Introduction

Stroke occurs in the blood supply to brain is blocked and this reduced the transport of oxygen and nutrients, which can cause neurons to damage. Cerebral ischemia resulted from low oxygen and glucose supply evidently decreases the formation of ATP (1-3). Brain ischemia injury is well known that it increases reactive oxygen species (ROS) generation and inflammatory reactions (4). The reports have shown that ischemia/reperfusion of brain always cause cell damage by oxidative stress (2, 3). Previously we reported that the sesamin protected brain and neuron from cerebral ischemia and hypoxic injuries (4-6).

The cerebral ischemia or hypoxia-induced ROS and cytokine could be eliminated by the antioxidants (7). The PC12 cells of rat pheochromacytoma and the BV-2 cells of murine microglia were well known as neuronal stress models (4, 5). Especially, the survival pathways including extracellular signal-regulated kinase (ERK), c-Jun N-terminal kinase (JNK) and p38 mitogen-activated protein kinase (MAPK) signaling pathways would be activated by subjecting with ROS in PC12 or BV-2 cells (4, 5). The cerebral ischemia induces apoptosis in the brain is identified by activation of caspase-3 (8). Therefore, a compound, 1, 2-bis [(3-methoxyphenyl) methyl] ethane-1, 2-dicarboxylic acid (MMEDA), was investigated for its neuroprotective effect in the present study. Therefore, the possible mechanism of MMEDA was examined with ischemic brain and cell hypoxia models for its antioxidant, anti-inflammatory properties, and the cell signal of hypoxia-induced survival and apoptotic pathways.

Materials and Methods

Reagents

Dimethylsulfoxide was obtained from Sigma-Aldrich Chemical (St Louis, MO, USA), Porcine polar brain lipid (PBL) was purchased from Avanti Polar Lipids Inc (Alabaster, AL, USA), 2',7'-Dichlorodihydrofluorescein diacetate (H2DCF-DA) was obtained from Molecular Probe (Eugene, Oregon, USA), Fetal bovine serum (FBS) was obtained from Gibco Invitrogen (Grand Island, NY, USA).
USA). Dulbecco’s Modified Eagle's medium (DMEM) were purchased from GIBCO (Grand Island, NY, USA). Anti-phospho-p38, ERK, JNK, and β-actin antibodies were purchased from Abcam (Cambridge, UK). Anti-Akt1 (pSer(473)) antibody was purchased from Calbiochem (Darmstadt, Germany). 1, 2-bis[(3-methoxyphenyl)methyl]ethane-1, 2-dicarboxylic acid (MMEDA) was donated by Joben Bio-Medical Co (Kaohsiung, Taiwan).

**Animal study**

Twenty Sprague Dawley (SD) rats (male, 200 ~ 250 g) were obtained from BioLASCO (Taipei, Taiwan) and divided into the control (normal saline), and MMEDA groups randomly. The experiment was approved by Institutional Animal Care and Use Committee, Taichung Veterans General Hospital (IACUC LA-97490). Rats were injected intraperitoneally (IP) with MMEDA (10 mg/kg) 90 min after MACO experiment. Each SD rat was anesthetized with chlorohydrate (400 mg/kg) IP and its body temperature was maintained at 37 °C with a heating pad (CMA/150). A midline neck incision was made and the right carotid artery was exposed and separated from the vago-sympathetic trunk. The right carotid artery was loosely encircled with a 4-0 suture for later occlusion. The SD rat’s head was placed in a stereotaxic frame (David Kopf, CA, USA) with the nose bar positioned 4.0 mm below the horizontal line. Following a midline incision, the skull was partially removed to expose the right middle cerebral artery. The middle cerebral artery was loosely encircled with an 8-0 suture for later occlusion. A focal cerebral ischemia was induced by occlusion of the right common carotid artery and the right cerebral artery (MCAO) for 60 min, followed by reperfusion. A laser probe (0.8 mm in diameter) of a Laser Doppler Blood Flow monitor (MBF 3D, Moor Instruments, Axminster, UK) was positioned onto the cortex with its tip close to the middle of the cerebral artery. Cerebral blood flow dropped to less than 5% of basal after the occlusion of the MCAO. Cerebral blood flow reached its minimal levels within 5 min after the start of the occlusion and was confirmed to remain at this level throughout the monitoring period to ensure the validity of the stroke model. Twenty-four hours after cerebral ischemia, each SD rat was anesthetized and perfused transcardially with isotonic heparinized saline and 2,3,5-triphenyltetrazolium chloride (TTC). The brain was then removed and sliced into five 2-mm-thick coronal sections for TTC staining.

**Cell culture**

The BV-2 cell line was maintained in DMEM supplemented with 10% (v/v) FBS in a humidified incubator under 5% CO₂ at 37 °C. The PC12 cell line was maintained in DMEM supplemented with 10% FBS, 5% horse serum, at 37 °C under 5% CO₂. Confluent cultures were passaged by trypsinization. In all experiments, the cells were treated with 1, 10, 50 μM of MMEDA immediately before hypoxia. MMEDA was dissolved in 95% alcohol. The final concentration of alcohol added to cells never exceeded 0.1% (v/v).

**Hypoxia**

In experiment, culture media were replaced with glucose-free DMEM, then, gassed with 85% N₂, 10% H₂, and 5% CO₂ for various time periods in the absence or presence of various doses of MMEDA.

**MTT assay**

Cell viability was measured using blue formazan that was metabolized from colorless 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) by mitochondrial dehydrogenases, which are active only in live cells. PC12 or BV2 cells were pre-incubated in 24-well plates at a density of 5×10⁵ cells per well for 24 hr. Cells incubated with various concentrations of MMEDA (1, 10, 50 μM) were under hypoxia for 30 min, and incubated in 0.5 mg/ml MTT at 37 °C. One hour later, 200 μl of solubilization solution were added to each well and absorption values read at 540 nm on microtiter plate reader (spectraMAX 340, Molecular Devices, Sunnyvale, CA, USA). Data were expressed as the mean percent of viable cells vs. control.

**LDH assay**

Cytotoxicity was determined by measuring the release of LDH. PC12 or BV-2 cells treated with various concentrations of MMEDA were stressed with hypoxia for one hour and the supernatant was then assayed for LDH activity. An absorbance was read at 490/630 nm using a spectraMAX 340 microtiter plate reader. Data were expressed as the mean percent of viable cells vs. the control.

**Generation of reactive oxygen species**

Intracellular accumulation of ROS was determined using H₂DCF-DA, which is a non-fluorescent compound that accumulates in cells following deacetylation. H₂DCF then reacts with ROS to form fluorescent dichlorofluorescein (DCF). PC12 cells were plated in 96-well plates and grown for 24 hr before addition of DMEM plus 10 μM H₂DCF-DA, incubated for 60 min at 37 °C, and treated with various concentrations of MMEDA for hypoxia 30 min. Cells were then washed twice at room temperature with Hank’s balanced salt solution (HBSS without phenol red). Cellular fluorescence was measured on a Fluoreskan Ascent fluorometer (Labystems Oy, Helsinki, Finland) using an excitation wavelength of 485 nm and emission wavelength of 538 nm.

**Measurement of PGE₂ assay**

PGE₂ was measured using ELISA kits (R&D, Minneapolis, MN, USA). The absorbance at 450 nm was determined using a microplate reader (spectraMAX 340).
Figure 1. The chemical structure of sesamin and MMEDA

β-actin proteins for neuron cells were detected by a chemiluminescence detection system according to the manufacturer’s instructions (ECL, Amersham, Berkshire, UK).

Lipid peroxidation
Lipid peroxidation is quantified by measuring malondialdehyde (MDA) of PC12 cells and brain tissue of SD rats by lipid peroxidation (LPO) assay kit (Cayman). This kit works on the principle of condensation of one molecule of either MDA or 4-hydroxyalkenals with two molecules of N-methyl-2-phenylindole to yield a stable chromophore. MDA levels were assayed by measuring the amount expressed in $5 \times 10^5$ cells of PC12 and SD brain tissue, and the absorbance at 500 nm was determined using a microplate reader (spectraMAX 340).

Statistical analysis
Data were expressed as the mean ± SEM. In animal study, TTC data were analyzed by analysis of variance (ANOVA) with Student’s t-tests. A $P$ value less than 0.05 was considered to be statistically significant. For in vitro study with single variable comparisons, Student’s t-test was used. For multiple variable comparisons, data were analyzed by one-way ANOVA followed by Scheffe’s test.

Results

The effect of MMEDA on the cerebral ischemia
SD rats treated IP with MMEDA (10 mg/kg) 90 min after MCAO-induced ischemia reduced 41% of the infarct size as compared to the cerebral ischemia group (from $582.46±13.67$ mm to $343.07±15.79$ mm, $P<0.05$; Figure 2A).

The protection of MMEDA against hypoxia
The neuroprotection of MMEDA were investigated by hypoxia model. Hypoxia can induce damage neuronal cells, therefore the cell viability was measured using MTT assay and the cytosol LDH released was measured using LDH ELISA assay from PC12 or BV-2 cells. In Figure 3B, the cell viability of PC12 cells subjected hypoxia for 30 min was increased by the presence of MMEDA (1, 10, 50 μM).
MMEDA against ischemic/hypoxic neuronal injury

Hung et al.

Iran J Basic Med Sci, Vol. 20, No. 12, Dec 2017

Figure 3. Effect of MMEDA on cell viability and cytotoxicity of PC12 cells under hypoxia. The cells were treated with hypoxia alone or in the presence of various concentrations (1, 10, 50 µM) of MMEDA for 30 min. Cell viability of PC12 (A) was increased and the LDH release reduced (B) from hypoxia dose-dependently by MMEDA. Data are expressed as mean ± SEM of three independent experiments in triplicate. *: P<0.05 as compared to the hypoxia control.

Hyoxia-induced LDH released was also decreased by MMEDA (P<0.05, Figure 3A). Similarly, BV-2 cells were protected by MMEDA under hypoxia (data not shown).

ROS scavenging

The neuronal cells induce free radicals release by hypoxia stress. Subjecting with hypoxia 30 mins, ROS (as DCF signal) was increased 60% in BV-2 cells in compared with the control cells. MMEDA protected cells against hypoxia-induced cell toxicity by scavenging the ROS accumulation level, was decreased 23 and 26% in 10, 50 µM of MMEDA (Figure 4A). The increased MDA level was suppressed by MMEDA in hypoxia-stressed BV-2 cells. MDA level of the MMEDA group was decreased 17 % (from 154±8 µM to 128±7 µM) as compared to the hypoxic group (Figure 4B, P<0.05).

MMEDA inhibited PGE2

We further examined the anti-inflammatory property of MMEDA on hypoxia-induced PGE2 production. BV-2 cells were pretreated with 1, 10, 50 µM of MMEDA, and then exposed to hypoxia for 30 min. The MMEDA (10 and 50 µM) dose-dependently decreased PGE2 release 29 and 45% level of BV-2 cells (P<0.05, Figure 4C).

Figure 4. Figure 4. Effects of MMEDA on hypoxia-induced ROS generation, MDA and PGE2 productions. BV-2 cells were treated with 1, 10, 50 µM of MMEDA for 30 min. MMEDA reduced the generation of ROS under hypoxia in BV-2 cells (A). MDA of PC12 cells were induced by 30-min hypoxia and reduced by MMEDA (B). BV-2 cells were treated with 1, 10, 50 µM of MMEDA under hypoxia 30 min. MMEDA of 10 and 50 µM, concentration-dependently reduced hypoxia-induced PGE2 production from BV-2 cells (C). Data are expressed as mean±SEM of 3 independent experiments in triplicate. *: P<0.05 as compared to the hypoxia control

MMEDA inhibited hypoxia-induced JNK MAPK, caspase-3 activation and JNK mRNA expression

The effects of MMEDA (1, 10, 50 µM) on hypoxia-induced signaling pathways were evaluated by Western blot assay (Figure 5A). There is no effect of the phospho-ERK and P38 protein expression subjected to 10 min hypoxia in PC12 cells. The 50 µM MMEDA reduced expression of the phospho-JNK (63%), and caspase-3 (70%), respectively for the 10 min hypoxia-induced PC12 cells (* P<0.05; Figure 5A).
The free radical ROS production in the brain contributed to the degenerative processes of neuron (9, 10). Reports show that the dietary-derived antioxidants inhibit the hypoxia-exposed inflammation response existence neuroprotective potential (11, 12). In our previous studies sesamin and its related structure were supported the protective effect on the hypoxia-stressed inflammatory and oxidative stress (5, 13). There is a similar effect of MMEDA, a sesamin novel derivative. Protective effect of MMEDA on hypoxia-stressed MDA might be through the activation of antioxidant signaling pathway such as Nrf2/ARE (14).

Western blot showed that hypoxia of 10 min could significantly activate the phospho-MAPKs, and caspase-3 expression in PC12 cells. Inhibition of apoptotic pathways by decreasing the phospho-JNK MAPK and caspase-3 expression could be expected to be beneficial in damage involving microglia activation and inflammation. The specific inhibitors of JNK MAPK would provide the reducing of inflammation and neuroprotective effects (4, 15, 16). Studies reported that the various antioxidant compounds inhibit JNK MAPK signal expression in microglia represent potential anti-inflammatory effects and neuroprotection (5, 17, 18). In addition, antioxidants inhibit JNK MAPK signal expression in neuron and cardiomyocyte cells represent potential protective effects from hypoxic injury (5, 19-21). We know that the sesamin regulate microglial activities by inhibition of the intracerebral hemorrhage-induced ERK cell signal pathway of MAPK and protect neurons from hypoxia damage by inhibition of hypoxia-induced ERK, JNK, p38 MAPK (5, 22). The Western blot show MMEDA also inhibited phospho-JNK MAPK expression in PC12 cells subjected to hypoxia significantly (Figure 5). Studies reported that hypoxia activates MAPK and apoptosis factor caspase-3 cell signal expression in vitro and in vivo (4, 8). Therefore, we evaluated the effect of MMEDA on the survival and apoptotic signaling pathways including phospho-MAP kinases (JNK, ERK, p38), and Caspase-3 with hypoxia-stressed PC12 cells. Western blot analysis revealed that MMEDA (10 and 50 μM) significantly reduced phospho-JNK MAPK, and caspase-3 expression in PC12 cells as compared to hypoxia controls (Figure 5A, 5B). The results suggested that the MMEDA repaired the cell viability under hypoxic stress (Figure 3) through survival and apoptotic signaling pathways in PC12 cells. This consistent with a research that the Tat-glyoxalase protein protects neuronal cells from H2O2-induced neuron damage, and DNA fragmentation by through with inhibition of caspase-3 and MAP kinase expression, and then ameliorate ischemic brain injury (23).

Previous studies shown that neuroprotection of antioxidants are due to increasing the antioxidative

### Figure 5. MMEDA inhibited hypoxia-induced phospho-JNK MAP kinase and JNK mRNA expression.

The effect of MMEDA (1, 10, 50 μM) on hypoxia-activated cell signaling pathways was determined by Western blotting under hypoxia stress in PC12 cells for 10 min. MMEDA effectively reduced the activation of JNK MAP kinase and caspase-3 in PC12 cells (A). PC12 cells were treated with MMEDA and subjected to hypoxia for 10 min. Levels of JNK, and β-actin mRNA were assayed by RT-PCR (B). Values represent the mean from three independent experiments. MMEDA decreased JNK mRNA as compared with that of the hypoxia. Data are expressed as mean±SEM of three independent experiments. *: P<0.05 as compared to hypoxia control.

PC12 cells were treated with MMEDA and subjected to hypoxia for 10 min. Levels of JNK, and β-actin mRNA was assayed by RT-PCR (5B). MMEDA decreased JNK mRNA as compared with that of the hypoxia and the 50 μM MMEDA reduced 63% expression of the JNK mRNA (*P<0.05; Figure 5B).

### Discussion

This research showed that the MMEDA (10, 50 μM) significantly protected SD rats from the focal cerebral ischemia damage. And, the MMEDA protected the BV-2 or PC12 cells from hypoxia-induced cell cytotoxicity, ROS generation and MDA levels.
enzymes, or scavenging of ROS and preventing calcium release (5). Recently, a study shows that resveratrol and metabolites activate heme oxygenase-1 (HO-1) by increasing cell signal of Nrf2/ARE protein expression, and reduce oxidative stress (14). According to MMEDA was able to inhibit MDA generation and 23~26% ROS, and 29~45% of PGE2 production of hypoxia stress. The free radical ROS could induce cell damage by upregulating MAPK expression (24). The MMEDA might downstream inflammatory proteins by way of the suppression of ROS generation which would reduce the activation of PGE2 in BV-2 cells subjected with hypoxia. The caspase-3 is the key point apoptosis factor for cells (23). Pretreating with MMEDA (100 μM) alone was not toxic to PC12/BV-2 cells (data not shown) and MMEDA at the concentrations of 10 and 50 μM inhibited the inflammation response, however, there is no effect of 1 μM MMEDA on the PGE2 response in hypoxia-stressed BV-2 cells (Figure 4C). The MMEDA significantly restored the infarct size (about 41%) of the focal cerebral ischemic brain as compared to the control group SD rats. Although the precise mechanism of MMEDA neuroprotection is not clear, the present in vitro and in vivo results suggest that its protection might be involved with the suppression of ROS and inflammation during cerebral ischemia.

Conclusion

The present study shows that MMEDA restored the brain subjected to the focal cerebral ischemia in vivo and, protected the BV-2 or PC12 cells from hypoxia-induced cell cytotoxicity in vitro. It also neutralized ROS generation and reduced lipid peroxidation in the BV-2 cells subjected to hypoxia. The protective mechanisms of MMEDA might be involved with the downregulation of phospho-JNK MAPK, and caspase-3 signal pathway expression. Therefore, the MMEDA should have a neuroprotective effect against ischemia.

Acknowledgment

The results described in this paper were part of student thesis. This study was supported in part by grant from Taichung Veterans General Hospital, Taiwan. We are grateful of manuscript proofreading support of prof K-C Jeng.
