ABSTRACT

Purpose The presence of distinct child and adolescent mental health services (CAMHS) and adult mental health services (AMHS) impacts continuity of mental health treatment for young people. However, we do not know the extent of discontinuity of care in Europe nor the effects of discontinuity on the mental health of young people. Current research is limited, as the majority of existing studies are retrospective, based on small samples or used non-standardised information from medical records. The MILESTONE prospective cohort study aims to examine associations between service use, mental health and other outcomes over 24 months, using information from self, parent and clinician reports.

Participants Seven hundred sixty-three young people from 39 CAMHS in 8 European countries, their parents and CAMHS clinicians who completed interviews and online questionnaires and were followed up for 2 years after reaching the upper age limit of the CAMHS they receive treatment at.

Findings to date This cohort profile describes the baseline characteristics of the MILESTONE cohort. The mental health of young people reaching the upper age limit of their CAMHS varied greatly in type and severity: 32.8% of young people reported clinical levels of self-reported problems and 18.6% were rated to be ‘markedly ill’, ‘severely ill’ or ‘among the most extremely ill’ by their clinician. Fifty-seven per cent of young people reported psychotropic medication use in the previous half year.

Strengths and limitations of this study

► The MILESTONE cohort study is the first study to prospectively examine the longitudinal association of service use and mental health outcomes over a 2-year follow-up period using information from young people themselves, their parents and their clinicians.

► Recruitment of child and adolescent mental health services (CAMHS) users within a wide range of services across eight countries resulted in a heterogeneous patient-population, which is very suitable for describing how sociodemographic and clinical characteristics are associated with the type of care young people receive in the 2 years after reaching the upper age limit of their CAMHS, irrespective of culture, mental health systems and transition policy.

► Although the representativeness of the cohort may be affected by a selection bias and selective dropout, it is unlikely that these will affect the validity of regression models investigating relationships between precursors and outcomes.

Future plans Analysis of longitudinal data from the MILESTONE cohort will be used to assess relationships between the demographic and clinical characteristics of young people reaching the upper age limit of their CAMHS
and the type of care the young person uses over the next 2 years, such as whether the young person transitions to AMHS. At 2 years follow-up, the mental health outcomes of young people following different care pathways will be compared.

**Trial registration number** NCT03013595.

**INTRODUCTION**

The presence of distinct child and adolescent mental health services (CAMHS) and adult mental health services (AMHS) impacts continuity of mental health treatment for young people. However, we do not know how many young people experience discontinuity, nor how this discontinuity may affect the mental health of young people reaching the upper age limit of the CAMHS they receive treatment at. Previous research reports a large variation in the proportion of CAMHS users that do not transition to AMHS, ranging from 30% to 84%. There are a few studies examining how demographic and clinical characteristics of CAMHS users are associated with transitioning to AMHS. These studies are consistent in showing that indicators of severity of psychopathology, such as a clinical classification of a bipolar or psychotic disorder, inpatient care and psychotropic medication use, are associated with a greater likelihood of transition to AMHS. However, the results are inconsistent with regard to sociodemographic characteristics, such as gender and living situation, or other factors such as the length of CAMHS use.

Most existing studies have been retrospective and used unstandardised information from medical records. Only few prospective studies have been conducted, mostly in small samples, within one CAMHS or within subsamples such as young people with autism spectrum disorders (ASD). Only 1 study, investigating 118 young people with ASD, included self-reported and parent-reported information. To date, no studies have been conducted that compare longitudinal mental health outcomes of young people who transition to AMHS with those who do not.

The MILESTONE cohort study was designed to prospectively examine service use, mental health and other outcomes over a 2-year follow-up period, in a cohort of 763 young people who have reached the upper age limit of their CAMHS in 8 European countries. The aims of the MILESTONE cohort study are to (1) assess the relationships between demographic and clinical characteristics of young people reaching the upper age limit of their CAMHS, whether the young person is referred from CAMHS to AMHS and the type of care the young person uses over the next 2 years, such as whether the young person transitions to AMHS; (2) determine the mental health outcomes of young people following different care pathways after 2 years follow-up. This cohort profile describes demographic and clinical characteristics of young people at baseline only.

**COHORT DESCRIPTION**

**Study design and participants**

A cluster randomised trial (NCT03013595) was embedded within the longitudinal cohort study, of which the protocol has been previously described by Singh et al. A total of 52 CAMHS in 8 countries (Belgium, Croatia, France, Germany, Ireland, Italy, the Netherlands and the UK) agreed to participate and fitted the service inclusion criteria: a service delivering medical and psychosocial interventions for children and adolescents with mental health problems or disorders and/or neuropsychiatric/developmental disorders, with a formal upper age limit for providing care and responsible for transfer of care to adult services. Highly specialised services for rare disorders and forensic services were excluded. Thirty-nine CAMHS were included in this cohort study (4 in Belgium, 2 in Croatia, 4 in France, 2 in Germany, 2 in Ireland, 8 in Italy, 6 in the Netherlands and 11 in the UK; see online supplemental table 1 for the number of participants recruited per country), which varied in size and types of services offered, including services run by a single psychiatrist/psychologist and services with multiple locations and teams. Thirteen CAMHS were excluded as they were in the trial intervention arm in which ‘managed transition’ was implemented. Managed transition included a structured assessment of young people regarding transition readiness and appropriateness, the results of which were fed back to CAMHS clinicians.

**Young people**

Figure 1 describes the flow of participants in the process of assessing eligibility, recruitment and follow-up. Between October 2015 and December 2016, CAMHS databases were scanned by local personnel, screening for eligible participants, that is, young people within a year of the upper age limit of the specific CAMHS (or 3 months after, if still in CAMHS) (n=6238). The upper age limit of the participating CAMHS was 18 years for two-thirds of services, or applied flexibly, varying between 16 and 19 years of age. A care coordinator and/or clinician assessed the young people for study inclusion criteria and sought the young person’s consent to be approached by a MILESTONE research assistant. In addition to the age criterion, the following inclusion criteria were applied: eligible young people had a mental disorder or were regular CAMHS service users, had an intelligence quotient (IQ) over 70 or no indication of intellectual impairment and were able to complete questionnaires and interviews (also see figure 1). The research assistant contacted the young person (and their parents, if the young person was legally a minor) with information about the study and consent forms. Country-specific consent procedures were followed, according to national laws as well as medical ethical committee regulations. A parent/carer (referred to as parents from hereon) and the young person’s main CAMHS clinician, or a mental health professional responsible for, or coordinating, the care for the young person, were also asked to participate in the study. The first assessment took place after consent was provided.

All participants in MILESTONE were to be followed up over a period of 2 years, in which three follow-up assessments took place (9, 15 and 24 months after baseline). Before each
Figure 1 Flow diagram of participants according to Consolidated Standards of Reporting Trials (CONSORT). CL, clinician; PC, parent/carer; YP, young person.
assessment, the participant was contacted by a research assistant and asked whether they would participate in the next assessment, after which the assessment would be planned (within a month of the calculated assessment timepoint, that is, between 8 and 10 months after baseline for the second assessment). A total of 48 young people (6.3%) withdrew from the study within this 24-month period. In addition, not all participating young people completed all measures at all timepoints: a total of 631 (82.7%) young people completed 1 or more questionnaires or interviews at 9 months follow-up, 573 (75.1%) at 15 months follow-up and 533 (69.9%) at 24 months follow-up.

Parents/carers and clinicians

In addition, a total of 651 parents and 699 CAMHS clinicians were recruited for completion of parent and clinician reported outcome measures. If a young person left CAMHS and moved onto a new service, a clinician from the new service was asked to participate. A total of 492 (reporting on 64.5% of young people) parents completed 1 or more questionnaires or interviews at 9 months follow-up, 473 (62.0%) and 432 (56.6%) parents completed measures at 15 and 24 months follow-up, respectively. The number of young people for whom a clinician provided any clinical information was 429 (56.2%) at 9 months, 222 (29.1%) at 15 months and 183 (24.0%) at 24 months follow-up. Among young people who reported receiving mental healthcare, clinical information was available for 85.0%, 72.6% and 69.5% at 9, 15 and 24 months, respectively.

Measures and procedure

At baseline and 24 months follow-up, assessments took place in the clinic, the participant’s home or other convenient location and lasted approximately 2 hours. To limit the burden on participants, the most important interviews and questionnaires were repeated at 9 and 15 months, most interviews were conducted by phone (some face-to-face) and questionnaires were completed online. Young people and parents were interviewed separately by the local MILESTONE research assistant and asked to complete a set of questionnaires online on the web-based HealthTracker platform. Paper and pencil were used when the HealthTracker platform could not be accessed. Measures that were not available in all languages (English, Dutch, Italian, Croatian, French and German) were translated and back translated before use. All research assistants were trained to administer the interviews and questionnaires and attended monthly international research assistant meetings by phone to ensure adherence to standard operating procedures and consistency between sites, countries and over time. Most young people received a gift voucher after completing the assessment (gift vouchers had a maximum value of €25; research ethics committees in Italy and Croatia did not allow gift vouchers) and travel costs were reimbursed.

An overview of the measures used in the MILESTONE cohort study is provided in table 1. The interviews focused on capturing information about the young person and parent’s sociodemographic information and the young person’s mental health in the 2 weeks prior to the assessment. This enabled completion of the Health of the Nation Outcome Scale for Children and Adolescents (HoNOSCA). Online questionnaires were used to assess emotional and behavioural problems, need for care, psychotic experiences, quality of life, everyday functional skills, independent behaviour, illness perception, life events and bullying, service and medication use, transition readiness and appropriateness. The clinician provided clinical information (and/or medical notes were reviewed, if accessible) which included clinical classifications registered in the medical records (based on the Diagnostic and Statistical Manual of Mental Disorders version IV or 5 and the International Classification of Diseases version 10), the Clinical Global Impression—Severity (CGI-S) and demographic information. The clinician was also asked to provide information for the purpose of rating the HoNOSCA (supplementing information from young person and/or parent interviews), if they had seen the young person within the past 2 weeks.

Patient and public involvement

Patient and public involvement was embedded in the MILESTONE cohort study and trial, by involving 10 young service users and carers from England and Ireland with experience of transition in mental health services from the outset. They provided feedback on the protocol and study documents; reviewed the outcomes measures and other study tools to ensure these were clear and not overly onerous for young people to complete; designed the intervention leaflet and other promotional materials; attended and contributed to project steering committee meetings; advised on recruitment and the engagement of young people; contributed to drafting the manuscripts and made presentations at local and national events. In the later stages of MILESTONE, nine parent/carers from across the north of England advised on the study dissemination outputs.

Missing data

Whether specific measures were administered to participants was dependent on whether or not the young person was using services at the time of assessment, and which type of services. Additionally, clinician participation at a particular assessment was entirely dependent on the young person’s service use. Due to an increasing proportion of young people no longer using services at follow-up assessments, the proportion of missing data at follow-up for measures such as clinician-rated severity of psychopathology (CGI-S) increased from 16.1% at T1, to 50.5% at T2, 76.9% at T3 and 81.1% at T4. Important outcome measures such as self-reported emotional and behavioural problems (Youth Self-Report/Adult Self-Report (YSR/ASR)), parent-reported emotional and behavioural problems (Child Behaviour Checklist/Adult Behaviour Checklist (CBCL/ABCL)) and mental health problems assessed with HoNOSCA were administered at

| Emotional and behavioural problems     | YP (QO: 0, 9, 15, 24)                  | Youth Self-Report (YSR) Adult Self-Report (ASR) Child Behaviour Checklist (CBCL) Adult Behaviour Checklist (ABCL)                      | YP (YSR/ASR) and PC reported (CBCL/ABCL) emotional and behavioural problems in the last 6 months in versions for YP under (YSR/CBCL) or over (ASR/ABCL) 18 years old. The Achenbach System of Empirically-Based Assessment (ASEBA) instruments have been used extensively in different contexts and have shown excellent psychometric properties. Raw scores were converted to t-scores (with a mean of 50 and a SD of 10) to allow comparison between ASEBA measures. Norm scores were used to differentiate between normal, borderline clinical, and clinically scoring young people. Higher scores indicate more emotional/behavioural problems. |
|                                        | PC (QO): 0, 9, 15, 24                  | Adult Behaviour Checklist (ABCL)                                                                                                  | The CGI-S is extensively used in psychiatric research and has proven useful in predicting suicidal ideation and behaviours. 32                                                                                                                                                                                                                                                                  | Single score measuring severity on a 7-point scale (higher scores indicating more severe problems). The CGI-S was used as a categorical variable in the analyses, with the following categories ‘not at all ill’ (score=1), ‘borderline/mildly/moderately ill’ (scores 2–4) and ‘markedly or more severely ill’ (scores 5–7). | Single score measuring severity on a 7-point scale (higher scores indicating more severe problems). The CGI-S was used as a categorical variable in the analyses, with the following categories ‘not at all ill’ (score=1), ‘borderline/mildly/moderately ill’ (scores 2–4) and ‘markedly or more severely ill’ (scores 5–7). |
| Clinician rated severity of psychopathology | CL (I): 0, 9, 15, 24                   | Clinical Global Impression — Severity scale (CGI-S)                                                                               | CL rated severity of psychopathology over the last week relative to other patients with similar problems.                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                   |
| Construct                  | Informant (method): assessed at m-f-u* | Instruments                                                                 | Description                                                                                                                                                                                                                                                                                                                                 | Psychometrics                                                                                                                                                                                                                                                                                                                                 | Scoring                                                                                                                                                                                                 |
|---------------------------|----------------------------------------|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Need for care             | YP (I): 0, 9, 15, 24 PC (I): 0, 9, 15, 24 CL (I): 0, 9, 15, 24               | The Health of the Nation Outcome Scale for Children and Adolescents (HoNOSCA) | Assesses YP’s health and need for care in the last 2 weeks. In the MILESTONE study, the HoNOSCA is rated by trained research assistants, based on the ‘mental health’- interview with the YP, PCs, the CL and/or medical records.                                                                 | Good interrater reliability cross-nationally, face validity and sensitivity to change in clinical use in adolescent CAMHS patients specifically. Within MILESTONE, research assistants were trained and regular meetings were held to discuss scoring issues and to improve scoring reliability. | Total score (ranging 0–52) of 13 health related domains ranging 0–4. Higher scores indicate more severe problems. Domains 14 and 15 are related to lack of information and access of services and not used in computing the HoNOSCA total mental health score. |
| Psychotic experiences    | YP: 0, 24                             | Development and Well-Being Assessment (DAWBA)                                | DAWBA assesses a range of psychiatric diagnoses through structured sections of the online questionnaire, among which psychotic experiences. The open sections of the DAWBA were omitted to limit the burden on the participants and to standardise the classification procedure. | The DAWBA psychotic experiences section proved valuable as a screening tool in the youth general population (it has not yet been validated in a clinical sample). | Respondents indicated whether the young person experienced a range of psychotic experiences, with response options ‘no’, ‘a little’, and ‘a lot’. The total number of a total of 10 experiences the young person experienced (either a little or a lot) was calculated.                                                   |
| Service use               | YP (OQ): 0, 9, 15, 24                  | CSSRI-EU (amended for use in a psychiatric setting)                         | Assesses inpatient and outpatient service use over the last 6 months in different settings (hospital, community and informal) and medication use over the last 6 months.                                                                                                                                                                                                 | The CSSRI-EU was found to be effective in tracing patterns of service use in an international population and made comparisons between different countries possible. | Dichotomous service use score over different service use types and quantity of service use (number of nights spent or number of visits multiplied by their average duration)                                                                                     |
| Current mental healthcare | YP (I): 0, 9, 15, 24                   | Part of sociodemographic interview                                         | Current mental healthcare was assessed with the questions ‘Are you currently using a mental health service?’ and ‘What mental health service are you currently accessing?’. The research assistant administering the interview could help the young person identify what type of care the young person was in care at if necessary. |                                                                                                                                                                                                                                                                            | Categorical answer categories                                                                                                                                                                                                                                           |
| Transition readiness and appropriateness | YP (OQ): 0 PC (OQ): 0 CL (OQ): 0       | Transition Readiness and Appropriateness Measure (TRAM)                     | The TRAM assessed the clinician’s transition recommendations and the availability of appropriate services (both in the CL version of the TRAM). The YP-version and PC-version were used to assess young people’s and parents’ need for ongoing treatment. | The TRAM has been established to be a reliable instrument for assessing transition readiness and appropriateness.                                                                                                                                                                                                                                 | Categorical answer categories                                                                                                                                                                                                                                           |

Table 1 Continued
| Construct                  | Informant (method): assessed at m f-u* | Instruments                                                                 | Description                                                                 | Psychometrics                                                                 | Scoring                                                                 |
|---------------------------|----------------------------------------|-----------------------------------------------------------------------------|----------------------------------------------------------------------------|--------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Quality of life           | YP (OQ): 0, 15, 24                     | World Health Organization Quality of Life Brief Inventory (WHOQOL-BREF)      | YP reports on quality of life in the last 2 weeks.                          | The WHOQOL-BREF has excellent psychometric properties. Internal consistency for assessing quality of life in adolescents is good and the instrument validly discriminated between adolescents with low and high levels of depressive symptoms. | To allow comparison to the WHOQOL-100, mean domain scores were calculated and multiplied by 4, yielding a 4–20 transformed mean score of quality of life score in 4 domains: psychological, physical, social and environmental quality of life. Higher scores indicate a higher quality of life. |
| Everyday functional skills| PC (OQ): 0, 15, 24                     | Specific Levels of Functioning (SLOF)                                       | Assesses YP’s everyday functional skills, ‘emphasizing patient’s current functioning and observable behaviour, as opposed to inferred mental or emotional states.’ | The SLOF domains have acceptable internal consistencies (except for a Cronbach’s alpha of 0.55 for physical functioning) and good concurrent validity. | Average everyday functional skill-scores ranging from 1 to 5 on 6 domains: physical functioning, personal care, interpersonal relationships, social acceptability, activities and work skills, with higher scores indicating more everyday functional skills. |
| Independent behaviour     | YP (OQ): 0, 9, 15, 24                  | The Independent Behaviour During Consultations Scale (IBDCS)                 | YPs report on their independent behaviour on a 5-point Likert scale.       | Independence is a construct sensitive to change at the age of emerging adulthood and closely related to self-efficacy. | Average score of 7 items ranging from 0 to 4 (with higher scores indicating more independence). |
| Illness perception        | YP (OQ): 0, 24                         | Brief Illness Perception Questionnaire (B-IPQ)                              | Assesses the young person’s perception of their disorder.                   | The B-IPQ has been used extensively in medical research and to a lesser extent in psychiatric research specifically, and has good test-retest reliability and concurrent validity. | Average score per item ranging from 0 to 10 (higher scores indicating higher perceived threat). |

### Experiences

| Construct                  | Informant (method): assessed at m f-u* | Instruments                                                                 | Description                                                                 | Psychometrics                                                                 | Scoring                                                                 |
|---------------------------|----------------------------------------|-----------------------------------------------------------------------------|----------------------------------------------------------------------------|--------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Life events               | YP (OQ): 0, 9, 15, 24                  | Instrument developed specifically for MILESTONE to assess life events       | 13-item scale assessing 13 different life events such as accidents, deaths, separation over the last 9 months. |                                                                              | Total score indicating the number of life events experienced (ranging 0 to 13). |
| Bullying                  | YP (OQ): 0, 24                         | Adapted from Retrospective Bullying and Friendship Interview Schedule       | Assesses the YP’s experiences with bullying in different settings (school, at home, college). | The Retrospective Bullying and Friendship Interview Schedule has previously been used in various populations and was found to be predictive of mental health. | Bullying experiences were classified in four groups: YP who were the victim of bullying (victim), YP who were both the victim of bullying and bullied themselves as well (bully/victim), YP who bullied (bully) and YP who were not involved in bullying (non-involved). |

*m f-u=months of follow-up.
CAMHS, child and adolescent mental health services; CL, clinician; I, interview; OQ, online questionnaire; PC, parent/carer; YP, young person.
every timepoint. For these measures, the proportions of missing data per timepoint were: 10.5% at T1, 26.9% at T2, 33.2% at T3 and 37.4% at T4 for Y/ASR; 25.0% at T1, 37.5% at T2, 46.0% at T3 and 50.6% at T4 for C/ABCL and; 3.9% at T1, 18.7% at T2, 28.3% at T3 and 31.1% at T4 for HoNOSCA.

Patterns of missing data on severity of psychopathology (CGI-S) and problem levels (Y/ASR and C/ABCL) at baseline are presented in online supplemental table 2. Information from the parent was more frequently missing when young people reported more emotional/behavioural problems and when the clinician reported the young person was either ‘not at all ill’ or ‘markedly ill or more severe’. Missing information on young people’s or clinician’s assessment of severity of psychopathology was not associated with problem levels reported by the other informants.

The 48 young people who withdrew between the first and last assessment at 24 months follow-up had lower Y/ASR mean item scores at baseline (M=0.44, SD=0.25) than young people who did not withdraw (M=0.57, SD=0.28; t(38.915)=−2.910, p=0.006). Young people who withdrew did not differ from young people who did not withdraw on CGI-S scores (t(39.538)=1.339, p=0.188) and mean C/ABCL item scores (t(33.289)=1.112, p=0.274) at baseline. Young people who withdrew during follow-up were more likely to have a schizophrenia spectrum disorder (14.6%) than those who did not withdraw (4.3%; χ²(1, n=763)=7.934, p=0.005). Young people who withdrew did not differ from those who did not withdraw with regard to clinical classifications of depressive disorders (χ²(1, n=763)=0.848, p=0.357), anxiety disorders (χ²(1, n=763)=3.604, p=0.058), ASD (χ²(1, n=763)=309, p=0.579) or attention deficit/hyperactivity disorder (χ²(1, n=763)=2.360, p=0.125). We also did not find differences between young people who withdrew and those who did not with regard to gender (χ²(1, n=763)=1.017, p=0.313) or parental educational level (χ²(2, n=569)=4.449, p=0.108) at baseline.

**Findings to date**

This cohort profile describes the demographic and clinical characteristics of young people in the MILESTONE cohort as they reach the upper age limit of their CAMHS (i.e., results from young people’s baseline assessments only). The Consolidated Standards of Reporting Trials flow diagram (figure 1) illustrates recruitment of young people to the cohort study (n=763). Online supplemental table 1 provides an overview of the recruitment process by country. A total of 6238 young people attending CAMHS, approaching the service boundary of their respective service, were assessed for eligibility. During this process, many young people who had been included in the first database screening were found to be ineligible, as they were either no longer under treatment or were now too old to be recruited. A total of 3297 young people was found eligible, of which 568 (17.2%) were considered too unwell or unable to consent by their clinicians during the recruitment period. Care coordinators and clinicians introduced the MILESTONE study to 1692 (51.3% of all eligible) young people. For 1037 (31.5% of all eligible) young people, the research assistant did not have evidence that the study had been introduced and therefore could not contact the young person. Of all young people to which the study was introduced, a total of 297 (17.6%) did not agree to be contacted, 242 young people (14.3%) did not consent to participate and 7 young people (0.4%) were underage and had parents who did not consent. Of all young people to whom the study was introduced, 763 young people (45.1%) consented to participate and completed in the first assessment (before the first assessment, 25 young people withdrew). A total of 651 parents and 318 CAMHS clinicians (linked to 699 young people, as some clinicians treated more than one participant) were also included in the study.

**Sociodemographic characteristics**

Sociodemographic characteristics of the 763 young people in the MILESTONE cohort are presented in table 2. The age of recruited young people ranged from 15.2 to 19.6 years, with a mean of 17.5 years (SD=0.59). This corresponds with the upper age limits of the CAMHS, which ranged from 16 to 19 years, with a median age of 18 years. Demographic characteristics of parents and clinicians are presented in online supplemental table 3.

### Table 2: Sociodemographic characteristics of young people in the MILESTONE cohort

| Characteristic            | n (%) or mean (SD) |
|---------------------------|--------------------|

Note: percentages are based on n=763 for the total group.
Clinical characteristics
All measures are described in table 3 and figures 2 and 3.

Clinical classifications
Figure 2A shows the prevalence of clinical classifications of the MILESTONE cohort. The most common clinical classifications were depressive disorders (26.6%) followed by anxiety disorders (22.5%), attention deficit hyperactivity disorders (ADHD; 20.1%) and ASD; 14.9%. Fifty-eight per cent (n=443) of young people had one classification, 27.9% (n=213) had two classifications, and 10.2% (n=78) had three or more classifications. Among those with more than one classification (n=291), the most prevalent comorbidities were depressive disorder and anxiety disorder (n=32, 11.0%), ADHD and ASD (n=19, 6.5%) and ADHD with an anxiety disorder (n=11, 3.8%).

Emotional and behavioural problems
Figure 2B shows the proportion of normal, borderline and clinically scoring young people as well as the mean scores on total, internalising and externalising scales for both self-reported (YSR and ASR) and parent-reported (CBCL and ABCL) problems. About a third (32.8%) of young people and 42.3% of parents reported problems in the clinical range on the total problems scale, with more young people scoring in the clinical range of the internalising scale than in the externalising scale (both self and parent-reported).

Severity of mental health problems
Severity of psychopathology scores provided by the clinician on the CGI-S are presented in table 3. A total of 18.6% (n=142) of young people were rated to be ‘markedly ill’, ‘severely ill’ or ‘among the most extremely ill’ by the clinician over the past week. Lifetime and current suicidality as well as psychotic experiences were assessed as indicators of severity of psychopathology. A quarter of young people (25.7%) reported having tried to commit suicide. Thirty-one (4.1%) young people were rated to have suicidal intent or attempted suicide in the past 2 weeks (assessed with the ‘non-accidental self-harm’ domain of the HoNOSCA, with a score of 3 indicating ‘moderately severe suicidal intent or moderate non-hazardous self-harm’ and 4 indicating a serious suicidal attempt or serious deliberate self-injury). One in three young people (n=250; 32.8%) reported ever having one or more psychotic experiences, while 330 young people reported never having psychotic experiences (43.3%). Information on psychotic experiences was missing for 183 young people (n=24.0%). The total HoNOSCA score is another method for assessing the severity of mental health problems. Online supplemental figure 1 presents mean scores for the different HoNOSCA items. Young people scored highest (most severe and impairing problems) on ‘problems with emotional and related symptoms’ (M=1.97, SD=1.20) and ‘problems with overactivity, attention or concentration’ (M=1.33, SD=1.12).

Service use
Length of service use
The duration of service use varied from less than 1 year to more than 5 years (figure 3A). Young people with neurodevelopmental disorders had been attending CAMHS longest, with roughly half for more than 5 years (figure 3B). Those with disorders that most frequently emerge in adolescence/young adulthood, such as personality, mood, eating and schizophrenia spectrum disorders were less likely to have been attending CAMHS for more than 5 years, yet a third to more than half of young people with these disorders had been attending CAMHS for 2 years or longer.

Type of service use
Young people who visited mental health professionals in an outpatient setting (n=544; 71.3%; assessed with the Client Sociodemographic and Service Receipt Inventory EU version) visited their clinician with a median of 10 times in the previous half year (IQR=4–21.3). Young people who were admitted to a residential psychiatric facility or a residential rehabilitation setting (n=66, 8.7%) spent a median of 48.5 nights in this facility in the previous 6 months (IQR=12.0–91.8). Thirty-six per cent of young people who had visited their general practitioner in the 6 months before baseline assessment (n=277) and 11.1% had visited an emergency department (n=85; whether this visit was for mental health problems or other health problems is unknown). Fifty-seven per cent of young people (n=436) reported having used psychotropic medication in the previous half year. One in three young people used one type of psychotropic medication (n=224, 29.4%), 24.6% (n=188) used two or three different psychotropic medications and 3.1% (n=24) used four to five different psychotropic medications. Antidepressants were taken by almost one in three young people (n=216, 28.3%), psychostimulants by 14.4% of young people (n=110), antipsychotics by 12.1% (n=92), melatonin by 5.5% of young people (n=42) and 5.6% used benzodiazepines (n=43).

Impairment and everyday functional skills
Quality of life
Participants reported lowest on the psychological quality of life domain of the World Health Organization Quality of Life Brief Inventory compared with the other quality of life domains (table 3).

Everyday functional skills and independent behaviour
The level of physical functioning and personal care (measured with the Specific Levels of Functioning) of the majority of young people was assessed as self-sufficient by their parents (table 3). Independent behaviour during clinical consultations (with the Independent Behaviour During Consultations Scale) was also generally rated fairly highly. More than two-thirds of young people (n=500, 65.5%) regularly or more frequently participated in decisions regarding their treatment. Almost half of young
### Severity of mental health problems

|                                | n   | Mean (SD), median (IQR) or n (%) |
|--------------------------------|-----|----------------------------------|
| **Clinician rated severity of psychopathology (CGI-S)** | 640 |                                  |
| Not at all ill                 |     | 60 (7.9%)                        |
| Borderline/mildly/moderately ill | 438 | 438 (57.4%)                      |
| Markedly ill or more severe    | 142 | 142 (18.6%)                      |
| Missing                        | 123 | 123 (16.1%)                      |

### Impairment and functioning

|                                | n   | Mean (SD), median (IQR) |
|--------------------------------|-----|-------------------------|
| **Quality of life (WHOQOL-BREF; range 4–20)** | 692 |                         |
| Psychological                  |     | 12.03 (3.54)            |
| Physical                       |     | 14.71 (2.67)            |
| Social                         |     | 13.65 (3.27)            |
| Environmental                  |     | 15.02 (2.62)            |
| **Everyday functional skills (SLOF; range 1–5)** | 579 |                         |
| Physical functioning           |     | 5.00 (4.80, 5.00)       |
| Personal care skills           |     | 5.00 (4.57, 5.00)       |
| Interpersonal relationships    |     | 3.71 (3.00, 4.57)       |
| Social acceptability           |     | 4.57 (4.29, 5.00)       |
| Activities                     |     | 4.73 (4.27, 4.91)       |
| Work skills                    |     | 4.17 (3.33, 4.67)       |
| **Illness perception (B-IPQ; range 0–10)** | 610 | 5.47 (1.68)             |
| **Independent behaviour (IBDCS; range 0–4)** | 683 | 1.88 (0.91)             |

### Experiences

|                                | n   | Mean (SD), median (IQR) |
|--------------------------------|-----|-------------------------|
| **Life events (range 0–13)**   | 684 | 2.00 (1.00, 3.00)       |
| **Bullying**                   | 685 |                         |
| Victim                         |     | 310 (40.6%)             |
| Bully/victim                   |     | 116 (15.2%)             |
| Bully                          |     | 24 (3.2%)               |
| Non-involved                   |     | 235 (30.8%)             |
| Missing                        |     | 78 (10.2%)              |

*Percentages are based on n=763 for the total group.*

B-IPQ, Brief Illness Perception Questionnaire; CGI-S, Clinical Global Impression—Severity; HoNOSCA, Health of the Nation Outcome Scale for Children and Adolescents; IBDCS, Independent Behaviour During Consultations Scale; SLOF, Specific Levels of Functioning; WHOQOL-BREF, World Health Organization Quality of Life Brief Inventory.
people (n=334, 43.8%) attended consultations on their own regularly or more frequently.

**Illness perception**

Young people scored between 5 and 6 on the Brief Illness Perception Questionnaire on average, with scores ranging 0–10 (see table 3). In general, young people were most negative about how long the illness would continue (item mean of 6.89, SD=2.91 on a scale of ‘a very short time’ (0) to ‘forever’ (10)), yet moderately positive with regard to how well they felt they understood their illness (item mean=3.05, SD=2.56 on a scale of ‘very clearly’ (0) to ‘not at all’ (10)).

**Experiences**

One in five young people (n=160, 21.0%) reported that they had experienced no serious life events in the past 9 months, 41.5% had experienced one or two events (n=317) and 27.0% of young people (n=206) had experienced three life events or more (table 3).

Overall, having been bullied was more prevalent than bullying others: 40.6% of young people had been the victim of bullying in the past and 15.2% of young people had both been victimised and bullied others (table 3). Only 3.2% had bullied others without having been bullied themselves. A third (30.8%) of young people had experienced neither.

**STRENGTHS AND LIMITATIONS**

The MILESTONE cohort study has a number of strengths, such as its prospective design with a 2-year follow-up, and the recruitment of multiple informants. Standardised assessments were used to collect data on clinical characteristics, impairment and functioning, experiences and sociodemographic information. Additionally, the study had strong patient and public involvement. The 39 participating CAMHS reflect a wide range of services, varying in size and ranging from community to specialist and/or...
academic hospital-based services in countries with differences in culture, training and concepts of mental health as well as differences in mental health policy and service organisation. There are also several potential limitations to the MILESTONE cohort study. The first and most important limitation pertains to the representativeness of the MILESTONE cohort, due to potential selection bias. The CAMHS from which young people were recruited were not selected randomly, but affiliated with the MILESTONE consortium and their network of mental health organisations. The second indication of a potential selection bias relates to the response rate of 45.1%. The dependency on medical records and clinicians for determining eligibility, approaching and informing participants, and for gaining consent is known to make the screening and recruitment process ethically, legally and technically challenging. This dependency also complicated registration of the recruitment, resulting in missing information. Unfortunately, we were not able to compare participating young people to those who declined participation, for example, on severity of psychopathology, by conducting a non-response analysis. Medical ethical committees reviewing the MILESTONE protocol did not allow collection of data from young people who had not consented to participating in the study, unless written consent was provided. Since only few young people consented to collecting basic medical information, we concluded our non-response analysis would also be biased and was therefore not considered useful. An analysis of missing data among participants indicated a potential bias in participation of parents, with a higher proportion of missing parental information in young people with higher self-reported problems levels and more severe clinician-rated psychopathology.

Ultimately, the response rate of 45.1% in the MILESTONE cohort is similar to response rates in other cohort studies on adolescents with mental health problems. Additionally, even though there are indications of selective drop-out, the proportion of young people that withdrew in the 24-month follow-up period was low. A possible selection bias and selective drop-out may affect the representativeness of the MILESTONE cohort, but a representative sample may not be required to generalise the
findings from the MILESTONE cohort to other clinical populations of young people in the transition age. Selection bias and selective drop-out are unlikely to substantially affect the validity of regression models. In analyses investigating the longitudinal association between precursors and outcomes, as will be conducted on MILESTONE cohort data, non-representativeness is less relevant, even if the sample is biased at baseline. Drawing conclusions on the relationships between variables is possible when all potential variables on which a selection could have taken place, such as severity of psychopathology or parental educational level, are controlled for in the analyses.

Future analyses on MILESTONE cohort data will therefore include these variables and potential confounders as covariates. Additionally, we will apply multiple imputation under the assumption of ‘missing at random’, as we hypothesise missingness is primarily related to constructs that we have assessed, such as self-reported problem levels and clinician-rated severity of psychopathology.

Finally, the reliability of clinical diagnostic classifications has been debated because clinicians usually do not obtain their information through standardised assessment procedures. Clinical classifications are therefore reported in broader categories (ie, depressive disorders), rather than subtypes (ie, major depressive disorder, single episode).

It is important to note that although the MILESTONE study was conducted in multiple countries, making country comparisons was not the purpose of the study, as they have been described elsewhere. Instead, this cohort study aims to describe what type of care young people receive after reaching the upper age limit of their CAMHS independent of site or country-specific factors. Country comparisons cannot be made validly: the subsamples within countries are not representative of the clinical populations of those countries, which limits opportunities to relate our findings to country-specific characteristics such as transition policy and service organisation. This was complicated further by the lack of formally described transition policies within CAMHS and countries.

Future plans
Recruitment of CAMHS users within this wide range of services across eight countries resulted in a heterogeneous patient-population, which is very suitable for our aim to describe how sociodemographic and clinical characteristics are associated with the type of care young people receive in the 2 years after reaching the upper age limit of their CAMHS, beyond culture, mental health systems and transition policy. Analysis of longitudinal data from the MILESTONE cohort will be used to assess relationships between the demographic and clinical characteristics of young people reaching the upper age limit of the CAMHS they receive treatment at and the CAMHS clinician’s recommendation to transition from CAMHS to AMHS. Additionally, we will assess the relationship between demographic and clinical characteristics and type of care the young person uses over the next 2 years, such as whether the young person transitions to AMHS. Finally, at 2 years follow-up, the mental health outcomes of young people following different care pathways will be compared.

COLLABORATION
The MILESTONE consortium invites researchers to contact the corresponding author for requests for statistical code used, instruments used and anonymised data.

Acknowledgements We thank all the young people, parents/carers and clinicians for participating in the MILESTONE study. We would also like to extend our thanks.
to the teams within the collaborating CAMHS and AMHS. We extend a special thanks to the young project advisors and the members of the MILESTONE Scientific Clinical and Ethical Advisory Board and Jane Warwick. We also thank everyone who was temporarily part of the wider MILESTONE team, as well as all the students who contributed to the data-collection. Finally, we thank all members of the wider MILESTONE consortium for their contribution.

Collaborators The wider MILESTONE consortium includes the following collaborators (including the members listed as authors): Laura Adams, Giovanni Alliborio, Marco Armando, Sonja Asian, Nadia Baccanelli, Monica Balauido, Fabia Bergamo, Jo Berriman, Chrystele Bodier Rethore, Frédérique Bonnet-Brihault, Albert Boon, Karen Braamse, Ulrike Breuninger, Maarja Buttiglione, Sarah Butter, Marco Cammarano, Alastair Canaway, Fortunata Cantini, Cristiano Cappellari, Marta Carini, Giuseppe Carrà, Isabelle Charvin, Krizia Chianura, Philippa Coleman, Annalisa Colonna, Patrizia Conese, Raffaella Costanzo, Claire Coster, Marina Danckaerts, Andrea de Giacomo, Peter Dineen, Jean-Pierre Erans, Alan Farmer, Jörg M Fegert, Alessandro Ferrari, Sabrina Ferrari, Giuliana Galea, Michela Gatta, Elisa Gheza, Giacomo Goglia, MariaRosa Grandetto, James Griffin, Elaine Healy, Keith Holmes, Véronique Humbertclaud, Nicola Ingravallo, Roberta Inverzini, Renaud Jardri, Helen Keeley, Coimhe Kelly, Meghan Killillie, James Kirwan, Catherine Klockaerts, Vlatka Kovač, Hélène Lida-Pulik, Ashley Llew, Christel Lippens, Fionaunnela Lynch, Francesco Macchi, Lidia Manenti, Francesco Margarini, Lucia Margari, Paola Martellini, James McDonald, Leighton McFadden, Deny Menghini, Maria Migone, Sarah Miller, Emiliano Monzani, Giorgia Morini, Torod Mutofu, Renata Nacinovich, Cristina Negrinotti, Emmanuel Nels, Francesca Neri, Paulina Nikolova, Marzia Nossa, Michele Noterdaeme, Francesca Operto, Vittoria Panaro, Ayes Parenti, Adriana Pastore, Vinutha Pemmaraju, Ann Pepermans, Maria Giuseppina Petruzzelli, Anna Prescici, Catherine Prigent, Francesco Rinaldi, Erika Riva, Laura Rivolta, Anne Roekens, Ben Rogers, Pablo Ronzini, Vebhi Sakar, Selena Salvetti, Vanveer Sandhu, Renate Scheger, Paolo Scoccio, Marco Siviero, Michael Slowik, Courtney Smyth, Maria Antonietta Spadone, Mario Speranza, Paolo Stagi, Pamela Stagni, Fabrizio Starace, Patrizia Stoppa, Lucia Tansini, Cecilia Tosselli, Guido Tochetti, Maria Tubito, Arno van Dam, Hanne Van Gutshoven, Dirk van West, Fabio Vanni, Chiara Vannicola, Cristina Varuzza, Pamela Varvara, Patrizia Ventura, Stefano Vicari, Stefania Vicini, Carolin von Bentzel, Philip Wells, Beata Williams, Anna Wilson, Marina Zarabarella, Anna Zamboni & Edda Zanetti.

Contributors SEG prepared the first draft and subsequent versions of this manuscript, under supervision of GCD, AM and FCV and in collaboration with LSvB, MMO and DW. SPS, AM, GDG, PS, JM, FM, DP-O, ST, UMES, TF, CS, MP, DW, FCV and GCD conceived the original study design, obtained funding and/or acted as principal investigators. HT was the study coordinator.
