Microtubules are polymerized dimers of α- and β-tubulin that underlie a broad range of cellular activities. Acetylation of α-tubulin by the acetyltransferase ATAT1 modulates microtubule dynamics and functions in neurons. However, it remains unclear how this enzyme acetylates microtubules over long distances in axons. Here, we show that loss of ATAT1 impairs axonal transport in neurons in vivo, and cell-free motility assays confirm a requirement of α-tubulin acetylation for proper bidirectional vesicular transport. Moreover, we demonstrate that the cellular pool of ATAT1 is transported at the cytosolic side of neuronal vesicles that are moving along axons. Together, our data suggest that axonal transport of ATAT1-enriched vesicles is the predominant driver of α-tubulin acetylation in axons.

INTRODUCTION

Neurons are polarized cells, structurally and functionally divided into somatodendritic and axonal compartments. Axons are often long and characterized by intense bidirectional microtubule (MT)–dependent transport of cargos to control critical functions, including cell survival and neurotransmission. Cargos such as vesicles and membrane organelles (e.g., mitochondria, endosomes, and lysosomes) as well as proteins and messenger ribonucleoprotein complexes are loaded on molecular motors to undergo axonal transport along MTs. The anterograde transport is powered by the kinesin superfamily, while retrograde transport involves cytoplasmic dynein (1). Posttranslational modifications (PTMs) of MTs have been suggested to modulate axonal transport (2, 3). Specifically, the acetylation of MTs may contribute to this process by enhancing the recruitment of kinesin and dynein and their mobility (4, 5). Moreover, increasing MT acetylation improves the transport deficits resulting from mutations in Huntingtin and LRRK2 genes (4, 6). The acetylation of α-tubulin in MTs is driven by the α-tubulin N-acetyltransferase 1 (ATAT1)/MEC17 (7, 8). Recent in vitro experiments performed with recombinant ATAT1 have suggested that it can enter the lumen of MTs from their extremities and/or lateral imperfections (9, 10) and passively diffuses to promote acetylation of α-tubulin K40 residues (11, 12). However, it remains unclear how ATAT1 reaches and acetylates MTs in living cells. This question is particularly important in neurons where axons and dendrites cover long distances with rather homogenously acetylated MTs. To decipher how ATAT1 promotes MT acetylation in neurons, we combined cell-free assays with cellular and molecular analyses of ex vivo (organotypic slices) or cultured mouse cortical projection neurons (in microfluidic chambers) and motoneurons of Drosophila larvae in vivo. Our work unveils the existence of a predominant pool of ATAT1 at the cytosolic side of motile vesicles, whose active transport promotes acetylation of α-tubulin in MTs. Therefore, we propose that the transport of ATAT1-enriched vesicles is a predominant driver of axonal MT acetylation.

RESULTS

Loss of Atat1 interferes with axonal transport in neurons across species

ATAT1 promotes the acetylation of α-tubulin in MTs, a PTM that favors the recruitment of kinesin and dynein and their mobility along axons (4, 5, 13). To test whether loss of Atat1 impairs axonal transport in cortical projection neurons in situ, we performed time-lapse recordings of organotypic brain slices from postnatal (P) day 2 wild-type (WT) mice. For this purpose, embryonic day 14.5 (E14.5) mouse embryos were in utero electroporated (IUE) with a combination of 4OH-tamoxifen (4OHT)–inducible Cre, Cre-inducible short hairpin RNA against Atat1 (shAtat1) (Fig. S1A), Cre-inducible red fluorescent protein, and Lamp1-Emerald plasmids. Successive injections of 4OHT allowed us to identify the callosal projection of IUE neurons and record the transport of Lamp1-Emerald–positive lysosomes (Fig. 1, A and B, and movie S1). We showed that the 4OHT-induced knockdown (KD) of Atat1 in callosal projection neurons 3 days after IUE at E14.5 (to maintain the expression of Atat1 during the migration of projection neurons) impaired both anterograde and retrograde axonal transports recorded at P2 (Fig. 1, A to F, and fig. S1B). The KD of Atat1 led to the reduction of the average and instantaneous velocities (Fig. 1, C and D) and the run length and to the increase of the pausing time of lysosomes (Fig. 1, E and F). These data were confirmed in cortical projection neurons from E14.5 Atat1 knockout mice (Atat1 KO) or their corresponding WT controls (14) cultured for 5 days in vitro (DIV) in microfluidic devices and incubated with fluorescent probes to follow the transport of lysosomes and mitochondria along axonal MTs (Fig. 1, G and H, and movies S2 and S3). The average velocities

Scale bars, 50 μm. (K to L) Histograms showing parameters of axonal transport of lysosomes to analyze average velocity (N), instantaneous velocity (O), run length (P), and pausing time (Q) in mouse cortical neurons cultured 5 DIV from WT or Atat1 KO mouse embryos. Scale bars, 50 μm. (M) Experimental setup for time-lapse recording of axonal transport in E15.5 cortical neurons isolated from E14.5 IUE mouse embryos and cultured 5 days in microfluidic device. N.S., not significant. (N to Q) Histograms showing parameters of axonal transport of lysosomes (LysoTracker) to analyze average velocity (N), instantaneous velocity (O), run length (P), and pausing time (Q) in mouse cortical neurons cultured 5 DIV from E15.5 embryos transfected with WT α-tubulin GFP (Tub-GFP) or acetylation mimic K40Q α-tubulin GFP (K40Q Tub-GFP) together with sh-Scr or sh-Atat1. Description of graphical summaries here within are histograms of means ± SEM, while statistical analyses of (C to F) are two-tailed Mann-Whitney and (I, J, K, L, Q) are Kruskal-Wallis test. Specifically [(C) P < 0.0001 and U = 17,455; (D) P < 0.0001 and U = 3044 and P = 0.0002 and U = 6372 for anterograde and retrograde, respectively; (E) P < 0.0001 and U = 20,972; (F) P < 0.0001 and U = 26,168; (I) P < 0.0001 and K = 54.03; (J) P = 0.0033 and K = 13.74 and P < 0.0001 and K = 36.45 for anterograde and retrograde, respectively; (K) P < 0.0001 and K = 38.29; (L) P < 0.0001 and K = 34.05; (Q) P < 0.0001 and K = 31.88; (O) P = 0.0006 and K = 17.43 and P = 0.0002 and K = 20.19 for anterograde and retrograde, respectively; (P) P < 0.0001 and K = 22.29; and (Q) P < 0.0001 and K = 28.7).
(Fig. 1I and fig. S1, G, M, N, and R), anterograde and retrograde instantaneous velocities (Fig. 1J and fig. S1, H, M, N, and R), and run lengths (Fig. 1K and fig. S1, I, M, N, and R) of moving vesicles and mitochondria were reduced, while their pausing time were increased (Fig. 1L and fig. S1, J, M, N, and R). These modified vesicular parameters were associated with an impairment in the overall flux of organelles in Atat1 KO mice (fig. S1, K, L, M, and N), likely arising from the reduced recruitment of motors onto MTs. Western blotting analyses revealed that lack of ATAT1 expression in newborn cortical neurons resulted in the absence of MT acetylation (fig. S1, O and P) without affecting the expression level of histone deacetylase 6 (HDAC6), the main α-tubulin deacetylase (fig. S1, O and Q). Expression of catalytically active ATAT1–green fluorescent protein (GFP) (15, 16) in cortical neurons from E14.5 WT and Atat1 KO embryos rescued the average velocity (Fig. 1I and fig. S1R), anterograde and retrograde instantaneous velocities (Fig. 1I and fig. S1R), run length (Fig. 1K and fig. S1R), and pausing time (Fig. 1L and fig. S1R) of lysosomes. To confirm that the defects in axonal transport upon down-regulation of Atat1 arise from reduced α-tubulin acetylation, we coexpressed the acetylated mimetic α-tubulin K40Q with shAtat1 (fig. S1S) in projection neurons of WT E14.5 embryos. We isolated the electroporated neurons 1 day after electroporation and cultured them 5 days in microfluidic devices (Fig. 1M). Our recordings showed that expression of α-tubulin K40Q rescued the average and instantaneous transport velocities of lysosomes (Fig. 1, N and O, and fig. S1X) and mitochondria (fig. S1, T, U, and Y), as well as their run lengths (Fig. 1P and fig. S1, V, X, and Y) and pausing time (Fig. 1Q and fig. S1, W, X, and Y) resulting from Atat1 KD at E14.5.

We further examined whether the role of ATAT1 in axonal transport is conserved in vivo in Drosophila melanogaster. We assessed the transport of synaptotagmin–GFP vesicles in axons of third-instar larva motoneurons (Fig. 2, A and B, and movie S4) upon RNA interference (RNAi)–mediated KD of Atat1/2 (the orthologs of mouse Atat1 in D. melanogaster). Individual KDs of Atat1 and Atat2 were not compensated by expression of other α-tubulin acetylation regulators (fig. S2, A and B) and led to the reduction of average velocity (Fig. 2C and fig. S2C), anterograde and retrograde instantaneous velocities (Fig. 2D and fig. S2C), as well as run length (Fig. 2E and fig. S2C) of synaptotagmin–GFP vesicles, with associated increase of their pausing time (Fig. 2F and fig. S2C). The transport defects were not resulting from global protein aggregation along axons (fig. S2D) but were more likely associated with the decreased acetylation of MTs (Fig. 2, G and H). This was further supported by a genetic rescue of axonal transport upon concomitant depletion of the main α-tubulin deacetylase Hdac6 (17) (fig. S2E) in motoneurons from individual KD of Atat1 or Atat2 larva (Fig. 2, C to F, and fig. S2C), where residual Atat activity can promote MT acetylation (Fig. 2, G and H). These data were also supported in the third-instar larval axons for 30 min before recordings with 10% sucrose solution containing tubastatin (TBA), a specific inhibitor of HDAC6 (18), which rescued all measured axonal transport parameters (Fig. 2, I to L, and fig. S2F).

Impaired axonal transport in larvae or adult fly motoneurons leads to locomotor behavior defects (18). We thus monitored the climbing index of adult flies as well as the crawling speed and peristaltic body-wave frequency of their larvae as functional readouts of single or combined KD of Atat1/2 (6, 19). These motoneuron-dependent activities were affected upon conditional KD of Atat1/2 expression (Fig. 2, M to O) and were rescued by either a concomitant genetic depletion of Hdac6 (Fig. 2, M to O) or inhibition of HDAC6 activity using TBA (Fig. 2, P and Q). The disruption of motor behaviors was most likely a consequence of fast axonal transport defects, since we did not observe morphological changes at the neuromuscular junctions’ synapses (fig. S2, G and H) and the RNAi-mediated KD was restricted to motoneurons (see Materials and Methods). Together, these data support that ATAT1 promotes the acetylation of axonal MTs across vertebrate and invertebrate species and that acetylation of the MTs tracks is an important regulator of fast axonal transport.

We next assessed in a cell-free in vitro molecular transport assay how the reduction of K40 acetylation on MTs affects bidirectional axonal transport. For this purpose, purified vesicles were added to in vitro polymerized and polarity-marked MTs (to determine transport directionality), where 10% of rhodamine-labeled (acetylated) tubulin were mixed with either unacetylated tubulin from Atat1 KO mouse brains or with endogenously acetylated tubulin from WT littermates (control) (Fig. 3, A and B, and movie S5). While MTs from Atat1 KO mouse brains were lacking acetylation (20), they were not showing defects of polyglutamylation, glutamylation, tyrosination, or the abundance of Δ2 tubulin PTMs (Fig. 3C). In vitro transport analyses showed that vesicles’ anterograde and retrograde instantaneous velocities (Fig. 3D and fig. S3A), together with their run lengths (Fig. 3E and fig. S3A), were reduced when vesicles were transported along Atat1 KO brain-derived MTs as compared with acetylated MTs isolated from WT brains. These data were comparable to the one obtained in neurons in vitro and in vivo (Figs. 1, D and E, and 2, D and E) and further demonstrate that loss of α-tubulin K40 acetylation impairs MT-dependent transport.

**Atat1 is transported along MTs at the external surface of motile vesicles**

Axons and dendrites are highly enriched in long-lived MTs, whose acetylation depends on ATAT1 distribution and activity. In vitro experiments have previously reported that recombinant ATAT1 undergoes slow and passive diffusion inside MT lumen (12). However, it remains unclear how ATAT1 reaches the MTs in living neurons; thus, we studied its axonal distribution in cultured cortical neurons isolated from E14.5 mice. Mouse cortical neurons were transfected with a combination of plasmids coding for brain-derived neurotrophic factor (BDNF)–mCherry and ATAT1–GFP and cultured 5 DIV. Analysis by superresolution microscopy revealed a punctate distribution of ATAT1 along axons, partially overlapping with the dense core vesicle marker BDNF, suggesting a possible vesicular enrichment of ATAT1 (Fig. 4A). The vesicular enrichment of ATAT1 was further confirmed in cultured human projection neurons derived from pluripotent stem cells, showing that expression of endogenous ATAT1 broadly codistributes with lysosomes (LAMP1 positive) and precursors of synaptic vesicles (SV2C and synaptophysin positives) along their axon (Fig. 4B).

To confirm the vesicular expression of ATAT1, we performed liquid chromatography–tandem mass spectrometry (LC-MS/MS) on vesicular extracts isolated from the cortex of newborn mice. The analysis of the vesicular enriched fraction detected 3648 proteins whose overlap with published vesicular proteomes was, in average, 75% (21–23) (Fig. 4C). These analyses showed that ATAT1, but not HDAC6, is detected together with kinesins and dyneins in a mid-range fraction of the vesicular proteomic content (Fig. 4D and table S1). Western blot analysis of the subcellular fractions obtained from

Description of graphical summaries here within are histograms of means ± SEM, while statistical analyses of (C, D, E, F, H, I, J, K, and L) are Kruskal-Wallis and (M to Q) is one-way analysis of variance (ANOVA). Specifically [(C) P < 0.0001 and K = 60.10; (D) P < 0.0001 and K = 65.80 and P < 0.0001 and K = 76.02 for anterograde and retrograde respectively; (E) P < 0.0001 and K = 25.39; (F) P < 0.0001 and K = 9.6; H, P < 0.0001 and K = 30.09; (I) P < 0.0001 and K = 121.1; (J) P < 0.0001 and K = 62.57 and P < 0.0001 and K = 50.04 for anterograde and retrograde, respectively; (K) P < 0.0001 and K = 24.3; (L) P < 0.0001 and K = 12.96, M, P < 0.0001 and F(4, 58) = 34.55; (N) P < 0.0001 and F(4, 55) = 24.3; (O) P < 0.0001 and F(4, 33) = 45.61; (P) P < 0.0001 and F(7, 71) = 27.29; and (Q) P < 0.0001 and F(7, 83) = 47.65]. In addition, post hoc multiple comparisons for (C, D, E, F, H, I, J, K, and L) Dunnett’s tests, for (M to Q) is Dunnett’s test and are *P < 0.05, **P < 0.01, ***P < 0.001, and ****P < 0.0001. The total number of samples analyzed were as follows: (C to F) 110 to 276 vesicle tracks from 7 to 12 larvae per group; (H) 6 to 8 larvae per group; (I to L) 112 to 161 vesicle tracks from 6 to 8 larvae per group; (M and N) 9 to 18 larvae per group; and (P and Q) 8 to 9 larvae per group.
Together, these data suggest that the amino acid sequence of ATAT1 more efficiently raising the level of
Moreover, expression of the vesicular-enriched ATAT1 isoforms was preferentially localized in the cytosol (P3/S3 < 1) (Fig. 4K).
These constructs were next used to transfect human embryonic kidney (HEK) 293 cells and analyzed for their subcellular localization in purified vesicles extracts (fig. S4A), and Western blott (WB) performed on mice cortical brain extracts only detected the presence of ATAT1 isoforms 3 and 4 (Fig. 4E), suggesting that the AP2 binding domain (amino acids 307 to 387) is required for both its vesicular enrichment and efficient α-tubulin acetylation. To decipher whether ATAT1 is encapsulated within the intravesicular lumen and/or associated with the extravesicular membrane, we performed a mild proteinase K digestion to remove protein anchored at the external surface of vesicles (26). The treatment led to a dose-dependent reduction of ATAT1 and dynein intermediate chain (DIC) without altering levels of the intravesicular protein α-synuclein (Fig. 4N) (26). Together, these data suggest that ATAT1 is enriched at the cytosolic side of moving vesicles, from where it may be released in vicinity of MTs to promote α-tubulin acetylation and modulate axonal transport.
The vesicular pool of Atat1 controls axonal transport by promoting acetylation of MTs
We first performed LC-MS/MS on vesicular extracts isolated from the cortex of newborn WT or Atat1 KO mice to check whether loss of Atat1 interferes with axonal transport by altering the vesicular proteome. The analysis revealed that, from 44 differentially detected proteins (fig. S5A and table S2), none of the 29 molecular motor proteins (fig. S5B and table S3) nor the 16 glycolytic enzymes (fig. S5C and table S4) were significantly affected by lack of Atat1 expression. Moreover, gene ontology (GO) data analysis of the differentially detected proteins did not reveal significantly enriched processes, function, or cellular component upon Atat1 loss in vesicular extracts. Since we did not detect any differences of the Atat1 KO vesicular proteome that can explain the reduction of MT acetylation, we hypothesized that Atat1-enriched vesicle displacement on MTs might be required for their acetylation. To test this hypothesis, we cultured mouse cortical neurons with the cytoplasmic dynein inhibitor ciliobrevin D (20 μM) (27) to disrupt axonal transport of vesicles. This led to a mild reduction (33%) of MT acetylation in the soma of the neurons (Fig. 5, A and B) and a severe reduction (67%)
**Fig. 4. To test whether the vesicular pool of Atat1 promotes the acetylation of \( \alpha \)-tubulin in MTs, we isolated subcellular fractions from newborn mouse cortices and then assessed their ability to promote the acetylation of nonacetylated MTs isolated from HeLa cells (8), compared with endogenously acetylated bovine brain MTs (control) (Fig. 6A). We observed that most of the MT acetyltransferase activity was detected in the vesicular fraction (Fig. 6B), an activity that was lost in either vesicles isolated from Atat1 KO mice or vesicles incubated without acetyl–coenzyme A (CoA), the acetyl group donor for Atat1-dependent MT acetylation (Fig. 6, C to E) (15). Moreover, the vesicular fraction was able to promote the acetylation of MTs over several hours in vitro, as suggested by the strong reduction of CoA release upon incubation with vesicles from Atat1 KO mice, as compared to WT control (Fig. 6F). These findings suggest that the
Fig. 6. Vesicles predominantly promote α-tubulin acetylation via ATAT1. (A) WB analysis of purified tubulin from bovine brain and HeLa cells, showing acetylated α-tubulin (Ac α-Tub). Ponceau red identified total α-tubulin (Tot α-Tub) on corresponding extracts. (B and C) In vitro enzyme-linked immunosorbent assay (ELISA)–based α-tubulin acetylation assay of polymerized nonacetylated MTs from HeLa cells; incubated with subcellular fraction (B); or with vesicular fractions isolated from WT or Atat1 KO mouse brain cortices with acetyl-CoA or vehicle (C). Purified bovine endogenously acetylated MTs served as control. (D and E) α-Tubulin acetylation assay of in vitro polymerized nonacetylated MTs from HeLa cells incubated with vesicular fractions (P3) isolated from WT or Atat1 KO mouse brain cortices and acetyl-CoA or vehicle. Purified bovine endogenously acetylated MTs served as control. Fluorescent signal was measured for total α-Tubulin by using rhodamine dye and for acetylated α-Tubulin by immunolabeling. Scale bar, 2 μm. (F) In vitro α-tubulin acetylation assay based on CoA release from acetyl-CoA by incubating vesicles from WT or Atat1 KO mice with polymerized nonacetylated MTs from HeLa cells. (G) Scheme depicting the axonal transport (anterograde and retrograde) of vesicles enriched in ATAT1 at their external surface. The proper acetylation of MTs is linked to the axonal transport of these vesicles and we propose that axonal transport transiently disrupt the MT lattice by creating transient openings through which ATAT1 relocates intralumenally to promote K40 α-tubulin acetylation. Description of graphical summaries here within are histograms of means ± SEM, while statistical analyses of (B and C) are one-way ANOVA; (D) is Kruskal-Wallis and (F) is two-way ANOVA. Specifically (B) \( P < 0.0001 \) and \( F(4,35) = 35.56; \) (C) \( P < 0.0001 \) and \( F(4,38) = 158.3; \) (E) \( P < 0.0001 \) and \( K = 120.8; \) (F) \( P < 0.0001 \) and \( F(1,3360) = 8113 \) In addition, post hoc multiple comparisons are Sidak’s tests (B and C); Dunn’s test (D); ****\( P < 0.0001 \). The total number of samples analyzed were as follows: (B and C) eight subcellular brain cortical fractions from eight newborn mice; (E) = 29 to 46 MTs, (F) 240 sample points (1/min) of purified vesicles from three WT and three Atat1 KO mouse brain cortices.
pool of vesicular Atat1 provides an enzymatic activity that promotes MT acetylation and thereby fast axonal transport (Fig. 6G).

**DISCUSSION**

Here, we show that loss of Atat1(/2), thereby MT acetylation, impairs bidirectional axonal transport in mouse cortical neurons in culture or in organotypic slice as well as in fly larva motoneurons in vivo, ultimately resulting in locomotor defects in adult flies. Our work revealed the existence of a large pool of functional Atat1 at the external surface of different types of motile vesicles, including lysosomes and precursors of synaptic vesicles. Moreover, blocking MT-dependent transport impaired α-tubulin acetylation, further suggesting that Atat1-enriched vesicles have to be transported along MT to promote α-tubulin acetylation. Treatment with high concentration of ciliobrevin D (that blocks both retrograde and anterograde transport; Table 1. List of antibodies and their dilution used for ELISA assays, immunostainings, and/or Western blottings.

MATERIALS AND METHODS

Mice

Mice were euthanized and brain cortices were harvested either at P0 or P2 for biochemical analysis or E14.5 for preparation of cortical neuronal cultures. Atat1+/− mice were used to obtain WT and KO mice (14). Mice were maintained with access to food and water ad libitum and kept at a constant temperature (19° to 22°C) and humidity (40 to 50%) on a 12:12-hour light/dark cycle according to the guidelines of the Belgian Ministry of Agriculture and in agreement with the European Community Laboratory Animal Care and Use Regulations (86/609/CEE, Journal Officiel des Communautés Européennes L358, 18 December 1986). All experimental procedures were performed in strict accordance with the recommendations of the European Community (86/609/EEC) for care and use of laboratory animals under the supervision of authorized investigators.

D. melanogaster maintenance and lines

Flies were kept at a 25°C incubator with a 12-hour light and dark cycle. Crosses were performed at 25°C, first-instar larvae were transferred to a 29°C incubator until use. For axonal transport, behavioral experiments and immunolabeling D42-Ga4-UAS:Syt1-GFP or D42-Ga4 virgin females were crossed with upstream activation sequence (UAS)–RNAi carrying lines. For quantitative polymerase chain reaction (qPCR) analysis, elav-Ga4 females were crossed with UAS-RNAi males. All RNAi inserts sequences were validated by Sanger sequencing.

Drosophila lines were acquired from the Vienna Drosophila Resource Center (VDRC) and the Bloomington Drosophila Stock Center (BDSC). UAS-Syt1-GFP (BDSC 6925), UAS-RNAi Atat1 (VDRC CG3967), UAS-RNAi Atat2 (VDRC CG17003), UAS-RNAi Hdac6 (BDSC 51181), and UAS-RNAi Zpg (VDRC CG10125) were used as control. Elav-Ga4 (BDSC 458) or D42-Ga4 (BDSC 8816) flies were used for specific activation of a UAS sequence in postmitotic neurons or motor neurons, respectively. All RNAi insert sequences were validated by Sanger sequencing.

Constructs

BDNF-mCherry was previously used in (24) and Atat1-GFP (27099), pCALNL-DsRed (13769), and pEGFP α-tubulin K40Q (105302) were purchased from Addgene (www.addgene.org/). pEGFP-Tub was obtained from Clontech (www.takarabio.com/). pCAG mito-DsRED and pCAG truncation constructs, FLAG-ATAT1(amino acids 1 to 333), FLAG-ATAT1(amino acids 1 to 196) were synthesized by X. Coumoul. Lis1 shRNA sequence was 5′-GAGATGAACTA-GGATGAACTA-3′ (30). Atat1 sequence was inserted in pBS/U6- ploxPneo plasmid (provided by X. Coumoul). Lis1 shRNA sequence was 5′-GACGAAATCATGACTATGTTTGT-3′ (30). Atat1 truncation constructs, FLAG-ATAT1(amino acids 1 to 333), FLAG-ATAT1(amino acids 1 to 286), FLAG-ATAT1(amino acids 1 to 242), and FLAG-ATAT1(amino acids 1 to 196) were synthesized as gBlocks and inserted to a pCIG2 vector. The Atat1 short hairpin RNA (shRNA) sequence was 5′-GCACGAAATCATGACTATGTTTGT-3′ (30). Atat1 sequence was inserted in pBS/U6-ploxPneo plasmid (provided by X. Coumoul). Lis1 shRNA sequence was 5′-GGATGAACTAATCGAGATGAACTA-3′ (30) and was subcloned in pCA-b-EFPPm5 silenced 3, a gift from M. Vermeren (King’s College London, UK). All construct sequences were verified by Sanger sequencing.

Cell lines culture, transfections, and drug treatment

Mouse neuroblastoma N2A cells were cultured in Dulbecco’s modified Eagle’s medium (DMEM) (Gibco) supplemented with 10% fetal calf serum at 37°C with 5% CO₂. To test shAtat1 efficiency, we treated N2A cells with 4OHT (1 μM) 24 and 48 hours after lipofection with Lipofectamine 2000 (Invitrogen), and cell lysis or fixation was performed 48 hours after the first treatment with 4OHT.

Neuronal cell culture

E14.5 mouse brain cortices were dissected and mechanically dissociated in Hanks’ balanced salt solution (HBSS) (Sigma-Aldrich, H6648)
supplemented with 1.5% glucose. Cells were cultured at a confluence of ~70% with Neurobasal Medium (Gibco, Invitrogen, 21103049) supplemented with 2% B27 (Gibco, Invitrogen, 17504044), 1% penicillin/streptomycin (Gibco, Invitrogen, 15140122), and 1% GlutaMAX (Gibco, Invitrogen, 35050061) at 37°C. Nucleofections of E14.5 cortical neurons were performed using Mouse Nucleon Nucleofector Kit (VPG-1001, Lonza) according to the manufacturer’s protocol.

**Human-induced pluripotent stem cell culture and generation of cortical projection neurons**

Human embryonic stem cell research and protocols were approved by the Ethics Committee of the University of Liège (no. B70720096466); all experiments were conducted according to its guidelines. Human-induced pluripotent stem cell (hiPSC) line GM23446 (Coriell Institute) was maintained on Geltrex-coated dishes (Gibco) in DMEM/F12 supplemented with 20% KO serum replacement (Gibco), 100 μM nonessential amino acids (NEAA) (Gibco), 100 μM 2-mercaptoethanol, and basic fibroblast growth factor (100 ng/ml; PeproTech, London, UK), conditioned on γ-irradiated mouse embryonic fibroblasts. Cells were passaged routinely with collagenase A (1 mg/ml; Roche).

Generation of human cortical neurons was performed as described in (39). Briefly, hiPSCs were dissociated with TrypLE (Gibco) for 4 min at 37°C and cultured on Geltrex-coated dish in pluripotent medium (Cell Guidance Systems) until they reached confluence. Neuronal induction was triggered with media making use of dual SMAD inhibition and tankyrase inhibitor to enhance forebrain fate: DMEM/F12 containing N2 (Gibco), B27 (Gibco), penicillin/streptomycin (1:100; Gibco), glucose (0.8 mg/ml; Carl Roth HN06.2), NEAA, GlutaMAX (Gibco), cyclic adenosine 3′,5′-monophosphate (0.15 ng/ml; Sigma-Aldrich, A9501-1G), 500 nM A83-01 (Miltenyi Biotec, 130-103-925), and 2 μM XAV939 (Enzo Life Sciences, BML-WN100-0005). Medium was changed daily, and cells were passaged at day 8 with 0.5 M EDTA. Cells were maintained until day 18 and replated at a density of 12,000 cells/cm² in neural differentiation media containing 1:1 DMEM/F12/Neurobasal, N2, B27, penicillin/streptomycin, glucose (0.8 mg/ml), NEAA, and GlutaMAX. Neural differentiation media were changed every other day, and Geltrex (1:100) was added 4 days before fixation with 4% paraformaldehyde (PFA) at day 32 to prevent detachment of the neurons.

**Immunofluorescence**

Mouse cerebral cortical neurons, N2A cells, HeLa S3 cells, and human projection neurons derived from hiPSCs were fixed using 4% PFA for 20 min at room temperature (RT) and washed with phosphate-buffered saline (PBS) + 0.3% Triton X-100. Antigen retrieval was performed for nucleofected cerebral cortical neurons using 10 mM buffered saline (PBS) + 0.3% Triton X-100, 200 nM LDN-193189 (Miltenyi Biotec, 130-103-925), and 5 μM trichostatin A (Sigma-Aldrich, T8552). Subsequently, samples were boiled and reduced by 5 min of incubation at 70°C with loading buffer and were loaded on SD–polyacrylamide gel electrophoresis gel to be finally transferred to a nitrocellulose membrane. For α-tubulin acetylation analysis, 2 μg of protein lysate was loaded on a gel; for analysis of all other proteins, 30 μg of lysate was used. Membranes were imaged using Amersham Imager 600 (General Electric, 29083461), and band densitometry was measured using ImageJ.

**Subcellular fractionation**

Subcellular fractionation of a frozen mouse brain cortex or cultured HEK293 cells was performed as previously described (24).

**MS analysis**

All chemicals were purchased from Sigma-Aldrich unless stated otherwise. Pellets from three independent samples of vesicles isolated from the brain cortex of WT or Atat1 KO mice were solubilized using 5% SDS. Samples were then loaded onto the commercial S-Trap columns (Protifi, USA); for washing the detergents, reduction with 5 mM dithiothreitol (DTT), 10 mM iodoacetamide, and overnight digestion with trypsin (Promega) at 50:1 protein:trypsin ratio. Eluted peptides were dried using a vacuum centrifuge and stored in ~80°C. Ultra LC/MS grade solvents were used for all chromatographic steps. Each sample was loaded using splitless nano ultraperformance LC (UPLC) (10 kpsi nanoACQUITY; Waters Corporation, Milford, MA, USA). The mobile phase was as follows: (A) H₂O + 0.1% formic acid and (B) acetonitrile + 0.1% formic acid. Desalting of the samples was performed online using a Reversed-Phase Symmetry C18 trapping column (internal diameter of 180 μm, 20 mm in length,
and 5 µm particle size; Waters Corporation). The peptides were then separated using a T3 High Strength Silica nanocolumn (internal diameter of 75 µm, 250 mm in length, and 1.8-µm particle size; Waters Corporation) at 0.35 µl/min. Peptides were eluted from the column into the mass spectrometer using the following gradient: 4 to 30% B in 155 minutes, 30 to 90% B in 5 min, maintained at 90% for 5 min, and then back to initial conditions. The nanoUPLC was coupled online through a nanoelectrospray ionization emitter (10-µm tip; New Objective, Woburn, MA, USA) to a quadrupole orbitrap mass spectrometer (Q Exactive Plus, Thermo Fisher Scientific), using a FlexIon nanospray apparatus (Proxeon). Data were acquired in a data-dependent acquisition mode, using a top 10 method. MS1 resolution was set to 70,000 [at 200 mass/charge ratio (m/z)], mass range of 300 to 1650 m/z, and AGC of 3e6, and maximum injection time was set to 60 ms. MS2 resolution was set to 17,500, quadrupole isolation 1.7 m/z, AGC of 1e5, dynamic exclusion of 60 s, and maximum injection time of 60 ms. Raw data were processed with MaxQuant v1.6.0.16. The data were searched with the Andromeda search engine against the SwissProt human proteome database appended with common lab protein contaminants and the following modifications: carbamidomethyl on C and oxidation of M. Quantification was based on the Label-free quantitation method, based on unique peptides. t test with the Holm-Sidak method for multiple comparison was used for determination of statistical significance after logarithmic transformation. GO data analysis of the differentially detected proteins was done using GOrilla tool (40) (http://cbl-gorilla.cs.technion.ac.il), using two ranked lists and a P value of 10 × 10−3 as threshold.

**Proteinase K sensitivity assay**

Proteinase K sensitivity assay was performed as previously described (26). Fifty micrograms of vesicles (P3) were incubated with increasing concentration of proteinase K to reach a final concentration of 0.05, 0.25, 1.25, and 6.25 µg/µl in digestion buffer (10 mM Hepes, 10 mM KCl, 2 mM EGTA, and 300 mM sucrose) in a total volume of 50 µl, for 30 min at 37°C. To end the reactions, 5 mM phenylmethylsulfonyl fluoride (PMSF) with Laemmli buffer, followed by immediate boiling and reduction of the samples in 95°C for 5 min.

**Microfluidics device fabrication and axonal transport recordings in mice cortical neurons and Drosophila third-instar larvae**

Microfluidics devices were prepared as described in (41). Axonal transport recording was performed after 5 DIV, as previously described (16), using an inverted confocal microscope (Nikon, A1Ti), at a 600-ms interval for 60 s using 60× lens. For cell culture, the recording microscope chamber was heated at 37°C and supplied with 5% CO₂.

**Locomotor activity and climbing assay**

Larval locomotion assays were performed by placing third-instar D. melanogaster larvae in the center of 15-cm petri dishes coated with 3% agar (42). Millimeter paper was glued below each 15-cm petri dish to quantify distance traveled. Crawling speed was extrapolated from distance traveled in 1 min; peristaltic activity was defined as complete posteriorocontinerction of the larvae in 1 min. Climbing assay for adult flies was performed as previously described in (43). Ten flies per group were allowed to climb an empty polystyrene tube for 1 min in three sequential assays. Climbing index was defined as average ratio successful climbs over 15 cm of the total number of flies in a group.

**Lysosome transport analysis in organotypic slice**

Mice purchased from Janvier were anesthetized with isoflurane (Abbott Laboratories) in an oxygen carrier before the administration of temgesic (Schering-Plough). Endotoxin-free plasmids were injected into lateral ventricles of E14.5 mouse embryo forebrains using a FemtoJet microinjector (Eppendorf) with 0.1% fast green for visualization. Injection was followed by electroporation (5 pulses of 24 mV at 50-ms intervals for 950 ms) using platinum electrodes (Sonidel, catalog no. CUY6503) connected to an electroporator (ECM 830, BTX). Embryos were coelectroporated with tamoxifen-inducible CreERT2 expressing plasmid along with two Cre-dependent constructs expressing DsRed and shAtat1/sh-scrambled and with LAMP1-Emerald–expressing plasmid. After electroporation, embryos were placed back in the abdominal cavity. For injection, 4%HT and progesterone were dissolved in ethanol 100% at concentrations of 20 and 10 mg/ml, respectively, and then diluted with nine volumes of corn oil (Sigma-Aldrich). Diluted tamoxifen solution (2 mg/ml, 100 µl per mouse) was intraperitoneally injected three times at E17, E18, and P1, and pups brains were dissected at P2. Brains were embedded in agarose 4% HBSS solution and cut into coronal sections (300 µm) using a vibratome (Leica VT1000S, Leica Microsystems). The slices were placed on Matrigel-coated (Corning) MatTek glass-bottom dishes and covered with half-diluted Matrigel with supplemented Neurobasal culture medium. Sections were incubated for 30 min at 37°C before imaging. Time-lapse imaging was performed on a Zeiss Super Resolution LSM 880 Airyscan Elyra S1 (×63 magnification) at a 500-ms interval for 60 s at the corpus callosum midline. The recording microscope chamber was heated at 37°C and supplied with 5% CO₂.

**qPCR analysis**

Ten adult fly heads were collected in TRIzol Reagent (Ambion, Life Technologies), followed by RNA extraction performed using the manufacturer’s instructions. After deoxyribonucleoside treatment (Roche), 1 µg of RNA was reverse-transcribed with RevertAid Reverse Transcriptase (Fermentas). qPCR was performed using a LightCycler 480 (Roche), with SYBR Green mix according to the manufacturer’s instructions (Roche). Analysis was done using 2-ΔΔCT method after defining primer efficiencies, Rpl13 and Pkg served for normalization (44). The following primers were used: Rpl13, AGGAG-GCGCAAGAAATC (forward) and CTTGCTGGGATCTCTCTT-GAG (reverse); Pkg, TCCTGAAGGCTCTCAAAACATG (forward) and TCCACCATTTTCTCGAGTCT (reverse); Atat1, CAGTC-CCGCACGCTGAG (forward) and ACCGCCATGGTTGAG-CAGAC (reverse); Atat2, TCCCAAGTCAAGGAGACAC (forward) and TGGCGGAAAGAGTTGCCTTAT (reverse); and Hdad6, CAAG-CCCCAAAATCAGC (forward) and ACCAGTTCTCCCGGC (reverse).

**Ciliobrevin treatment**

Drug treatments of cortical neuronal cultures were performed using 20 µM (Sigma-Aldrich 250401) diluted in dimethyl sulfoxide (DMSO) for 2 hours. For third-instar larva, drugs were fed in 10% sucrose solution supplemented with either 1 mM TBA (Sigma-Aldrich, SML0044) or 800 µM Cilobrevin D and DMSO for 30 min and 2 hours, respectively.

**Purification of tubulin from mouse brains or HeLa cells**

Nonacetylated α-tubulin was obtained from HeLa S3 cells (American Type Culture Collection, CCL-2.2TM) for in vitro acetylation assays.
or from WT and Atat1 KO mouse brains for in vitro transport assay according to the protocol adapted from (45). Cells were lysed in BRB80 [80 mM K+ Pipes (pH 6.8), 1 mM MgCl2, and 1 mM EGTA] supplemented with 1 mM β-mercaptoethanol, 1 mM PMSF, and protease inhibitors at 4°C. The soluble fraction was obtained by ultracentrifugation, followed by tubulin polymerization at 30°C min by adding 1 mM guanosine triphosphate (GTP) and 30% glycerol. MTs were pelleted by ultracentrifugation at 30°C for 30 min and depolymerized in BRB80 at 4°C; soluble tubulin was clarified by ultracentrifugation at 4°C. The second polymerization round was performed for 30 min at 30°C in the presence of high-molarity Pipes to remove mitogen-activated proteins; the MT pellet was sedimented by ultracentrifugation. MTs were then depolymerized in BRB80 at 4°C, and soluble tubulin was clarified and snap-frozen.

In vitro α-tubulin acetylation assays
Half-area 96-well plates (Greiner, 674061) were coated with 5-μg tubulin from HeLa cells or bovine brain (Cytoskeleton, catalog no. HTS02-A) in 25 μl of ultrapure water for 2.5 hours at 37°C, followed by blocking (PBS + 3% BSA + 3% skim milk + 3% FBS) for 1 hour at 37°C, and washing with PBS + 0.05% Tween 20. Twenty-five micrograms of the total, S2, S3, or P3 fractions isolated from the P0 mouse brain cortex were diluted in 2× histone acetyltransferase (HAT) buffer (Sigma-Aldrich, EPI001A) supplemented with protease inhibitor cocktail, 5 μM trichostatin, and 50 μM acetyl-CoA (Sigma-Aldrich, A2056) or vehicle (H2O) were added per well for incubation of 2 hours at 37°C with shaking at 100 revolutions per minute. The wells were washed and incubated overnight with acetylated α-tubulin antibody (1:2000) in blocking buffer (PBS + 0.05% Tween 20 + 3% BSA) at 4°C, and wells were washed and incubated for 2 hours at 37°C with peroxidase-conjugated goat anti-mouse antibody (1:5000) in antibody blocking buffer; following another wash, the samples were incubated with trimethylboron/E (Merck Millipore, ES001), and the reaction was stopped with H2SO4.

CoA release was measured using HAT activity colorimetric assay kit (Sigma-Aldrich, EPI001), as indicated by the manufacturer’s instructions. Twenty-five micrograms of P3 fraction were incubated with 5 μg of tubulin in black-bottom μClear plate (Greiner, 655090) for 4 hours, and signal was measured every minute.

In vitro MT-dependent transport assay
WT or Atat1 KO mouse brain was fractionated in vesicle buffer [10 mM Heps-KOH, 175 mM L-aspartic acid, 65 mM taurine, 85 mM betaine, 25 mM glycine, 6.5 mM MgCl2, 5 mM EGTA, 0.5 mM d-glucose, 1.5 mM CaCl2, and 20 mM DTT (pH 7.2), with protease inhibitors], using increasing centrifugation speed with a final sucrose gradient step to isolate motility vesicles as described in (23). Rhodamine-labeled seeds were prepared by incubating a mix of rhodamine labeled with unlabeled purified tubulin from bovine brain (Cytoskeleton, catalog no. HTS02-A) or HeLa cells (isolated as described above) at a ratio of 1:10 for 1 hour at 37°C. The elongation was carried in GTP-BRB80 buffer (80 mM Pipes, 1 mM MgCl2, 1 mM EGTA, and 1 mM GTP) for 30 min at 37°C, followed by incubation for 20 min with 50 μM Taxol to stabilize MTs.

The in vitro polymerized rhodamine-labeled MTs from WT or Atat1 KO mouse brains were seeded in a flow chamber and purified vesicles diluted in motility buffer [BRB80, 0.5% Pluronic F127, 1 mM Taxol, BSA in BRB80 (10 mg/ml), 1 M DTT, glucose oxidase (0.5 mg/ml), 20 mM Mg-ATP, glucose (15 mg/ml), and catalase (470 U/ml)] were labeled with the green fluorescent lipophilic carbocyanine [DiOC18(3), Thermo Fisher Scientific] tracer, loaded in the chambers with 50 μM acetyl-CoA or vehicle, to acquire using a total internal reflection fluorescence (TIRF) microscope. For immunofluorescence analysis, MTs were fixed after the assay with 100% methanol for 10 min at −20°C, then incubated in blocking solution (PBS + 1% BSA) with acetylated α-tubulin antibody (1:10,000) and goat anti-mouse Alexa 647 antibody (1:1000) for 2 hours at RT. Recordings were performed by using a TIRF microscope (Nikon, Eclipse Ti), at 200-ms intervals, using 60× lens.

Quantification of MT acetylation levels using immunofluorescence
Fluorescence intensity levels were measured by Fiji (https://image.j.net/Fiji/Downloads). Regions of interest of 30 μm long for D. melanogaster, or the complete length for in vitro polymerized MTs, accounting for the full width of the motoneurons/MTs were used. The levels of acetylated α-tubulin and total α-tubulin levels were extracted from mean intensity levels. Background levels were subtracted, and the ratio of acetylated α-tubulin/tubulin was calculated.

Analysis of MT-dependent transport
Kymographs were generated for single blind analysis using ImageJ plugin-KymoToolBox (fabrice.cordelieres@curie.u-psud.fr). For D. melanogaster analysis, StackReg plugin was used to align frames. Vesicles were considered stationary if speed was lower than 0.1 μm/s.

Statistics
All experiments (except WB and quantitative reverse transcription PCR analyses) were performed under single-blinded condition, and statistical analyses were generated with GraphPad Prism Software 6.0 or GraphPad Prism Software 7.0 for proteomic analysis.

SUPPLEMENTARY MATERIALS
Supplementary material for this article is available at http://advances.sciencemag.org/cgi/content/full/5/12/eaax2705/DC1
Fig. S1. Analysis of axonal transport parameters in WT and Atat1 KO mouse.
Fig. S2. Validation of RNAi efficiency, mRNA expression of MTs modifying enzymes, representative kymographs of axonal transport, and protein aggregation in D. melanogaster.
Fig. S3. Kymographs of in vitro transport assay.
Fig. S4. Identified peptides of ATAT1 by LC-MS/MS.
Fig. S5. LC-MS/MS proteomics on vesicular extracts from WT and ATAT1 KO mice.
Fig. S6. Acute KD of Lis1 leads to defect in retrograde transport and dampens the acetylation of MTs.
Table S1. Intensity-ranked proteins in vesicle fractions from WT or Atat1 KO mouse detected by LC-MS/MS.
Table S2. Differentially detected proteins in vesicle fractions from WT or Atat1 KO mouse detected by LC-MS/MS.
Table S3. Identified molecular motors in vesicle fractions from WT or Atat1 KO mouse detected by LC-MS/MS.
Table S4. Identified glycolytic enzymes in vesicle fractions from WT or Atat1 KO mouse detected by LC-MS/MS.
Movie S1. Representative movie of Lamp1-Emerald trafficking in axons of cortical brain slice.
Movie S2. Representative movie of lysosome trafficking in axons located in the distal part of PDMS chambers.
Movie S3. Representative movie of mitochondria trafficking in axons located in the distal part of PDMS chambers.
Movie S4. Representative movie of synaptotagmin-GFP trafficking in motorneurons of third-instar larvae.
Movie S5. Representative movies of vesicles trafficking in vitro over polymerized rhodamine-labeled MTs.
Movie S6. Representative movie of ATAT1-GFP trafficking in axons located in the distal part of PDMS chambers.

design. **Funding:** A.E.’s stay at GIGA Research Institute of the University of Liège was funded by EMBO Short-Term Fellowships (ASTF 174-2016); his stay at F.S.’s lab was supported by TAU Global Research and Training Fellowship, Ela Kodesz Institute, and the Scientific and Academic Cooperation Office of the French embassy in Tel Aviv. A.E., M.S., and M.W.’s research was supported by the Israel Science Foundation (grant no. 1688/16). C.S. was supported by a Postdoctoral fellowship from FRM and by EMBO LTF (ALTF 693-2015). S.T., L.B., L.N., and B.M. are PhD fellow, Postdoctoral fellow, Senior Research Associates and Director from FRS-FNRS, respectively. This work was supported by the FRS-FNRS, the Fonds Léon Fredericq (L.N. and B.M.), the Fondation Médicale Reine Elisabeth (L.N. and B.M.), the Fondation Simone et Pierre Clerdent (L.N.), the Belgian Science Policy [IAP-VII network P7/20 (L.N.) and IAP-VII network P7/10 (B.B.)], and the ERANET Neuron STEM-MCD and NeuroTalk (L.N.); grants from Agence Nationale de la Recherche [ANR-14-CE35-0027-01 PASSAGE (F.S.), ANR-15-JPWG-0003-05 JPNID CIRCPROT (F.S.), ANR-15-IDEX-02 NeuroCoG (F.S.), ANR-10-IDEX-0001-02, and ANR-11-LBX-003 (C.J.) in the framework of the “Investissements d’avenir” program]; the LABEX celtis phybio 8 (C.J.); and the Fondation pour la Recherche Médicale (FRM, équipe labellisée, to F.S.). C.J. is supported by the Institut Curie, the French National Research Agency (ANR) award ANR-17-CE13-0021 and the Fondation pour la Recherche Médicale (FRM) grant DEQ20170336756. J.A.S. was supported by the European Union’s Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant agreement no. 675737 and the FRM grant FDT201904008210. M.M.M. was supported by the Fondation Vaincre Alzheimer (grant no. FR-16055p). **Author contributions:** A.E., G.M., F.S., M.W., and L.N. designed the study. A.E. and G.M. performed and interpreted most experiments. L.B. and S.T. designed and performed ex vivo experiments, contributed to in vitro transport experiments and superresolution imaging, and reviewed the manuscript with the help of coauthors. C.S. performed in vitro motility assays under the supervision of F.S. I.G.-N. contributed to cell cultures, transport experiment in mice, and cloning. R.L.B. contributed to Drosophila work. M.S. contributed to cell cultures and biochemical work. M.M.M. and A.S.J. produced and purified nonacetylated MTs. M.M.M. performed analysis of tubulin PTMs. S.F. maintained Atat1 KO animal colonies and contributed to cortical tissue dissections. N.K. provided technical assistance for molecular biology and mouse husbandry. M.W. and L.N. contributed to data interpretation; and A.E., G.M., M.W., and L.N. wrote the manuscript with input from all coauthors. **Competing interests:** The authors declare that they have no competing interests.

**Data and materials availability:** An earlier version of the work can be found at bioRxiv 542464; doi: https://doi.org/10.1101/542464. All data needed to evaluate the conclusions in the paper are present in the paper and/or the Supplementary Materials. Additional data related to this paper may be requested from the authors.
