k,0,0} < 1,
\]

there exists a positive constant $c_{t,k}$, such that $\kappa(k,t,s,N) < 1$ for all $N \geq 1$, $d \geq 2$ with $N + 1 \leq c_{t,k}(d-1)$.

This theorem implies a convergence rate of $O(h^{k+1})$ up to the polylogarithmic term $|\log_2 h|^{d-1}$ in the $L^2$ norm, which is comparable with the traditional full grid approach when the function $v$ retains enough smoothness (we actually do require higher regularity of the function $v$ when compared with standard piecewise polynomial spaces). This estimate serves as the foundation
in the error estimates of IPDG method in the energy norm. We remark that when switching the projection operator (say $L^2$ projection or other projectors on to $\hat{V}_N^k$) the error bound may change. However, our estimates in Section 3.2 do not require any particular property from the projection. Therefore, it suffices for us to use this theorem directly from [48]. In future work, we will establish convergence property of different projections onto $\tilde{V}_N^k$, for $k \geq 0$. This will be essential for error estimates for broader definitions of DG methods for other types of equations.

### 2.4 Approximations from Various Sparse Discontinuous Finite Element Spaces: A Numerical Investigation

In this subsection, we investigate the approximation properties of three sparse finite element spaces from a numerical perspective. As one can imagine, there is an intricate relation between the number of bases used with the approximation properties of the spaces. Indeed, the choice adopted in Section 2.2 is not unique in sparse grids literature. Ideally, how to choose the “best” bases is an optimization problem of cost/benefit ratios [31], and the ultimate strategy may be an adaptive algorithm. Our preliminary study in this subsection compares three intuitive choices of spaces, including $\hat{V}_N^k$ defined in the previous subsections, and

$$\hat{V}_N^k := \bigoplus_{|l|_1 \leq N + d - 1} \hat{W}_l^k,$$

which is a slightly larger space. $\tilde{V}_N^k$ contains the sparse continuous piecewise linear space in [15] when $k \geq 1$. Moreover, by a similar argument as in the proof of Lemma 2.3 its degrees of freedom, though slightly larger, are also of the order $h^{-1}\lceil \log_2 h \rceil^{d-1}$.

The other space we consider retains not only sparsity with respect to $h$, but also with respect to the degree of polynomials (we call this $p$-sparsity). If we introduce

$$\tilde{W}_l^k = \bigoplus_{|k|_l \leq k} W_l^k,$$

with $k = (k_1, \cdots, k_d)$, the new sparse space can be defined as

$$\hat{V}_N^k := \bigoplus_{|l|_1 \leq N} \tilde{W}_l^k.$$

It is clear that

$$\hat{V}_N^k \subset \tilde{V}_N^k \subset \hat{V}_N^k.$$

A similar argument of Lemma 2.3 gives,

**Lemma 2.5** The dimension of $\tilde{V}_N^k$ is

$$\dim(\tilde{V}_N^k) = \binom{k + d}{d} \left\{ \sum_{m=0}^{d-1} \binom{d}{m} (-1)^{d-m} + 2^{N+m-d+1} \sum_{n=0}^{d-m-1} \binom{N}{n} \cdot (-2)^{d-m-1-n} \right\} + 1.$$
Suppose there is an upper bound on the dimension \( d \leq d_0 \), then there exist constants \( c_{d_0}, C_{d_0} \) depending only on \( d_0 \), such that

\[
c_{d_0} \left( \frac{k + d}{d} \right) 2^N N^{d-1} \leq \dim(\hat{\mathcal{V}}^k_N) \leq C_{d_0} \left( \frac{k + d}{d} \right) 2^N N^{d-1}.
\]

Note that, when \( k \) and \( d \) are large, \( \dim(\hat{\mathcal{V}}^k_N) \) can be significantly smaller than \( \dim(\hat{\mathcal{V}}^k_N) \) and \( \dim(\tilde{\mathcal{V}}^k_N) \). As for the implementation of the space \( \hat{\mathcal{V}}^k_N \), we can no longer use the orthogonal hierarchical bases in Section 2.1 to represent functions in \( \hat{\mathcal{V}}^k_N \), since the vanishing-moment functions \( f_i \), which are used to construct the orthogonal hierarchical bases, have the same degrees. Instead, we can adopt another set of non-orthogonal hierarchical basis functions defined as follows. We first construct the bases for \( W^k_n \). Again, the case of \( n = 0 \) is trivial. Similar to the orthogonal case, the bases for \( W^k_n \), \( n \geq 1 \) are

\[
\hat{v}_{i,n}^j(x) = 2^{(n-1)/2} \hat{f}_i(2^{n-1}x - j), \quad i = 1, \ldots, k + 1, \quad j = 0, \ldots, 2^n - 1.
\]

In summary, the basis functions in \( \hat{\mathcal{W}}_1^k \) (and \( \hat{\mathcal{V}}^k_N \)) are

\[
\hat{v}_{1,1}^j(x) := \prod_{m=1}^d v_{m,1,m}^j(x_m), \quad j_m = 0, \ldots, \max(0, 2^{l_m-1} - 1).
\]

This set of basis is no longer orthonormal in the \( L^2 \) sense, but a Gram-Schmidt algorithm can be adopted to achieve the purpose.

Ideally, we should be able to use detailed analysis to compare the approximation results from the three spaces. However, for simplicity of implementation, here we only provide a numerical comparison for the approximation of a smooth function

\[
u(x) = \exp \left( \prod_{m=1}^d x_i \right), \quad x \in [0, 1]^d,
\]

by the standard \( L^2 \) projections: \( \hat{P}_n^k, \tilde{P}_n^k \), and \( \hat{\mathcal{P}}_n^k \) onto \( \hat{\mathcal{V}}^k_N, \tilde{\mathcal{V}}^k_N, \) and \( \tilde{\mathcal{V}}^k_N \), respectively. We measure various norms of the projection errors and the degrees of freedom for each space to find the best balance between accuracy and efficiency among the three choices.
In Tables 1-2, we report the projection errors $e_1 = \hat{P}_n u - u$, $e_2 = \tilde{P}_n u - u$ and $e_3 = \hat{\hat{P}}_n u - u$ in $L^1$, $L^2$, $L^\infty$, and $H^1$ norms and the associated orders of accuracy for $k = 2$, $d = 2, 3$. The detailed computational procedures as well as errors for other values of $d$ and $k$ are reported in [55]. For all three spaces, the degrees of freedom are all significantly less than $(k + 1)^d 2^{N_d}$, which is the degree of freedom for the full grid approximation. For space $\hat{V}_N^k$, $(k + 1)$-th order of accuracy is clearly observed for the $L^1$ and $L^2$ errors, and $k$-th order of accuracy is observed for the $H^1$ error, while slight reduction of accuracy is observed for the $L^\infty$ error. For space $\hat{\hat{V}}_N^k$, $k$-th order of accuracy is observed for the $H^1$ error and slight reduction of accuracy is observed for $L^1$ and $L^2$ errors. However, we do observe about half-order to one order reduction of accuracy for the $L^\infty$ error. We remark that the magnitude of errors computed by space $\hat{V}_N^k$ is larger than that by space $\hat{\hat{V}}_N^k$ for a fixed $N$. The apparent reason is that the degrees of freedom of $\hat{V}_N^k$ are smaller than $\hat{\hat{V}}_N^k$. However, when the degrees of freedom are comparable for the two spaces, the magnitude of errors computed by space $\hat{V}_N^k$ is smaller than $\hat{\hat{V}}_N^k$. Therefore, $\hat{V}_N^k$ is preferred if the computational efficiency is concerned. For $\hat{\hat{V}}_N^k$, which has the least degrees of freedom among the three sparse spaces, severe reduction of accuracy is observed for all error norms. Moreover, the magnitude of errors is significantly larger than that by space $\hat{V}_N^k$ or $\hat{\hat{V}}_N^k$ with comparable degrees of freedom.

In summary, based on the discussion, we will adopt space $\hat{V}_N^k$ in the computation for elliptic equations in the next section. A further reduction in computational cost is possible by finding the optimal subset of $\hat{V}_N^k$ by adaptive algorithms. We do not pursue this direction in this paper, and leave it to future study.

3 IPDG Method on Sparse Grids for Elliptic Equations

In this section, we solve the second order linear elliptic boundary value problem (1) by IPDG methods with the sparse finite element space $\hat{V}_N^k$. We will first formulate the scheme and discuss its implementation details, and then perform a priori error analysis.

3.1 Formulation of the Scheme

First, we introduce some basic notations about jumps and averages for piecewise functions defined on a grid $\Omega_N$. Let $\Gamma := \bigcup_{T \in \Omega_N} \partial T$ be the union of the boundaries for all the elements in $\Omega_N$ and $S(\Gamma) := \Pi_{T \in \Omega_N} L^2(\partial T)$ be the set of $L^2$ functions defined on $\Gamma$. For any $q \in S(\Gamma)$ and $\hat{q} \in [S(\Gamma)]^d$, we define their averages $\{q\}, \{\hat{q}\}$ and jumps $[q], [\hat{q}]$ on the interior edges as follows. Suppose $e$ is an interior edge shared by elements $T_+$ and $T_-$, we define the unit normal vectors $n^+$ and $n^-$ on $e$ pointing exterior to $T_+$ and $T_-$, and then

$$[q] = q^- n^- + q^+ n^+, \quad \{q\} = \frac{1}{2} (q^- + q^+),$$

$$[\hat{q}] = \hat{q}^- \cdot n^- + \hat{q}^+ \cdot n^+, \quad \{\hat{q}\} = \frac{1}{2} (\hat{q}^- + \hat{q}^+).$$
Table 1: Projection errors and orders of accuracy. SGDOF denotes the degrees of freedom of the sparse approximation space in use. FGDOF denotes the degrees of freedom of the full grid approximation space and is equal to $2^{Nd}(k + 1)^d$. $d = 2$. $k = 2$.

If $e$ is a boundary edge, then we let
\[ [q] = q n, \quad \{q\} = q, \]
where $n$ is the outward unit normal.

Now we are ready to formulate the IPDG scheme for (1). We look for $u_h \in \hat{V}_N^k$, such that
\[ B(u_h, v) = L(v), \quad \forall v \in \hat{V}_N^k \tag{6} \]
where
\[ B(w, v) = \int_\Omega \mathbf{K} \nabla w \cdot \nabla v \, dx - \sum_{e \in \Gamma} \int_e \{\mathbf{K} \nabla w\} \cdot [v] \, ds \]
\[ - \sum_{e \in \Gamma} \int_e \{\mathbf{K} \nabla v\} \cdot [w] \, ds + \sum_{e \in \Gamma} \frac{\sigma}{h_e} \int_e [w] \cdot [v] \, ds, \tag{7} \]
and
\[ L(v) = \int_\Omega f v \, dx - \int_{\partial \Omega} \left( \mathbf{K} \nabla v \cdot n + \frac{\sigma}{h} v \right) g \, ds, \tag{8} \]
where $\sigma$ is a positive penalty parameter, $h = 2^{-N}$ is the uniform mesh size in each dimension. The IP methods developed in [56, 5] are popular methods for elliptic equations, but usually with standard piecewise polynomial space. Here, by using the sparse finite element space, we can achieve a significant reduction in the size of the linear algebraic system (6) especially when $d$ is large.

Several issues still have to be addressed to ensure real computational gains in implementation. First of all, it is obvious that we need efficient algorithms to evaluate $L(v)$ when $v$ is taken to be the basis functions $v_{i1}^d(x)$ in $\hat{V}_N^k$. A standard integration scheme will incur computational complexity with exponential dependence on $d$. To avoid this, in our algorithm, we take full advantage of numerical integration on sparse grids developed in the literature [51, 27]. In particular, for each basis $v_{i1}^d(x)$, its domain of dependence consists of $2^d$ smooth patches. Therefore, when evaluating $\int_\Omega f v_{i1}^d \, dx$, we first divide this integral into $2^d$ parts accordingly, and then for each patch, we implement a sparse grid integration with Gauss quadrature, and the number of levels employed in this calculation is taken as $(I_{\text{quad}} - ||l||1/2)$, where $I_{\text{quad}}$ is a fixed integer chosen large enough to guarantee sufficient accuracy. The evaluation of $\int_{\partial \Omega} (\mathbf{K} \nabla v \cdot n + \frac{\sigma}{h} v) g \, ds$ can be performed in a similar fashion.

Another important factor when we assemble the linear system is the so-called unidirectional principle [13]. To demonstrate the main ideas, we can see that evaluating $\int_\Omega \phi(x) \, dx$ with $\phi(x) = \phi_1(x_1) \ldots \phi_d(x_d)$ is equivalent to multiplication of one-dimensional integrals $\int_{[0,1]} \phi_1 \, dx_1 \cdots \int_{[0,1]} \phi_d \, dx_d$. Therefore, computing $\int_\Omega f v_{i1}^d \, dx$ when $f(x)$ is separable, i.e. $f(x) = f_1(x_1) \ldots f_d(x_d)$ or when $f(x)$ is a sum of separable functions is straightforward, because we only need some small overhead to compute one-dimensional integrals and assemble them to obtain the multi-dimensional integrations.
The same discussion holds true for the computation of the bilinear term $B(u_h, v)$. For example, if we use a direct method, we need to evaluate $B(w, v)$ for $(w, v)$ being all possible basis functions in $\hat{V}_N^k$. From the definition of $B(w, v)$, each matrix element will involve four multi-dimensional integrations. If $K$ is separable (in particular, when $K$ is a constant function), due to the unidirectional principle, the matrices can be assembled fast. When $K$ is a general function, we need to compute true high dimensional integrals. This difficulty is identified as one of the main challenging tasks for computing PDEs on sparse grids, see e.g. [14, 1]. In this case, we can either use the sparse grid integration procedure mentioned above or by a computational procedure outlined as follows. Assume $K$ to be a smooth function, then we can find $K_h = \hat{P}_N^{2k}K$ as the $L^2$ projection of $K$ onto the sparse finite element space $\hat{V}_N^{2k}$, and use $K_h$ in place of $K$ in the scheme. Notice that $K_h$ is a sum of separable functions, therefore the computation of the bilinear term is accelerated as the unidirectional case. The reason we use a higher order sparse finite element for projection of $K_h$ is to obtain exact evaluation of the volume integral $\int_\Omega K \nabla u \cdot \nabla v \, dx$. However, this process does change the values of two other terms up to approximation error of $K_h - K$. Another aspect we did not explore is the efficient solver for the linear algebraic system. In the literature, iterative methods have been proposed based on the semi-coarsening approach and its sparse grid extensions [42, 43, 29, 34, 33, 46, 12]. We leave those interesting implementation aspects to future study.

### 3.2 Error Analysis

This section contains error estimates of the IPDG method on sparse grids. Following [5], we define the energy norm of a function $v \in H^2(\Omega_N)$ by

$$|||v|||^2 := \sum_{T \in \Omega_N} \int_T |\nabla v|^2 \, dx + \sum_{e \in \Gamma} h \int_e \left\{ \frac{\partial v}{\partial n} \right\}^2 ds + \sum_{e \in \Gamma_1} \frac{1}{h} \int_e [v]^2 ds.$$  

We review some basic properties of the bilinear operator $B(\cdot, \cdot)$.

**Lemma 3.1 (Orthogonality)** Let $u$ be the exact solution to (1), and $u_h$ be the numerical solution to (6), then

$$B(u - u_h, v) = 0, \quad \forall v \in \hat{V}_N^k.$$  

**Proof:** Using integration by parts, we can easily show $B(u, v) = 0, \forall v \in \hat{V}_N^k$. The Galerkin orthogonality immediately follows. \qed

**Lemma 3.2 (Boundedness**[5, 6]) **There exists a positive constant $C_b$, depending only on $K_1, \sigma$, such that**

$$B(w, v) \leq C_b |||w||| \cdot |||v|||, \quad \forall w, v \in H^2(\Omega_N).$$

**Lemma 3.3 (Stability**[5, 6]) **When $\sigma$ is taken large enough, there exists a positive constant $C_s$ depending only on $K_0$, such that**

$$B(v, v) \geq C_s |||v|||^2, \quad \forall v \in \hat{V}_N^k.$$  

18
\textbf{Theorem 3.4} Let $u$ be the exact solution to (1), and $u_h$ be the numerical solution to (6). For $k \geq 1$, $u \in H^{p+1}(\Omega)$, $1 \leq t \leq \min\{p,k\}$, $N \geq 1$, $d \geq 2$, we have

$$|||u - u_h||| \leq \left(1 + \frac{C_b}{C_s}\right) \sqrt{C_d C_s} 2^{-N} ||u||_{H^{p+1}(\Omega)}.$$ 

where $C_d$ is a constant that depends on $d$ linearly. $C_b, C_s$ are defined in Lemmas 3.2 and 3.3.

$$C^* = \max\left(\sqrt{d^2 \kappa_0^2 + 3d^3 \kappa_1^2 + 2d^4 \kappa_0^2 + 2d + 2d^4 \kappa_0^2}, \sqrt{d^2 \kappa_0^2 + 3d^3 \kappa_1^2 + 2d^4 \kappa_0^2}\right),$$

where $\kappa = \kappa_s(k,t,N)$, $s = 0,1$ and $C_{k,t}$ are defined in Theorem 2.4.

\textbf{Proof:} Choose any function $u_I \in \tilde{V}^k_N$, then we decompose the error into $e = u - u_h = (u - u_I) + (u_I - u_h)$. By Céa’s lemma, using Lemma 3.1, 3.2 and 3.3.

$$C_s||u_I - u_h||^2 \leq B_h(u_I - u, u_I - u_h) = B_h(u_I - u, u_I - u_h) \leq C_b||u - u_I|| \cdot ||u_I - u_h||.$$ 

Therefore, $||u_I - u_h|| \leq \frac{C_b}{C_s} ||u - u_I||$, and

$$|||e||| \leq |||u_I - u_h||| + ||u - u_I|| \leq \left(1 + \frac{C_b}{C_s}\right) |||u - u_I|||.$$ 

We have

$$|||e||| \leq \left(1 + \frac{C_b}{C_s}\right) \inf_{u_I \in \tilde{V}^k_N} |||u - u_I||| \leq \left(1 + \frac{C_b}{C_s}\right) |||u - \tilde{P}_N^k u|||,$$

where the projection operator $\tilde{P}_N^k$ has been specified in Theorem 2.4.

Next, we need to bound the energy norm of $\eta := u - \tilde{P}_N^k u$. Recall that

$$|||\eta|||^2 = \sum_{T \in \Omega_N} \int_T |\nabla \eta|^2 \, dx + \sum_{e \in \Gamma} h \int_e \left\{ \frac{\partial \eta}{\partial n} \right\}^2 \, ds + \sum_{e \in \Gamma} \frac{1}{h} \int_e [\eta]^2 \, ds.$$ 

The first term in the summation is

$$\sum_{T \in \Omega_N} \int_T |\nabla \eta|^2 \, dx = ||\eta||_{H^1(\Omega_N)}^2.$$ 

To bound the second and third terms, we use the trace inequalities [5]:

$$||\phi||^2_{L^2(\partial T)} \leq C_d \left( \frac{1}{h} ||\phi||^2_{L^2(T)} + h ||\phi||^2_{H^1(T)} \right), \quad \forall \phi \in H^1(T)$$

$$\left| \frac{\partial \phi}{\partial n} \right|_{L^2(\partial T)} \leq C_d \left( \frac{1}{h} ||\phi||^2_{H^1(T)} + h ||\phi||^2_{H^2(T)} \right), \quad \forall \phi \in H^2(T)$$

19
where $C_d$ is a generic constant that depends on $d$ linearly. It may have different values in each occurrence in the proof. Sum over all the elements, we get

$$
\sum_{e \in \Gamma} h \int_{e} \left( \frac{\partial \eta}{\partial n} \right)^2 \, ds \leq C_d \left( \| \eta \|_{H^1(\Omega_N)}^2 + h^2 \| \eta \|_{H^2(\Omega_N)}^2 \right)
$$

$$
\sum_{e \in \Gamma} \frac{1}{h} \int_{e} |\eta|^2 \, ds \leq C_d \left( \frac{1}{h^2} \| \eta \|_{L^2(\Omega_N)}^2 + |\eta|^2_{H^1(\Omega_N)} \right).
$$

In summary,

$$
\|\eta\| \leq C_d \left( \frac{1}{h^2} \| \eta \|_{L^2(\Omega_N)}^2 + |\eta|^2_{H^1(\Omega_N)} + h^2 \| \eta \|_{H^2(\Omega_N)}^2 \right).
$$

By Theorem 2.4

$$
\|\eta\|^2 \leq C_d \mathcal{L}_{k,t} \left( d^2 \kappa_0^{2d-2} + 3d^3 \kappa_1^{2d} + 2d^4 \kappa_0^{2d-2} - 2N \right) 2^{-2N} \| u \|_{H^{k+1}(\Omega)}, \quad k \geq 2
$$

$$
\|\eta\|^2 \leq C_d \mathcal{L}_{k,t} \left( d^2 \kappa_0^{2d-2} + 3d^3 \kappa_1^{2d} + 2d + 2d^4 \kappa_0^{2d-2} - 2N \right) 2^{-2N} \| u \|_{H^{k+1}(\Omega)}, \quad k = 1
$$

where we have used the shorthand notation $\kappa_s = \kappa_s(k, t, N)$, $s = 0, 1$. Let’s define

$$
C^* = \max \left( \sqrt{d^2 \kappa_0^{2d-2} + 3d^3 \kappa_1^{2d} + 2d^4 \kappa_0^{2d-2} - 2N}, \sqrt{d^2 \kappa_0^{2d-2} + 3d^3 \kappa_1^{2d} + 2d + 2d^4 \kappa_0^{2d-2} - 2N} \right).
$$

Then,

$$
\|\eta\| \leq \sqrt{C_d \mathcal{L}_{k,t}} C^* 2^{-Nt} \| u \|_{H^{k+1}(\Omega)}.
$$

Therefore, we have proved the error estimate in the energy norm

$$
\| e \| \leq \left( 1 + \frac{C_b}{C_s} \right) \sqrt{C_d \mathcal{L}_{k,t}} C^* 2^{-Nt} \| u \|_{H^{k+1}(\Omega)}.
$$

This theorem implies a convergence rate of $O(h^k)$ up to the polylogarithmic term $|\log_2 h|^{d-1}$ in the energy norm when $u$ is smooth enough. However, we do require more regularity of $u$ compared with IPDG methods using traditional piecewise polynomial space.

**Remark 3.5** Proving convergence in $L^2$ norm with the standard duality argument will encounter some difficulties in this framework. For example, let $\varphi$ be the solution to the adjoint problem

$$
- \nabla \cdot (K \nabla \varphi) = u - u_h \quad \text{on } \Omega, \quad \varphi = 0 \quad \text{on } \partial \Omega.
$$

Since $\Omega$ is convex, we have $\varphi \in H^2(\Omega)$, and $\| \varphi \|_{H^2(\Omega)} \leq C \| u - u_h \|_{L^2(\Omega)}$. From the adjoint consistency of the IP method, we get

$$
\| u - u_h \|_{L^2(\Omega)}^2 = B(u - u_h, \varphi).
$$

However, to proceed from here, we will need to define an interpolant of $\varphi$: $\varphi_1 \in \hat{V}_N$, and bound $\|\varphi - \varphi_1\|$. From our previous discussion, this will require a bound in $\|\varphi\|_{H^2(\Omega)}$. This is a stronger norm than the classical $H^2$ norm, and cannot be bounded by $\| u - u_h \|_{L^2(\Omega)}^2$. 

---

20
4 Numerical Results

In this section, we provide multi-dimensional numerical results to demonstrate the performance of our sparse grid IPDG scheme.

4.1 Two-dimensional Results

In this subsection, we gather computational results for two-dimensional case. The penalty constant in this subsection is chosen to be $\sigma = 10$ for $k = 1$, and $\sigma = 20$ for $k = 2$.

Example 4.1 We solve the following two-dimensional problem with constant coefficient on $\Omega = [0, 1]^2$.

\[
\begin{aligned}
-\Delta u &= 0, \quad x \in \Omega, \\
\displaystyle u = \sin(\pi x_1) \frac{\sinh(\pi x_2)}{\sinh(\pi)}, \quad x \in \partial \Omega,
\end{aligned}
\]  

(9)

for which the exact solution is $u = \sin(\pi x_1) \frac{\sinh(\pi x_2)}{\sinh(\pi)}$. We test the scheme with $k = 1$ and $k = 2$ on different levels of meshes. Numerical errors and orders of accuracy measured in $L^1$, $L^2$, $L^\infty$ and $H^1$ norms are listed in Table 3. We observe $k$-th order of accuracy for $H^1$ norm, close to $(k + 1)$-th order accuracy for $L^1$, $L^2$ norms and slightly less than $(k + 1)$-th order accuracy for the $L^\infty$ norm. The results agree with the error estimates performed in the previous section. The slight order reduction for $L^1$, $L^2$, and $H^1$ norms is similar to the one observed in Section 2.4.

In addition, we provide the sparsity patterns and the condition number of the stiffness matrices for $k = 1$ and $k = 2$ in Figure 1 and Table 4. From Table 4, the number of nonzero elements scales as $O(SGDOF^1.5)$, where $SGDOF$ is the number of degrees of freedom of the space used. This is a denser matrix than the one generated from traditional piecewise polynomial space, for which one element can only interact with itself and its immediate neighbors. For sparse grids, the basis functions in $\hat{V}_N^k$ are no longer locally defined due to the hierarchical structure. However, fixing any point $x$ in the domain $\Omega$, the number of bases with nonzero values at $x$ is a constant for each level. In this sense, the interaction between the bases is still limited when compared with a global approximation scheme.

Example 4.2 We solve the following two-dimensional problem with smooth variable coefficient on $\Omega = [0, 1]^2$.

\[
\begin{aligned}
-\nabla \cdot ((\sin(x_1 x_2) + 1) \nabla u) &= f, \quad x \in \Omega, \\
u &= 0, \quad x \in \partial \Omega.
\end{aligned}
\]

(10)

$f$ is a given function such that the exact solution is $u = \sin(\pi x_1) \sin(\pi x_2)$. As discussed in previous Section, when assembling the stiffness matrix, we first obtain the $L^2$ projection of coefficient $K$ in space $\hat{V}_N^{2k}$, then make use of the unidirectional principle to save computational
Table 3: Numerical errors and orders of accuracy for Example 4.1 computed by the space $\hat{V}_N^k$ with $k = 1, 2$ and indicated $N$.

| N | $L^1$ error | order | $L^2$ error | order | $L^\infty$ error | order | $H^1$ error | order |
|---|-------------|-------|-------------|-------|-----------------|-------|-------------|-------|
| $k = 1$ |
| 3 | 4.49E-03 | 6.97E-03 | 3.26E-02 | 1.77E-01 | |
| 4 | 1.18E-03 | 1.93E-03 | 1.85 | 9.71E-03 | 1.75 | 8.80E-02 | 1.01 |
| 5 | 3.03E-04 | 5.09E-04 | 1.92 | 3.19E-03 | 1.60 | 4.36E-02 | 1.01 |
| 6 | 7.68E-05 | 1.32E-04 | 1.98 | 9.68E-04 | 1.72 | 2.16E-02 | 1.01 |
| $k = 2$ |
| 3 | 9.52E-05 | 1.33E-04 | 5.74E-04 | 7.61E-03 | |
| 4 | 1.42E-05 | 2.75 | 2.03E-05 | 2.71 | 9.65E-05 | 2.57 | 1.91E-03 | 1.99 |
| 5 | 2.05E-06 | 2.79 | 3.02E-06 | 2.75 | 1.59E-05 | 2.60 | 4.78E-04 | 2.00 |
| 6 | 2.89E-07 | 2.83 | 4.36E-07 | 2.79 | 2.66E-06 | 2.58 | 1.19E-04 | 2.00 |

Table 4: Sparsity and condition number of the stiffness matrix. Example 4.1 computed by the space $\hat{V}_N^k$ with $k = 1, 2$. SGDOF is the number of degrees of freedom used for the sparse grid DG scheme. NNZ is the number of nonzero elements in the stiffness matrix. Order=$\log(\text{NNZ})/\log(\text{SGDOF})$.

| N | SGDOF | NNZ | Order | Condition Number |
|---|-------|-----|-------|------------------|
| $k = 1$ |
| 3 | 80 | 992 | 1.57 | 3.58E+02 |
| 4 | 192 | 3216 | 1.54 | 1.43E+03 |
| 5 | 448 | 9168 | 1.49 | 5.68E+03 |
| 6 | 1024 | 24144 | 1.45 | 2.26E+04 |
| $k = 2$ |
| 3 | 180 | 3456 | 1.57 | 1.40E+03 |
| 4 | 432 | 11124 | 1.54 | 5.49E+03 |
| 5 | 1008 | 31596 | 1.50 | 2.16E+04 |
| 6 | 2304 | 83028 | 1.46 | 8.58E+04 |
cost. The numerical results are provided in Table 5. The conclusion is very similar to the constant coefficient case Example 4.1. We observe \(k\)-th order of accuracy for \(H^1\) norm, close to \((k+1)\)-th order of accuracy for \(L^1, L^2\) norms and slightly less than \((k+1)\)-th order of accuracy for the \(L^{\infty}\) norm.

**Example 4.3** We solve the following two-dimensional problem with discontinuous coefficient on \(\Omega = [0,1]^2\).

\[
\begin{cases}
-\nabla \cdot ((\text{sign}((x_1 - 0.5)(x_2 - 0.5)) + 2) \nabla u) = f, & x \in \Omega, \\
u = 0, & x \in \partial \Omega.
\end{cases}
\tag{11}
\]

\(f\) is a given function such that the exact solution is \(u = \sin(\pi x_1) \sin(\pi x_2)\). In this example, the coefficient has four constant panels on \(\Omega\), but the solution itself is smooth. We want to use this example to demonstrate the performance of the proposed scheme when solving problems with discontinuous coefficient. We provide the numerical results with \(k = 1\) and \(k = 2\) in Table 6. Notice that in this example, the discontinuity of the coefficient is along the cell boundaries for all our computational grids, and the convergence rates are similar to the previous two examples.

### 4.2 Three-dimensional Results

In this subsection, we gather computational results for three-dimensional elliptic equations. The penalty constant in this subsection is chosen to be \(\sigma = 15\) for \(k = 1\), and \(\sigma = 30\) for \(k = 2\).
Table 5: Numerical errors and orders of accuracy for Example 4.2 computed by the space $V^k_N$ with $k = 1, 2$ and indicated $N$.

| $N$ | $L^1$ error | order | $L^2$ error | order | $L^\infty$ error | order | $H^1$ error | order |
|-----|--------------|-------|--------------|-------|------------------|-------|--------------|-------|
| 3   | 1.30E-02     |       | 1.65E-03     |       | 4.50E-02         |       | 3.37E-01     |       |

Example 4.4 We solve the following three-dimensional problem with constant coefficient on $\Omega = [0, 1]^3$.

$$\begin{cases} -\Delta u = 0, \\ u = \sin(\pi x_1) \sin(\pi x_2) \frac{\sinh(\sqrt{2}\pi x_3)}{\sinh(\sqrt{2}\pi)}, & x \in \Omega, \\ u = \sin(\pi x_1) \sin(\pi x_2) \sinh(\sqrt{2}\pi x_3) \sinh(\sqrt{2}\pi), & x \in \partial \Omega, \end{cases} \quad (12)$$

where the exact solution is $u = \sin(\pi x_1) \sin(\pi x_2) \frac{\sinh(\sqrt{2}\pi x_3)}{\sinh(\sqrt{2}\pi)}$. We provide the numerical results with $k = 1$ and $k = 2$ in Table 7. For this three-dimensional example, we obtain $k$-th order for the $H^1$ norm, and close to $(k + 1)$-th order for the $L^1$ and $L^2$ norm, but $L^\infty$ error seems to degrade to $(k + \frac{1}{2})$-th order. However, upon closer examination, similar behaviors have been observed in Section 2.4 for the $L^2$ projection error of a smooth function onto $\hat{V}_N^k$. The sparsity patterns of the stiffness matrices for $k = 1$ and $k = 2$ are reported in Figure 2 and Table 8. From Table 8 we can see the stiffness matrices scale less than the two-dimensional examples, i.e., the number of nonzero elements scales as $O(SGDOF^{1.4})$, where $SGDOF$ is the number of degrees of freedom of the space used.

Example 4.5 We solve the following three-dimensional problem with smooth variable coefficient on $\Omega = [0, 1]^3$.

$$\begin{cases} -\nabla \cdot ((\sin(x_1 x_2 x_3) + 1) \nabla u) = f, & x \in \Omega, \\ u = 0, & x \in \partial \Omega, \end{cases} \quad (13)$$

$f$ is a given function such that the exact solution is $u = \sin(\pi x_1) \sin(\pi x_2) \sin(\pi x_3)$. Again, for such a non-separable coefficient $K$, the $L^2$ projection onto space $\hat{V}_N^k$ is obtained and the unidirectional principle is applied when we assemble the stiffness matrix. We provide the
Table 8: Sparsity and condition number of the stiffness matrix. Example 4.4 computed by the space $\tilde{V}_N^k$ with $k = 1, 2$. SGDOF is the number of degrees of freedom used for the sparse grid DG scheme. NNZ is the number of nonzero elements in the stiffness matrix. Order=$\log(\text{NNZ})/\log(\text{SGDOF})$.

| 5  | 4.72E-06    | 2.61  | 6.06E-06    | 2.60  | 2.73E-05        | 2.58  | 7.54E-04    | 2.00  |
| 6  | 7.42E-07    | 2.67  | 9.58E-07    | 2.66  | 5.80E-06        | 2.23  | 1.88E-04    | 2.00  |

The conclusion of Example 4.4 holds here, including the comparable convergence rate and similar order reduction of the $L^1$, $L^2$, and $L^\infty$ errors.
4.3 Four-dimensional Results

In this subsection, we gather computational results for four-dimensional case. The penalty constant in this subsection is chosen to be \( \sigma = 30 \) for \( k = 1 \), and \( \sigma = 60 \) for \( k = 2 \).

**Example 4.6** We solve the following four-dimensional problem with constant variable coefficient on \( \Omega = [0,1]^4 \).

\[
\begin{aligned}
-\Delta u &= 0 & \quad & x \in \Omega, \\
u &= \sin(\pi x_1) \sin(\pi x_2) \sin(\pi x_3) \frac{\sinh(\sqrt{3}x_4)}{\sinh(\sqrt{3}\pi)} & \quad & x \in \partial \Omega \\
\end{aligned}
\]

(14)

where the exact solution is 
\( u = \sin(\pi x_1) \sin(\pi x_2) \sin(\pi x_3) \frac{\sinh(\sqrt{3}x_4)}{\sinh(\sqrt{3}\pi)} \).

We list numerical errors and orders in Table 10. For this four-dimensional example, we obtain \( k \)-th order for the \( H^1 \) norm, and close to \((k+\frac{1}{2})\)-th order for the \( L^1 \) and \( L^2 \) norms. The \( L^\infty \) error seems to fluctuate. However, we expect the order of accuracy in \( L^\infty \) norm to grow upon refinement. The numerical results when fixing two of the coordinates are plotted in Figure 3 for \( k = 1 \) and \( k = 2 \) when \( N = 4 \). The left and right figures are obtained with degrees of freedom equal to 3072 and 15552, respectively. We can see the higher order scheme offers a much more accurate solution than the lower order scheme, and this is also verified by Table 10. The sparsity patterns and condition number of the stiffness matrices for \( k = 1 \) and \( k = 2 \) are reported in Figure 4 and Table 11. From Table 11, we can see the stiffness matrices scale less than the two-dimensional and three-dimensional examples, i.e., the number of nonzero elements scales like \( O(SGDOF^{1.35}) \), where \( SGDOF \) is the degree of freedom of the space used.

![Figure 3](image.png)

(a) $k = 1$; (b) $k = 2$. $N = 4$. Plotted along $x_1 = 0.4930, x_2 = 0.4930$. 

28
Table 10: Numerical errors and orders of accuracy for Example 4.6 computed by the space $\hat{V}_N^k$ with $k = 1, 2$ and indicated $N$.

| $k = 1$ | $L^1$ error | order | $L^2$ error | order | $L^\infty$ error | order | $H^1$ error | order |
|---------|-------------|-------|-------------|-------|------------------|-------|-------------|-------|

| 5       | 3.68E-03   | 1.54   | 7.15E-03   | 1.54   | 9.33E-02   | 0.31   | 1.22E-01   | 0.96   |

| $k = 2$ | $L^1$ error | order | $L^2$ error | order | $L^\infty$ error | order | $H^1$ error | order |
|---------|-------------|-------|-------------|-------|------------------|-------|-------------|-------|
| 2       | 8.21E-04   | 1.34E-03 | 1.11E-02   | 4.20E-02 |
| 3       | 1.76E-04   | 2.22   | 2.79E-04   | 2.27   | 2.76E-03   | 2.00   | 1.20E-02   | 1.81   |
| 4       | 3.32E-05   | 2.40   | 5.39E-05   | 2.37   | 8.76E-04   | 1.66   | 3.18E-03   | 1.91   |

Table 11: Sparsity and condition number of the stiffness matrix. Example 4.6 computed by the space $\hat{V}_N^k$ with $k = 1, 2$. SGDOF is the number of degrees of freedom used for the sparse grid DG scheme. NNZ is the number of nonzero elements in the stiffness matrix. Order=\(\log(\text{NNZ}) / \log(\text{SGDOF})\).

| $k = 1$ | SGDOF | NNZ   | Order | Condition Number |
|---------|-------|-------|-------|------------------|
| 3       | 1008  | 12272 | 1.36  | 4.27E+02         |
| 4       | 3072  | 51712 | 1.35  | 2.26E+03         |
| 5       | 8832  | 187008| 1.34  | 9.27E+03         |

| $k = 2$ | SGDOF | NNZ   | Order | Condition Number |
|---------|-------|-------|-------|------------------|
| 2       | 1539  | 19683 | 1.35  | 7.40E+02         |
| 3       | 5103  | 102303| 1.35  | 2.62E+03         |
| 4       | 15552 | 420336| 1.34  | 9.72E+03         |

Figure 4: Example 4.6. The sparsity patterns of the matrices computed by the space $\hat{V}_N^k$ with (a) $k = 1$ and (b) $k = 2$. Each dot represents a non-zero element in the stiffness matrix.
Example 4.7 We solve the following four-dimensional problem with smooth variable coefficient on \( \Omega = [0, 1]^4 \).

\[
\begin{align*}
- \nabla \cdot ((\sin(x_1 x_2 x_3 x_4) + 1) \nabla u) &= f, \\
u &= 0,
\end{align*}
\]

(15)

\( f \) is a given function such that the exact solution is \( u = \sin(\pi x_1) \sin(\pi x_2) \sin(\pi x_3) \sin(\pi x_4) \).

We provide the numerical results with \( k = 1 \) and \( k = 2 \) in Table 12. The conclusion is similar to Example 4.6.

Table 12: Numerical errors and orders of accuracy for Example 4.7 computed by the space \( \hat{V}_N^k \) with \( k = 1, 2 \) and indicated \( N \).

| \( N \) | \( L^1 \) error | order | \( L^2 \) error | order | \( L^\infty \) error | order | \( H^1 \) error | order |
|------|-----------------|-------|-----------------|-------|-----------------|-------|-----------------|-------|
| \( k = 1 \) | | | | | | | | |
| 3 | 6.15E-02 | | | | | | | |
| 4 | 1.89E-02 | 1.70 | 2.63E-02 | 1.77 | 2.54E-01 | 0.21 | 3.20E-01 | 1.06 |
| 5 | 4.51E-03 | 2.07 | 6.80E-03 | 1.95 | 7.15E-02 | 1.83 | 1.45E-01 | 1.14 |
| \( k = 2 \) | | | | | | | | |
| 2 | 8.38E-04 | | | | | | | |
| 3 | 1.62E-04 | 2.37 | 2.13E-04 | 2.36 | 1.34E-03 | 1.38 | 1.01E-02 | 1.90 |
| 4 | 2.97E-05 | 2.44 | 3.91E-05 | 2.45 | 3.80E-04 | 1.82 | 2.57E-03 | 1.97 |
5 Conclusion

In this paper, we develop a sparse grid IPDG method for elliptic equations on a box shaped domain. The method features a sparse finite element space which scales as $O(h^{-1} \log_2 h^{d-1})$ for $d$-dimensional problems, translating into a significant cost reduction when $d$ is large. The traditional IPDG formulation can be readily used, and when combined with approximation results for the new space, equip the scheme with error estimate that is only slightly deteriorated in the energy norm. Numerical results in up to four dimensions are shown to validate the performance of the method. Future work includes the study of adaptive algorithm for less regular solutions, extension of the method to more general domains, and developing sparse grid DG methods for other types of high-dimensional equations.
