We propose a scheme to evaluate the amount of quantum discord and entanglement of formation for mixed states, and reveal their ordering relation via an intrinsic relationship between the two quantities distributed in different partners of the associated purification. This approach enables us to achieve analytical expressions of the two measures for a sort of quantum states, such as an arbitrary two-qubit density matrix reduced from pure three-qubit states and a class of rank-2 mixed states of 4 × 2 systems. Moreover, we apply the scheme to characterize fully the dynamical behavior of quantum correlations for the specified physical systems under decoherence.

Quantum correlation constitutes a fundamental resource for quantum information processing and it has been the subject of intensive studies in the last decades. The non-locality aspect of quantum correlations, termed as entanglement, was first singled out as the characteristic trait of quantum mechanics that is inaccessible to classical objects [1]. It is widely believed that entanglement constitutes the key ingredient leading to the power of quantum computation [2, 3]. Operationally, entangled states are those that cannot be prepared through local operations and classical communication between two parties [4]. In other words, they cannot be written as separable form: \( \rho_{AB} \neq \sum_k \rho_A^k \otimes \rho_B^k \). The amount of entanglement of \( \rho_{AB} \) shared in the two parties is usually defined by entanglement of formation (EoF) [5, 6], i.e., the minimal average entanglement of pure state ensembles to create \( \rho_{AB} \): \( E(\rho_{AB}) \equiv \min \sum_p E(\rho_k) \), where the minimum is taken over all possible decomposition \( \rho_{AB} = \sum_k \rho_k \langle \psi_k | \psi_k \rangle \), and \( E(\rho_k) \) is entropy entanglement of the pure state \( \langle \psi_k | \psi_k \rangle \) in the ensemble.

A different notion of measure, quantum discord \( Q_{AB} \), has also been proposed [6, 7] to characterize quantum correlations based on an information-theoretic measure of mutual information. Distinctly, quantum discord is figured out through quantifying the classicality and/or nonclassicality in the total mutual information \( I(\rho_{AB}) \equiv S(\rho_A) + S(\rho_B) − S(\rho_{AB}) \). It is defined as \( Q_{AB} \equiv I(\rho_{AB}) − J_{AB} \), the discrepancy between \( I(\rho_{AB}) \) and its classical counterpart \( J_{AB} \equiv S(\rho_B) − S(\rho_B|A) \), where \( S(\rho_B|A) \) is the conditional entropy, i.e., the minimal average entropy of \( B \), given measurements on \( A \) [cf. Eq. (1)]. For pure bipartite states \( \langle \psi_{AB} | \psi_{AB} \rangle \), discord is equal to the entropy entanglement, \( Q_{AB} = E(\langle \psi_{AB} | \psi_{AB} \rangle) \equiv -\text{tr}(\rho_A \log \rho_A) \), but for mixed states the discord is generally not identical to EoF except for particular cases. The conceptual difference of these two measures has motivated extensive studies recently, e.g., on their roles in performance of information processing [8, 9] and their relations to dynamics under decoherence [10]. On the other hand, quantitative evaluation of quantum discord involves an optimization procedure similar to that in the EoF. The absence of a tractable method to tackle it makes comparison of these two measures and relevant studies very obscure. Until now, the explicit expression of quantum discord has only been obtained for certain classes of two-qubit states [11, 12].

In this paper, we propose a scheme to evaluate the amount of quantum discord and EoF via an intrinsic relation between the two quantities distributed in the purification of given mixed states. The same relation of duality had been revealed by Koashi and Winter in a context to explore the monogamy nature of entanglement measures [12]. Here we demonstrate that the elicited trilateral relationship can be applied to quantify quantum discord and EoF and their ordering relation. In particularly, the scheme enables us to fully characterize the discord and EoF for certain quantum states, e.g., an arbitrary two-qubit state reduced from pure three-qubit states and a class of rank-2 mixed states of 4 × 2 systems. Additionally, we apply further the quantification scheme to describe the dynamical behavior of quantum correlations for specified systems under decoherence.

Conditional entropy versus entanglement of formation in purifications. Let us start with the conditional entropy

\[
S(\rho_B | A) \equiv \min_{\{ A_k \}} \sum_k p_k S(\rho^k_B | A_k),
\]

the central ingredient contained in the definition of the quantum discord. We discriminate two different operations of \( \{ A_k \} \), the von Neumann projective measurements \( \{ \Pi_k \equiv | k_A \rangle \langle k_A | : k = 1, \ldots, d \} \) and the generalized positive operator-valued measurements (POVMs) \( \{ A_k \} \) satisfying \( \sum_k A_k^\dagger A_k = I \). Their corresponding definitions of conditional entropy are denoted by \( S_I \) and \( S_{II} \), respectively. Accordingly, we have two kinds of definitions for quantum discord,

\[
Q_{AB}^{I,II} = S(\rho_A) + S_{I,II}(\rho_B | A) - S(\rho_{AB}).
\]
To proceed we invoke the so-called purification $|\Psi_{ABC}\rangle$ of $\rho_{AB}$, whose partial trace on the ancillary $C$ gives rise to $\text{tr}_C(|\Psi_{ABC}\rangle\langle\Psi_{ABC}|) = \rho_{AB}$. Suppose that $C$ has a dimension equal to the rank of $\rho_{AB}$, then all such purifications should be equivalent up to local unitary transformations on $C$. With the notion of $|\Psi_{ABC}\rangle$, each outcome of the orthogonal projective measurement $|k_A\rangle\langle k_A|$ will be associated with a relative state $|\psi_{BC}\rangle = \langle k_A|\Psi_{ABC}|\psi_{BC}\rangle/\sqrt{p_k}$, where $p_k$ is the probability of the $k$th outcome. The entropy of $B$ (same as that of $C$), conditioned to the $k$th outcome, is precisely captured by the entropy entanglement in $|\psi_{BC}\rangle$: $S(\rho_B |A_k) = E(|\psi_{BC}\rangle) = S(\rho^E_{BC} |A_k)$. Furthermore, in view that the set of relative states $(p_k, |\psi_{BC}\rangle)$ form actually an ensemble that realizes $\rho_{BC}$, namely, $\rho_{BC} = \sum_k p_k|\psi_{BC}\rangle\langle\psi_{BC}|$, we obtain

$$S_I(\rho_B |A) = \min_{\{A_k\}} \sum_k p_k E(|\psi_{BC}\rangle) = E(\rho_{BC}),$$

(3)

where $E(\rho_{BC})$ defines a $d$-component EoF, i.e., minimal average entanglement of $\rho_{BC}$ over ensemble decompositions with only $d$ components. In general there is $E(\rho_{BC}) \geq E(\rho_{BC})$ since the minimization in the definition of $E(\rho_{BC})$ is taken over all ensemble decompositions realizing $\rho_{BC}$ but the $d$-component ensemble decompositions via the outcome of projective measurements $\{\Pi_k\}$ on $A$ are only portion of them.

On the other hand, the outcome via the complete set of POVMs $\{A_k\}$ offers a distinct way to realize $\rho_{BC}$ in view that $\sum_k p_k A_k |\Psi_{ABC}\rangle\langle\Psi_{ABC}|A_k\rangle = \rho_{BC}$. Note that the ensemble generated here comprises also those of mixed states. It follows from the concavity property of von Neumann entropy that the minimum of the conditional entropy of Eq. (11) is always reached with ensembles of pure states [13]. Consequently, it happens that for the quantity $S_{II}(\rho_B |A)$ in which POVMs on $A$ are promised, there exists

$$S_{II}(\rho_B |A) = E(\rho_{BC}) = S_{II}(\rho_C |A).$$

(4)

To make clear that a POVM realizing the optimal ensemble with minimal average entanglement $E(\rho_{BC})$ can always be constructed, it is instructive to invoke the following fact: by including an external system $E$ with an arbitrary high dimension and performing joint unitary evolutions on $A$ and $E$, all ensembles of pure states reproducing $\rho_{BC}$ can be generated via the outcome $\{p_k, |\psi_{BC}\rangle\}$ associated with von Neumann measurements $\{|k\rangle_{AE}|\psi_{BC}\rangle\langle\psi_{BC}|\}$ on $A$ and $E$, where

$$|\psi_{BC}\rangle = \langle k_{AE}|U_{AE}(\Psi_{ABC}) \otimes |0_E\rangle)/\sqrt{p_k}.$$  

(5)

The action of a general POVM $\{A_k\}$ on $|\Psi_{ABC}\rangle$ could be described in a similar way as

$${A_k}|\Psi_{ABC}\rangle = \langle k_{AE}|U_{AE}(|\Psi_{ABC}\rangle \otimes |0_E\rangle) = \sum_{k'} \sqrt{p_{k'k}} |k_{AE}\rangle |\psi_{BC}\rangle,$$

(6)

To output the ensemble of pure states of Eq. (6) through POVM action, we revise the POVM (by partitioning the operators $\{A_k\}$ into $\{A_{k'k} = |k'\rangle\langle k'|A_k; k' = 1, \cdots, d\}$ with $d$ the dimension of $A$. It is then readily seen that the new POVMs $\{A_{k'k}\}$ could give rise to the general ensemble of relative states in Eq. (5):

$$A_{k'k} |\Psi_{ABC}\rangle \rightarrow \{p_{k'k}, |\psi_{BC}\rangle\}.$$  

(9)

The relation of (3) and (4) suggests a scheme to quantify quantum discord and EoF (or the $d$-component EoF) through building purifications of given mixed states. For example, in view that the EoF of mixed states of two-qubit systems has already been perfectly resolved [14], it indicates that the discord of all $n \times 2$ ($n \geq 2$) density matrices with no more than two nonzero eigenvalues can be achieved accordingly. Furthermore, by employing Eq. (4) and the similar relation for $S_{II}(\rho_A |C)$, one obtains

$$Q^A_{AB} - E(\rho_{AB}) = Q^{AC}_{AC} - Q^{AC}_{CA}.$$  

(7)

At this stage, it is clear that the ordering relation of the two quantities, $Q^{AC}_{AC}$ and $E(\rho_{AB})$, is essentially connected to the asymmetric property of quantum discord, reflected via the lateral $\rho_{AC}$ (or $\rho_{BC}$ if we consider $Q^{AC}_{AC}$ in stead) in the purification. In what follows we shall apply the scheme on some concrete quantum states so as to evaluate the amount of their discord and EoF and the ordering relation.

Quantum discord and entanglement in pure states of three qubits. It is direct to apply the above scheme to solve the issue for arbitrary two-qubit density matrices reduced from three-qubit pure states. In view that a three-qubit pure state can be expressed generally as [13]

$$|\psi_{ABC}\rangle = \lambda_0|000\rangle + \lambda_1 e^{i\phi}|010\rangle + \lambda_2|101\rangle + \lambda_3|110\rangle + \lambda_4|111\rangle,$$

(8)

the EoF of any pair could be worked out explicitly via the formula developed by Wootters [14],

$$E(\rho_{XY}) = -x \log_2 x - (1 - x) \log_2 (1 - x),$$

(9)

where $x = \frac{1}{2} [1 + \sqrt{1 - C^2(\rho_{XY})}]$ and the concurrence is obtained as

$$C(\rho_{AB}) = 2\lambda_0 \lambda_3,\quad C(\rho_{BC}) = 2\lambda_0 \lambda_2,$$

$$C(\rho_{AC}) = 2|\lambda_2 \lambda_3 - \lambda_1 \lambda_4 e^{i\phi}|.$$  

(10)

Since the optimal ensemble decomposition realizing the minimal average entanglement for each $\rho_{XY}$ here has only two components, it can be achieved by projective measurements on the third party $Z$. So there is

$$S_{II}(\rho_{XZ} |Z) = S_{II}(\rho_{XY} |Y) = E(\rho_{XY}).$$  

The conditional entropy has been derived, the discord of each $\rho_{ZX}$ can be directly obtained according to Eq. (7).

To illustrate the relation (7), we note that for the case $\lambda_2 = \lambda_3$, the state $\rho_{AC}$ is symmetric under permutation.
hence $Q_{AC} = Q_{CA}$. Consequently, there is

$$Q_{AB} = E(\rho_{AB}) = -\sum_{++,+-,+-} \frac{1 \pm \Delta}{2} \log_2 \frac{1 \pm \Delta}{2},$$

(11)

where $\Delta = \sqrt{1 - \lambda_0^2}$.

Quantum discord in $4 \times 4$ systems with no more than two nonzero eigenvalues. The discord of any $n \times n$ system $\rho_{AB}$ with only two nonzero eigenvalues can be recast to that of a $4 \times 4$ system. This can be readily seen that for the purification $|\psi_{ABC}\rangle$ of $\rho_{AB}$ the relative system $C$ could be of two dimension, so that the reduced density matrix $\rho_{BC}$ (hence $\rho_A$) has at most four nonzero eigenvalues. Since the $\text{EoF}$ of two binary systems $\rho_{BC}$ has perfectly resolved, it leads to the fact that the discord of any such states can be explicitly obtained. To illustrate, we present below an example of four-parameter family of rank-2 states formed as

$$\rho_{AB} = p_1|\psi_1\rangle \langle \psi_1| + p_2|\psi_2\rangle \langle \psi_2|,$$

(12)

where

$$|\psi_1\rangle = \cos \phi|00\rangle + \sin \phi|11\rangle,$$

$$|\psi_2\rangle = \sin \phi|a_30\rangle + \cos \phi|a_41\rangle,$$

(13)

are two normalized eigenvectors of $\rho_{AB}$ with

$$|a_3\rangle = \cos \theta_1|1\rangle + \sin \theta_1|2\rangle,$$

$$|a_4\rangle = \cos \theta_2|0\rangle + \sin \theta_2|3\rangle.$$

(14)

To calculate the quantum discord in Eq. (2), it is easy to obtain that $S(\rho_{AB}) = -\sum_{i=1}^2 p_i \log p_i$ and $S(\rho_A) = -\sum_{i=1}^4 \lambda_i \log \lambda_i$, where

$$\lambda_{1,2} = \frac{1}{2} \sin^2 \phi \left( 1 \pm \sqrt{1 - 4p_1p_2 \sin^2 \theta_1^2} \right),$$

$$\lambda_{3,4} = \frac{1}{2} \cos^2 \phi \left( 1 \pm \sqrt{1 - 4p_1p_2 \sin^2 \theta_2^2} \right).$$

(15)

The conditional entropy $S(\rho_B|A)$ can be derived via the equality of Eq. (4) and the purification herein could be expressed as $|\psi_{ABC}\rangle = \sqrt{p_1}|\psi_1\rangle|0C\rangle + \sqrt{p_2}|\psi_2\rangle|1C\rangle$. Note that the optimal ensemble decomposition realizing $E(\rho_{BC})$ has four components [14], this very ensemble can be achieved through outcomes of the projective measurements on $A$ in view that dim $A = 4$. This leads to the relation $S_I(\rho_B|A) = S_{II}(\rho_B|A) = E(\rho_{BC})$ for the present system. Explicitly, its value is given by the formula of Eq. (9) and the corresponding concurrence is now obtained as $C(\rho_{BC}) = \max\{0, 2\lambda_{m} - \sum_{i=1}^4 \lambda_i\}$, where $\lambda_m$ is the largest of

$$\lambda_{1,2} = \frac{1}{2} \sin^2 \phi \left( \sqrt{1 - (p_1 - p_2)^2} \right),$$

$$\lambda_{3,4} = \frac{1}{2} \cos^2 \phi \left( \sqrt{1 - (p_1 - p_2)^2} \right).$$

(16)

Deriving entanglement of formation via quantum discord. The quantitative calculation of $\text{EoF}$ for mixed states is notoriously difficult and the explicit expression is derived only for two-qubit systems [14] and very limited cases of high dimensional systems [18]. Noteworthy, the derivation of the relation of quantum correlations in tripartite purifications suggests also a distinct way to calculate $\text{EoF}$ in virtue of the conditional entropy. In particular, let us consider the states $\rho_{AB}$ of a $4 \times 4$ system given by Eq. (12). By examining the purification $|\psi_{ABC}\rangle$ it is seen that the resulting state $\rho_{BC}$ is an $X$-class two-qubit state, with the nonzero elements being

$$\rho_{BC}^{11} = p_1 \cos^2 \phi, \quad \rho_{BC}^{14} = p_1 p_2 \cos^2 \phi \cos \theta_2,$$

$$\rho_{BC}^{22} = p_2 \sin^2 \phi, \quad \rho_{BC}^{23} = p_2 \sin^2 \phi \cos \theta_1,$$

$$\rho_{BC}^{33} = p_1 \sin^2 \phi, \quad \rho_{BC}^{44} = p_2 \cos^2 \phi.$$

(17)

In the two-qubit case, it has been proved [17] that the projective measurement is the optimal POVM to minimize the conditional entropy, and evaluation of it for the X-class state has been resolved in Ref. [12]. According to the scheme proposed previously, it means $E(\rho_{AB}) = E(\rho_{BC})$ and its expression can be explicitly calculated. Particularly, for the case of $p_1 = p_2 = 1/2$, the state $\rho_{BC}$ reduces to a Bell-diagonal state (i.e., $\rho_{BC} = |I2\rangle/2$). The conditional entropy $S(\rho_{BC}|C)$ in this case has a concise expression (11) and so does the $\text{EoF}$ of $\rho_{AB}$,

$$E(\rho_{AB}) = S(\rho_B|C) = -\sum_{++,+-,+-} \frac{1 \pm \chi}{2} \log_2 \frac{1 \pm \chi}{2},$$

(18)

where $\chi = \max\{ |\chi_1|, |\chi_2|, |\chi_3| \}$, with

$$\chi_1 = -\cos 2\phi, \quad \chi_{2,3} = \cos^2 \phi \cos \theta_1 \pm \sin^2 \phi \cos \theta_1.$$  

(19)

The calculation above actually offers a full characterization of the state [12] for both its quantum discord and $\text{EoF}$. We plot in Fig. 1 the two quantities as functions of $\phi$, where $p_{1,2} = 1/2$, $\theta_1 = 0$, and $\theta_2 = \pi/3$. The result shows that the $\text{EoF}$ is lower than the discord as $\sin^2 \phi \lesssim 0.070$ and $\sin^2 \phi \gtrsim 0.711$, and larger than the discord in the range $0.070 < \sin^2 \phi < 0.711$.

As a final proposal of the paper we apply the derived results of quantification on discord and $\text{EoF}$ to characterize their dynamical behavior in a typical physical process. Consider a two-qubit system initially prepared in the state $|\psi_{AB}\rangle = \alpha|00\rangle + |\beta|11\rangle$, with $|\alpha|^2 + |\beta|^2 = 1$. Suppose that one of the qubit is subjected to a phase-damping environment (which can be realized, e.g., in optical systems as one of the photon passes through a phase-damping channel [18]). The system will then evolve as

$$\rho_{AB} = |\alpha|^2|00\rangle\langle 00| + |\beta|^2|11\rangle\langle 11| + e^{-\gamma t}(\alpha^*|\alpha|00\langle 11| + \alpha|\beta|11\langle 00),$$

(20)

with the phase-damping rate $\gamma$. Since the state $\rho_{AB}$ has only two nonzero eigenvalues, its quantum discord can be worked out explicitly via the above derived results upon its purification $|\psi_{ABC}\rangle$ of the three-qubit system. It turns out that $\rho_{BC}$ and $\rho_{AC}$ reduced
Three-qubit states and a class of rank-2 mixed states of 4 × 2 systems. In its applications to physical systems, we show that the derived result of quantification on the discord and EoF enables us to characterize their dynamical behavior in certain typical physical processes. Finally, we mention other applications proposed recently concerning the duality relation of quantum discord and EoF, e.g., resolution of EoF for a class of Gaussian states [19], and the role of them in relation to the power of deterministic quantum computation [20].
